## Preface

The goal of this book is to understand geometry of metric spaces $X$ which have structure of trees of hyperbolic spaces. The subject originates in the papers [BF92, BF96] of Bestvina and Feighn, where they proved a combination theorem ${ }^{1}$, stating that under certain conditions such $X$ itself is hyperbolic:

Theorem. Suppose $\mathfrak{X}=(\pi: X \rightarrow T)$ is a tree of hyperbolic metric spaces, where vertex and edge-spaces are uniformly hyperbolic, incidence maps of edge spaces into vertex spaces are uniformly quasiisometric and which satisfies the hallway flaring condition. Then $X$ is a hyperbolic metric space.

In Chapter 2 we give definitions clarifying the result. Informally, the hallway flaring condition means that two $K$-quasiisometric sections of $\mathfrak{X}$ over a geodesic interval $I$ in $T$ "diverge at a uniform exponential rate" as we move along $I$ in one of the two directions. The original proof of this theorem was by verifying that $X$ satisfies the linear isoperimetric inequality. In the book we give a new (and longer) proof under weaker flaring assumption than the one made by Bestvina and Feighn; we name the weakened condition uniform (or, in another version, proper) flaring. Informally speaking, instead of requiring the exponential divergence of sections, we only require some rate of divergence, given by a uniform proper function of the arc-length parameter of $I$. We refer the reader to Theorem 2.58 for the precise statement.

The main benefit of our proof is that it is done by constructing a slim combing of $X$ : We find a family of (uniformly quasigeodesic) paths $c(x, y)$ connecting pairs of points $x, y$ in $X$, satisfying slim triangle property: Given three points $x, y, z \in X$, any one of the three paths $c(x, y), c(y, z), c(z, x)$ is contained in a uniform neighborhood of the union of the two other paths. The description of the paths $c$ is a 6 -step induction summarized in Chapter 7, starting with paths in the trees of spaces of the simplest kind that we call narrow carpets: These are metric interval-bundles over geodesics in $T$ such that one of the interval-fibers has uniformly bounded length. We hope that our method of proof of Theorem has a potential to generalize this theorem to complexes of hyperbolic spaces.

The combing paths $c$ in $X$ are mostly concatenations of $K$-quasiisometric sections of $\mathfrak{X}$ over geodesics in $T$. Thus, we obtain (up to a uniformly bounded error) a description of geodesics in $X$ in terms of its structure as a tree of spaces, i.e. vertex-spaces and sections.

As an application of this description of geodesics, we prove (Theorem 8.46) the existence of Cannon-Thurston maps from Gromov-boundaries of subtrees of spaces $Y \subset X$ to $X$, extending an earlier result by Mitra [Mit98], who proved the existence of CannonThurston maps for the inclusion maps of vertex-spaces into $X$. Mitra's proof (as well as the subsequent work of Mj and Sardar, [MS09]) was, in fact, a guideline for our description

[^0]of geodesics in $X$. However, Mitra's description of geodesics stopped at geodesics connecting points in the same vertex-space (step 3 of our 6-step description), leaving much of the work to be done in general. Furthermore, we analyze in detail the Cannon-Thurston laminations of these maps.

We also refer the reader to the related work of Gautero describing uniform quasigeodesics in groups obtained via combination theorem in a special case in [Gau03] and in [Gau16] for trees of relatively hyperbolic spaces. However, we were unable to follow Gautero's proof. We note, furthermore, that various forms of the Bestvina-Feighn combination theorem for relatively hyperbolic groups and spaces were proven by Dahmani [Dah03], Alibegović [Ali05], Gautero and Lusztig [GL04, GL07] and, in greatest generality, by Mj and Reeves [MR08]. In the book we did not attempt to describe (quasi)geodesics in the relatively hyperbolic trees of spaces. However, we proved the existence of CannonThurston maps for subtrees of spaces $Y \subset X$ in Chapter 9 using techniques of proof for the existence of Cannon-Thurston maps for subtrees of spaces in hyperbolic trees of spaces.

Organization of the book. In Chapter 1 we review basic facts of coarse geometry and geometry of hyperbolic spaces. While most of the material of the chapter is standard and well-known, we included it for the ease of reference in the rest of the book.

In Chapter 2 we discuss definitions of the theory of trees of metric spaces, state and compare different flaring conditions in trees of spaces, formulate our main theorem and prove it in some easier cases, e.g. for quasiconvex amalgamations (Section 2.6.2).

In Chapter 3 we define a certain class of subspaces $Y$ in a tree of spaces $\mathfrak{X}$, called semicontinuous families. These subspaces (each of which also has structure of a tree of hyperbolic spaces $\mathfrak{Y}$ ) have the property that their intersections with vertex-spaces of $\mathfrak{X}$ are uniformly quasiconvex and every point in $Y$ is connected to the intersection $Y_{u}=Y \cap X_{u}$ of $Y$ with a distinguished vertex-space $X_{u}$, by a $K$-quasiisometric section of $\mathfrak{X}$ over an interval in $T$. We prove that the subspaces $Y$ are coarse Lipschitz retracts of $X$, which is a generalization of the horocyclic projections to a geodesic in the hyperbolic plane; its existence was first proven by Mitra, [Mit98, Theorem 3.8] in the case of semicontinuous families called flow-spaces $F l_{K}\left(X_{u}\right)$. Flow-spaces and three other types of semicontinuous families (ladders, carpets and bundles) serve as key tools in our definition of combing paths $c$ in $X$. Ladders are certain (semicontinuous) families of intervals over subtrees in $X$, where semicontinuity (informally) means that the lengths of the intervals can shrink substantially as we move away one edge from a vertex $u$ (the center of the ladder). Bundles should be thought of as continuous families of quasiconvex subsets $Q_{v}$ of vertex-spaces of $\mathfrak{X}$ with two (nonempty) vertex-spaces $Q_{v}, Q_{w}$ uniformly Hausdorff-close, whenever $v$ and $w$ span an edge of $T$.

Chapter 4 primarily deals with Steps $1-3$ of our description of geodesics in $X$ : We describe combing paths in carpets, carpeted ladders and general ladders and establish their hyperbolicity. Hyperbolicity of flow-spaces in proven in Chapter 5, which is technically the most difficult part of our work: We prove the slim triangle property for the combing paths $c$ by analyzing triples of ladders (with the common center $u$ ) in the flow-space $F l_{K}\left(X_{u}\right)$ of a vertex-space $X_{u}$.

Our last challenge is to connect by combing paths points in different vertex-flowspaces $F l_{K}\left(X_{u}\right), F l_{K}\left(X_{v}\right)$. This is done in Chapter 6. The case of points in intersecting flow-spaces $F l_{K}\left(X_{u}\right), F l_{K}\left(X_{v}\right)$ is handled in Section 6.1 where we primarily analyze the case of special intervals $\llbracket u, v \rrbracket \subset T$, i.e. when $F l_{K}\left(X_{u}\right) \cap X_{v} \neq \emptyset$. This covers Step 4 of our description of geodesics in $X$ and is quite technical. The main trick is to introduce a certain generalization of flow-spaces of vertex-spaces and appeal to a special (and easy) case of

Theorem 2.58 proven earlier, the quasiconvex amalgamation, when the tree $T$ contains a single edge (Corollary 2.62). Once the case of special intervals is done, we complete easily Step 5 of our description of geodesics by considering points in flow-spaces $F l_{K}\left(X_{J}\right)$ for subintervals $J \subset T$ represented as unions of three special subintervals: For the proof we use the quasiconvex amalgamation again. (A good example of such an interval $J$ is given by a semispecial interval $\llbracket u, v \rrbracket$, where the flow-spaces $F l_{K}\left(X_{u}\right), F l_{K}\left(X_{v}\right)$ have nonempty intersection in $X$.) Lastly, we conclude the 6 -step description of geodesics in $X$ by appealing to the horizontal subdivision of geodesic intervals $J$ in $T$, so that the consecutive subdivision vertices $u_{i}, u_{i+1}$ define pairwise uniformly cobounded flow-spaces $F l_{K}\left(X_{u_{i}}\right), F l_{K}\left(X_{u_{i+1}}\right)$ (their projections to the tree $T$ are disjoint), while each interval $\llbracket u_{i}, u_{i+1} \rrbracket$ between $u_{i}, u_{i+1}$ is a union of three special subintervals. This uniform coboundedness property allows us to reduce the problem of hyperbolicity of the flow-space $F l_{K}\left(X_{J}\right) \subset X$ to the pairwise cobounded quasiconvex chain-amalgamation of hyperbolic spaces which is, again a special and easy case of Theorem 2.58 proven earlier (Theorem 2.59). The combing paths $c(x, y)$ in $X$ are then defined as geodesics in flow-spaces $F l_{K}\left(X_{J}\right), x \in X_{u}, y \in X_{v}$, and $J=\llbracket u, v \rrbracket$. Lastly, we verify the slim combing property for these paths $c(x, y)$ by considering flow-spaces $F l_{K}\left(X_{S}\right)$ for geodesic tripods $S \subset T$ and appealing to Theorem 2.59 (or, more precisely, its consequence, Corollary 2.63) one last time.

In Chapter 7 we review the description of the combing paths $c(x, y)$ by putting together different steps of the descriptions scattered in the earlier parts of the book. We also prove an easy application of this description by giving a characterizations of geodesics $\alpha$ in vertex-spaces of $X$ which are quasigeodesics in $X$ itself, in terms of carpets bounded by subintervals in $\alpha$. Furthermore, assuming acylindricity, we give a simplified description of uniform quasigeodesics and quasigeodesic rays in $X$. We use this description to describe the ideal boundary of $X$ in terms of ideal boundaries of vertex spaces and of the tree $T$.

In Chapter 8 we apply our description of geodesics to prove Theorem 8.46, establishing existence of Cannon-Thurston maps for subtrees of spaces $\mathfrak{Y}$ in a hyperbolic tree of spaces $\mathfrak{X}$. The main technical result of the chapter is Theorem 8.19 which relates quasigeodesics $\phi$ in $X$ to quasigeodesics in $Y$ via a certain cut-and-replace procedure, replacing detour subpaths in $\phi$ by geodesics in vertex-spaces of $Y$. Along the way, we relate nearestpoint projections to flow-spaces $F l_{K}\left(X_{u}\right)$ taken in $X$ and in $Y$. We give a necessary and sufficient condition for points to have equal images under these Cannon-Thurston maps (Theorem 8.50). In particular, such points have to belong to the Gromov boundary of the same vertex-space of $\mathfrak{Y}$. In the following four sections of the chapter we discuss CannonThurston laminations for the inclusion maps $X_{v} \rightarrow X$ in more detail. In the last section of the chapter, we discuss group-theoretic applications of our results. In particular, we construct examples of non-Anosov undistorted surface subgroups of $\operatorname{PS} L(2, \mathbb{C}) \times P S L(2, \mathbb{C})$ consisting entirely of semisimple elements.

In Chapter 9 we consider trees of relatively hyperbolic spaces and, generalizing the results of Chapter 8, prove existence of Cannon-Thurston maps in this context and establish some properties of the associated Cannon-Thurston laminations.

There are many constants and functions used in the book. As a general rule, we label these using as the subscript the number of the theorem (or lemma, etc.) where these quantities are introduced.

Acknowledgements. During the work on this book the first author was partly supported by the NSF grant DMS-16-04241 and by a Simons Fellowship, grant number 391602.

## CHAPTER 1

## Preliminaries on metric geometry

### 1.1. Graphs and trees

Although we always work with unoriented metric graphs like Cayley graphs, we will also need oriented graphs, to describe graphs of groups. The following definition is taken from [Ser03]:

Definition 1.1. An oriented graph $\Gamma$ is a pair of sets $(V, E)$ together with two maps

$$
E \rightarrow V \times V, \quad e \mapsto(o(e), t(e))
$$

and

$$
E \rightarrow E, \quad e \mapsto \bar{e}
$$

such that $o(\bar{e})=t(e), t(\bar{e})=o(e)$ and $\overline{\bar{e}}=e$ for all $e \in E$.
We write $V(\Gamma)$ for $V$ and $E(\Gamma)$ for $E$. We refer to $V(\Gamma)$ as the set of vertices of $\Gamma$ and $E(\Gamma)$ as the set of edges of $\Gamma$. We will almost always conflate a graph $\Gamma$ with its underlying space, i.e. its geometric realization as a 1 -dimensional CW complex.

For an edge $e$ of a graph we refer to $o(e)$ as the origin and $t(e)$ as the terminus of $e$; the edge $\bar{e}$ is the same edge $e$ with opposite orientation. When $o(e)=v, t(e)=w$, we will use the notation $e=[v, w]$. While for general graphs this notation is ambiguous, for graphs which are trees (and this is the case we are mostly interested in), vertices $v, w$ uniquely determine the oriented edge $e$.

We shall denote by $|e|$ the edge $e$ of $\Gamma$ without any orientation, regarded as a subset of the underlying space of $\Gamma$. For each edge $e$ in a graph we define $\dot{e}$ to be $|e|$ with the end-points removed.

Given a subset $W \subset V$, we define the full subgraph of $\Gamma$ spanned by $W$ as the maximal subgraph in $\Gamma$ with the vertex-set $W$. The valence or degree of a vertex $v \in V$ is the cardinality of the set $o^{-1}(v) \subset E$ (equivalently, $t^{-1}(v) \subset E$ ).

If $\Lambda \subset \Gamma$ is a subgraph, then a vertex $v \in V(\Lambda)$ is a boundary vertex of $\Lambda$, if there is an edge $e=[v, w] \in V(\Gamma)$ such that $w \notin V(\Lambda)$. The edge $e$ is then called a boundary edge of $\Lambda$ in $\Gamma$. We will use this notion only when $\Lambda$ is a subtree of a tree $\Gamma$.

A graph-morphism, or a morphism of graphs $\phi: \Gamma \rightarrow \Gamma^{\prime}$ is a pair of maps $\phi_{V}: V(\Gamma) \rightarrow$ $V\left(\Gamma^{\prime}\right), \phi_{E}: E(\Gamma) \rightarrow E\left(\Gamma^{\prime}\right), v \mapsto v^{\prime}, e \mapsto e^{\prime}$ such that the following diagrams commute for all oriented edges $e=[v, w]$ :

where the horizontal arrows are the origin/tail maps.

A tree is a simply-connected graph.
We will use both the notation $u v$ and $\llbracket u, v \rrbracket$ for the (geodesic) segment, or an interval, in $\Gamma$ whose end-points are the vertices $u, v$. (Since we will be mostly working with graphs which are trees, this notation is unambiguous.) Given a segment $\llbracket u, v \rrbracket$ in a tree, we define $\rrbracket u, v \llbracket$ as the maximal subtree of $\llbracket u, v \rrbracket$ containing all the vertices of $\llbracket u, v \rrbracket$ except for $u$ and $v$. Similarly, we define subsegments $\rrbracket u, v \rrbracket$ and $\llbracket u, v \llbracket$.

Convention 1.2. We will regard intervals $\llbracket u, v \rrbracket$ in simplicial trees as ordered sets with $u$ the smallest element and $v$ the largest. Accordingly, we will talk about supremums and infimums of subsets of $\llbracket u, v \rrbracket$ and $\sup (\emptyset)=u, \inf (\emptyset)=v$.

A metric graph is a connected graph $\Gamma$, every edge $e$ of which is assigned a positive real number $\ell(e)$ (its length). The vertex-set of $\Gamma$ then has a natural pseudometric $d_{\ell}$, where the distance between vertices is defined to be the infimum of total lengths of edge-paths connecting these vertices. The metric $d_{\ell}$ extends to a pseudometric on the underlying space of $\Gamma$. Note, however, that the distance between the vertices of an edge $e$ of $\Gamma$ can be smaller than $\ell(e)$ even if the vertices are distinct. If $\ell: E(\Gamma) \rightarrow \mathbb{R}_{+}$takes only finitely many values, then $\left(\Gamma, d_{\ell}\right)$ is a complete geodesic metric space. If the function $\ell$ is bounded away from 0 , then $d_{\ell}$ is a metric, but, in general, metric graphs need not be complete nor geodesic and the pseudometric need not be a metric.

Example 1.3. Let $\Gamma$ be a graph with two vertices $v, w$ and edges $\left\{e_{i}\right\}_{i \in \mathbb{N}}$ all of which connect $v$ to $w$.

1. Take the function $\ell\left(e_{i}\right)=\frac{1}{i}$. Then $d_{\ell}(v, w)=0$. Hence, $d_{\ell}$ is not a metric in this example.
2. Take the function $\ell\left(e_{i}\right)=1+\frac{1}{i}$. Then $d_{\ell}$ is a metric but $\Gamma$ contains no geodesics between $v$ and $w$.

Example 1.4. Consider the graph $\Gamma$, which is the complete graph on the set $\left\{v_{1}, v_{2}, v_{3}\right\}$. Let $\ell\left(\left[v_{1}, v_{2}\right]\right)=\ell\left(\left[v_{2}, v_{3}\right]\right)=1, \ell\left(\left[v_{3}, v_{1}\right]\right)=3$. Then $d_{\ell}\left(v_{1}, v_{3}\right)$ is 2 rather than $3=$ $\ell\left(\left[v_{3}, v_{1}\right]\right)$.

Most of the time, unless stated otherwise, we will metrize connected graphs $\Gamma$ by declaring that every edge has unit length: The distance between vertices equals the minimal number of edges in an edge-path connecting these vertices. We refer to the resulting metric on $\Gamma$ as the graph-metric.

### 1.2. Coarse geometric concepts

1.2.1. Metric notions. For a subset $A$ of a topological space $X, \operatorname{cl}(A)$ will denote the closure of $A$ in $X$. By a path in a topological space $X$ we will always means a continuous map $I \rightarrow X$, where $I$ is an interval in $\mathbb{R}$. Given a path $c:[a, b] \rightarrow X$, we denote by ${ }_{c}$ the reverse path

$$
c(t)=c(a+b-t) .
$$

A path $c$ in a metric space $(X, d)$ is geodesic if it is an isometric embedding $I \rightarrow(X, d)$. We will frequently conflate paths and their images: Since we are primarily interested in geodesic and quasigeodesic paths, this conflation is mostly harmless. Accordingly, if $x, y$ are points in a path $c$ in $X$, then $c(x, y)$ will denote the subpath of $c$ between $x$ and $y$. This notation is, of course, slightly ambiguous since $c$ need not be injective, and a better notation would have been $\left.c\right|_{[s, t]}$ where $c(s)=x, c(y)=t$. However, in practice, it will be always clear what the subpath $c(x, y)$ is. We will use the notation $c_{1} \star c_{2}$ to denote the concatenation of two paths.

The length of a path $c: I \rightarrow(X, d)$, where $I=[a, b]$ is a finite closed interval in $\mathbb{R}$, is

$$
\text { length }(c)=\sup \sum_{i=1}^{n} d\left(c\left(t_{i}\right), c\left(t_{i+1}\right)\right)
$$

where the supremum is taken over all subdivisions of interval $I$ :

$$
t_{1}=a \leq t_{2} \leq \ldots \leq t_{n} \leq t_{n+1}=b
$$

A metric space $(X, d)$ is called rectifiably connected if every two points in it are connected by a path of finite length. A metric space $(X, d)$ is called a path-metric space and the metric $d$ a path-metric if for all points $x, y \in X$,

$$
d(x, y)=\inf _{c} \text { length }(c),
$$

where the infimum is taken over all paths in $X$ connecting $x$ and $y$. Examples of path-metric spaces are given by metric graphs (assuming, of course, that $d_{\ell}$ is a metric and not merely a pseudometric).

A metric space $(X, d)$ is called geodesic if for every two points $x, y \in X$ are connected by a geodesic path. We will use the notation $x y$, or $[x y]_{X}$, to denote a geodesic segment joining $x$ to $y$ in $X$. If $X$ is a simplicial tree and $u, v$ are vertices, then we will also use the notation $\llbracket u, v \rrbracket$ for this geodesic segment.

For $x, y, z \in X$ we shall denote by $\Delta x y z$ a geodesic triangle with vertices $x, y, z$ which is the union of three geodesic segments $x y \cup y z \cup z x$. Similarly, a geodesic quadrilateral in $X$ with vertices $x, y, z, w$, denoted $\square x y z w$, is the union of four geodesics

$$
x y \cup y z \cup z w \cup w x .
$$

For any rectifiably-connected subset $Y$ in a metric space $(X, d)$ we shall denote by $d_{Y}(\cdot, \cdot)$ the path-metric on $Y$ induced from $X$ : The distance between two points in $Y$ is the infimum of lengths of paths in $Y$ between these points, where the length of a path is computed using the restriction of the metric $d$.

For $R \geq 0$ and a subset $A \subset X$,

$$
N_{R}^{X}(A)=N_{R}(A):=\{x \in X: d(x, a) \leq R \text { for some } a \in A\}
$$

will denote the (closed) $R$-neighborhood of $A$ in $X$. A subset $A \subset X$ is said to be an $R$-net in $X$ if

$$
N_{R}(A)=X
$$

For subsets $Y, Z$ in a metric space $X, \operatorname{Hd}(Y, Z) \in[0, \infty]$ denotes the Hausdorff distance between $Y$ and $Z$ :

$$
\operatorname{Hd}(Y, Z)=\inf \left\{R: Y \subset N_{R}(Z), Z \subset N_{Z}(Y)\right\} .
$$

We will use the notation

$$
d(Y, Z)=\inf \{d(y, z): y \in Y, z \in Z\}
$$

for the minimal distance between $Y$ and $Z$. (Note that, unlike the Hausdorff distance, the minimal distance, in general, fails to satisfy the triangle inequality.) We will sometimes add the subscript $X$ in this notation to emphasize that the distances and neighborhoods are taken in $X$.

For two maps $f, g: X \rightarrow Y$ between metric spaces, we define the distance between $f, g$ as

$$
d(f, g)=\sup \{d(f(x), g(x)): x \in X\} .
$$

### 1.3. Group actions

Throughout the book, we will be only considering left group actions of groups on sets (the notation for such an action is $G \times X \rightarrow X$ or $G \curvearrowright X$ ). For instance, if $X$ is a group and $G$ is a subgroup of $X$ then the action of $G$ on $X$ via left-multiplication

$$
L_{g}(x)=g x
$$

is a left action of $G$ on $X$.
Given a $G$-action on a set $X$ and a point $x \in X$, one defines the orbit map for the action to be the map $o_{x}: G \rightarrow X$, by $o_{x}(g)=g x$. We will be primarily interested in isometric actions of discrete groups on metric spaces. Such an action is said to be metrically ${ }^{1}$ proper if for each bounded subset $B \subset X$ the subset

$$
\{g \in G: g B \cap B \neq \emptyset\}
$$

is finite. In other words, preimages of bounded subsets under orbit maps are finite. An isometric action is said to be cobounded if there exists a bounded subset $B \subset X$ such that $G B=X$. An action is said to be geometric if it is both proper and cobounded.

Suppose that we are given an isometric action $G \curvearrowright X$ and a subset $Y \subset X$. The stabilizer of $Y$ in $G$, denoted $G_{Y}$, is the subgroup of $G$ consisting of elements preserving $Y$ set-wise.

Definition 1.5. One says that the $G$-orbit $G Y$ of $Y$ is locally finite if for each $x \in X$ and $r \in \mathbb{R}_{+}$, there exist a finite subset $\left\{g_{1}, \ldots, g_{n}\right\} \subset G$ such that

$$
g Y \cap B(x, r) \neq \emptyset \Rightarrow g \in g_{i} G_{Y}
$$

for some $i=1, \ldots, n$.
In order to see that this condition is natural, observe that for $h \in G_{Y}$,

$$
g Y \cap B(x, r) \neq \emptyset \Longleftrightarrow g h Y \cap B(x, r) \neq \emptyset
$$

Lemma 1.6. Suppose that $X$ is a finitely-generated group equipped with the wordmetric and $Y<X$ is a subgroup. Then for each $G<X$, we have $G_{Y}=G \cap Y$ and the $G$-orbit $G Y$ is locally finite.

Proof. It suffices to prove the claim with $x=1$. Since the ball $B(1, r)$ is finite, there exist a finite set of pairs $\left(g_{i}, y_{i}\right), i=1, \ldots, n, g_{i} \in G, y_{i} \in Y$, such that whenever $y \in Y, g \in G$ satisfy $d_{X}(g y, 1) \leq r$, we have $g y=g_{i} y_{i}$ for some $i$. Then

$$
h=g_{i}^{-1} g=y_{i} y^{-1} \in G \cap Y=G_{Y}
$$

and, hence, $g=g_{i} h$, i.e. $g \in g_{i} H$, as required.
Corollary 1.7. Suppose that $X$ is a geodesic metric space, $G^{\prime} \curvearrowright X$ is a geometric action, $Y \subset X$ is a nonempty subspace whose $G^{\prime}$-stabilizer $G_{Y}^{\prime}$ also acts geometrically on $Y$. Then for each subgroup $G<G^{\prime}$, the $G$-orbit $G Y$ is locally finite.

[^1]
### 1.4. Length structures and spaces

Let $X$ be a topological space. A length structure on $X$ is a collection $\mathcal{P}$ of admissible paths (defined on closed intervals in $\mathbb{R}$ ) in $X$, together with a map

$$
\ell: \mathcal{P} \rightarrow \mathbb{R}_{+}
$$

(called a length function) satisfying the following axioms:

1. $\mathcal{P}$ is closed under restrictions: The restriction of a path $c \in \mathcal{P}$ to a subinterval again belongs to $\mathcal{P}$.
2. $\mathcal{P}$ is closed under concatenations.
3. $\mathcal{P}$ is closed under linear reparameterizations.
4. $\ell\left(c_{1} \star c_{2}\right)=\ell\left(c_{1}\right)+\ell\left(c_{2}\right)$.
5. $\ell$ is invariant under linear reparameterizations.
6. For each $c:[A, B] \rightarrow X, c \in \mathcal{P}$, the length $\ell\left(\left.c\right|_{[a, b]}\right)$ depends continuously on $a$.
7. The length function $\ell$ is consistent with the topology of $X$ in the sense that for each $x \in X$ and each neighborhood $U$ of $X$

$$
\inf _{c \in \mathcal{P}(x, X-U)} \ell(c)>0
$$

where $\mathcal{P}(x, X-U)$ consists of all paths $c \in \mathcal{P}, c:[a, b] \rightarrow X, c(a)=x, c(b) \in X-U$.
8. For each pair of points $x, y \in X$ the subset $\mathcal{P}_{x, y}$ consisting of paths $c \in \mathcal{P}$ connecting $x$ to $y$ is nonempty.

A length space is a topological space equipped with a length structure. Each length space $(X, \mathcal{P}, \ell)$ has a canonical metric $d=d_{\ell}$ defined by

$$
d(x, y)=\inf _{c \in \mathcal{P}_{x, y}} \ell(c)
$$

The topology defined by this metric is finer than the one of $X$; the metric $d_{\ell}$ is a path-metric (see Proposition 2.4.1 in [BBI01]).

### 1.5. Coarse Lipschitz maps and quasiisometries

Below, we let $X, Y, Z$ denote metric spaces and let $L \geq 1, \epsilon \geq 0$.
(1) Suppose $Z$ is a set. A map $f: Z \rightarrow Y$ is said to be $D$-coarsely surjective if $Y=N_{D}(f(Z))$, i.e. $f(Z)$ is a $D$-net in $X$.
(2) Suppose $\left\{Z_{\alpha}\right\}$ and $\left\{Y_{\alpha}\right\}$ are, respectively, a family of sets and a family of metric spaces. A family of maps $f_{\alpha}: Z_{\alpha} \rightarrow Y_{\alpha}$ is said to be uniformly coarsely surjective if there is a constant $D \geq 0$, such that for all $\alpha, Y_{\alpha}=N_{D}\left(f_{\alpha}\left(Z_{\alpha}\right)\right)$.
(3) A map $f: X \rightarrow Y$ is said to be ( $L, \epsilon$ )-coarsely Lipschitz (or coarse Lipschitz) if $\forall x_{1}, x_{2} \in X$ we have

$$
d_{Y}\left(f\left(x_{1}\right), f\left(x_{2}\right)\right) \leq L d_{X}\left(x_{1}, x_{2}\right)+\epsilon
$$

A map $f$ is coarsely Lipschitz if it is $(L, \epsilon)$-coarsely Lipschitz for some $L \geq 1, \epsilon \geq$ 0 . When $L=\epsilon$, we say that $f$ is L-coarsely Lipschitz.
(4) Let $\eta: S \subset \mathbb{R}_{+} \rightarrow \mathbb{R}_{+}$be a function. A map of metric spaces $f: X \rightarrow Y$ is called ( $\eta, L$ )-proper if $f$ is $L$-coarsely Lipschitz and $d\left(f\left(x_{1}\right), f\left(x_{2}\right)\right) \leq R$ implies that $d\left(x_{1}, x_{2}\right) \leq \eta(R)$. The function $\eta$ is a distortion function of $f$. We will frequently suppress the coarse Lipschitz constant $L$ (it will be often equal to 1 ) and simply say that $f$ is $\eta$-proper. For instance, if $Y \subset X$ is a rectifiably connected subset of a path-metric space $\left(X, d_{X}\right)$, we say that $Y$ is $\eta$-properly embedded in $X$ if the inclusion map $\left(Y, d_{Y}\right) \rightarrow\left(X, d_{X}\right)$ is $\eta$-proper.
(5) Similarly, suppose that $f_{\alpha}:\left(X_{\alpha}, d_{X_{\alpha}}\right) \rightarrow\left(Y_{\alpha}, d_{Y_{\alpha}}\right)$, is a family of maps between metric spaces. If these maps are $(\eta, L)$-proper for some $\eta$ and $L$, then we will say that this family of maps is uniformly proper.
(6) A map $f: X \rightarrow Y$ is said to be an ( $L, \epsilon$ )-quasiisometric embedding if $\forall x_{1}, x_{2} \in X$ one has

$$
\frac{1}{L} d_{X}\left(x_{1}, x_{2}\right)-\epsilon \leq d_{Y}\left(f\left(x_{1}\right), f\left(x_{2}\right)\right) \leq L d_{X}\left(x_{1}, x_{2}\right)+\epsilon
$$

(7) A map $f: X \rightarrow Y$ will be simply referred to as a quasiisometric embedding if it is an $(L, \epsilon)$-quasiisometric embedding for some $L \geq 1$ and $\epsilon \geq 0$.
(8) An ( $L, L$ )-quasiisometric embedding will be referred to as an L-quasiisometric embedding.
(9) A map $f: X \rightarrow Y$ is said to be a $(L, \epsilon)$-quasiisometry if it is an $(L, \epsilon)$-quasiisometric embedding, which is also $\epsilon$-coarsely surjective. If $L=\epsilon$ then we will refer to such $f$ as an L-quasiisometry.
(10) We will use the abbreviation qi for the word quasiisometric.
(11) An $(L, \epsilon)$-quasigeodesic (resp. an L-quasigeodesic) in a metric space $X$ is a $(L, \epsilon)$-quasiisometric embedding (resp. a $L$-quasiisometric embedding) $\gamma: I \rightarrow$ $X$, where $I \subseteq \mathbb{R}$ is an interval.
(12) Given two maps $f: X \rightarrow Y$ and $g: Y \rightarrow X$, we say that $g$ is an $\epsilon$-coarse left inverse of $f$ if $d\left(f \circ g, \mathrm{id}_{Y}\right) \leq \epsilon$. Similarly one defines an $\epsilon$-coarse right inverse. If $g$ is both $\epsilon$-coarse left and right inverse then it is called an $\epsilon$-coarse inverse of $f$.
(13) If $A \subset X$ and $i: A \rightarrow X$ is the inclusion map, then an $(L, \epsilon)$-coarse retraction of $X$ to $A$ is a $(L, \epsilon)$-coarsely Lipschitz map $g: X \rightarrow A$ such that $\left.g\right|_{A}=\mathrm{id}_{A}$.

Remark 1.8. More generally, one can define an $(L, \epsilon)$-coarse retraction by requiring that

$$
d\left(\mathrm{id}_{A}, g \circ i\right) \leq \epsilon
$$

However, in the book we only use the more restrictive definition.
Example 1.9. 1. Let $G, H$ be finitely-generated groups equipped with word metrics and $\phi: G \rightarrow H$ is a homomorphism. Then $\phi$ is a coarse Lipschitz map. If $\phi$ has finite kernel, then it is also uniformly proper.
2. Suppose that $G$ is a finitely-generated (discrete) group, $G \curvearrowright X$ is a proper isometric action on a metric space, then for each $x \in X$, the orbit map $o_{x}: G \rightarrow X$ is uniformly proper.

Definition 1.10. One says that a finitely-generated subgroup $G$ of a finitely generated group $H$ has distortion at most $\eta$ if the inclusion map $G \rightarrow H$ is $\eta$-proper (when $G, H$ are equipped with word metrics as above).

Thus, a subgroup $G$ of a group $H$ is at most linearly distorted if and only if it is qi embedded in $H$. In this case, one says that $G$ is undistorted in $H$. One can make the notion of distortion independent of a generating set by working with a suitable equivalence relation on distortion functions. For instance, one can talk about polynomial distortion, exponential distortion, etc. We refer the reader to [DK18] for further details.

We next discuss quasiisometries and qi embeddings of metric spaces. The following lemma is a direct calculation which we omit:

Lemma 1.11. 1. Suppose that $f_{1}: X_{1} \rightarrow X_{2}$ and $f_{2}: X_{2} \rightarrow X_{3}$ are, respectively, $\left(L_{1}, \epsilon_{1}\right)$ and $\left(L_{2}, \epsilon_{2}\right)$-coarse Lipschitz. Then their composition is $\left(L_{1} L_{2}, L_{2} \epsilon_{1}+\epsilon_{2}\right)$-coarse Lipschitz.
2. Suppose that $f_{1}: X_{1} \rightarrow X_{2}$ and $f_{2}: X_{2} \rightarrow X_{3}$ are, respectively, $\left(L_{1}, \epsilon_{1}\right)$ and $\left(L_{2}, \epsilon_{2}\right)$-qi embeddings. Then their composition is an $\left(L_{1} L_{2}, L_{2} \epsilon_{1}+\epsilon_{2}\right)$-qi embedding.

Lemma 1.12. Let $f: X \rightarrow Y$ be an L-quasiisometry. Then $f$ admits a coarse $3 L^{2}$ inverse which is a $3 L^{2}$-quasiisometry $Y \rightarrow X$.

Proof. For $y \in Y$ define $g(y)=x$ such that $d(y, f(x)) \leq L$. Then

$$
L^{-1} d\left(y, y^{\prime}\right)-3 \leq d\left(g(y), g\left(y^{\prime}\right)\right) \leq L d\left(y, y^{\prime}\right)+3 L^{2}
$$

and

$$
d(f \circ g(y), y) \leq L, d(g \circ f(x), x) \leq 2 L^{2}
$$

Lemma 1.13. Let $f_{i}: X_{i} \rightarrow Y$ be $k$-qi embeddings such that

$$
\operatorname{Hd}\left(\operatorname{Im}\left(f_{1}\right), \operatorname{Im}\left(f_{2}\right)\right) \leq r
$$

## Define a map

$$
g: X_{1} \rightarrow X_{2}
$$

sending $x_{1} \in X_{1}$ to a point $x_{2} \in X_{2}$ such that $d\left(f_{1}\left(x_{1}\right), f_{2}\left(x_{2}\right)\right) \leq r$. Then $g$ is a $K=$ $K_{1.13}(r, k)$-quasiisometry.

Proof. Let $x_{1}, y_{1} \in X_{1}$. Then

$$
-k+\frac{1}{k} d_{X_{1}}\left(x_{1}, y_{1}\right) \leq d_{Y}\left(f_{1}\left(x_{1}\right), f_{1}\left(y_{1}\right)\right) \leq k+k d_{X_{1}}\left(x_{1}, y_{1}\right) .
$$

Setting $x_{2}:=g\left(x_{1}\right)$ and $y_{2}:=g\left(y_{1}\right) \in X_{2}$, we obtain

$$
d_{Y}\left(f_{1}\left(x_{1}\right), f_{2}\left(x_{2}\right)\right) \leq r \quad \text { and } \quad d_{Y}\left(f_{1}\left(y_{1}\right), f_{2}\left(y_{2}\right)\right) \leq r .
$$

It follows that

$$
\left|d_{Y}\left(f_{1}\left(x_{1}\right), f_{1}\left(y_{1}\right)\right)-d_{Y}\left(f_{2}\left(x_{2}\right), f_{2}\left(y_{2}\right)\right)\right| \leq d_{Y}\left(f_{1}\left(x_{1}\right), f_{2}\left(x_{2}\right)\right)+d_{Y}\left(f_{1}\left(y_{1}\right), f_{2}\left(y_{2}\right)\right) \leq 2 r
$$

Hence, we get

$$
-k-2 r+\frac{1}{k} d_{X_{1}}\left(x_{1}, y_{1}\right) \leq d_{Y}\left(f_{2}\left(x_{2}\right), f_{2}\left(y_{2}\right)\right) \leq 2 r+k+k d_{X_{1}}\left(x_{1}, y_{1}\right)
$$

Since $f_{2}$ is a $k$-qi embedding, we have

$$
-k+\frac{1}{k} d_{X_{2}}\left(x_{2}, y_{2}\right) \leq d_{Y}\left(f_{2}\left(x_{2}\right), f_{2}\left(y_{2}\right)\right) \leq k+k d_{X_{2}}\left(x_{2}, y_{2}\right)
$$

Using these two sets of inequalities we obtain

$$
-\frac{2 r+2 k}{k}+\frac{1}{k^{2}} d_{X_{1}}\left(x_{1}, y_{1}\right) \leq d_{X_{2}}\left(x_{2}, y_{2}\right) \leq 2 k^{2}+2 r k+k^{2} d_{X_{1}}\left(x_{1}, y_{1}\right)
$$

Since $g\left(x_{1}\right)=x_{2}, g\left(y_{1}\right)=y_{2}$, it follows that $g$ is a ( $2 r k+2 k^{2}$ )-qi embedding.
Also, given any $x_{2}^{\prime} \in X_{2}$, there is an $x_{1}^{\prime} \in X_{1}$ such that $d_{Y}\left(f_{1}\left(x_{1}^{\prime}\right), f_{2}\left(x_{2}^{\prime}\right)\right) \leq r$. If $x_{2}^{\prime \prime}=g\left(x_{1}^{\prime}\right)$. Then $d_{Y}\left(f_{1}\left(x_{1}^{\prime}\right), f_{2}\left(x_{2}^{\prime \prime}\right)\right) \leq r$. Hence,

$$
d_{Y}\left(f_{2}\left(x_{2}^{\prime \prime}\right), f_{2}\left(x_{2}^{\prime}\right)\right) \leq d_{Y}\left(f_{1}\left(x_{1}^{\prime}\right), f_{2}\left(x_{2}^{\prime}\right)\right)+d_{Y}\left(f_{1}\left(x_{1}^{\prime}\right), f_{2}\left(x_{2}^{\prime \prime}\right)\right) \leq 2 r
$$

Since $f_{2}$ is a $k$-qi embedding it follows that $d_{X_{2}}\left(x_{2}^{\prime}, x_{2}^{\prime \prime}\right) \leq 2 r k+k^{2}<2 r k+2 k^{2}$. Hence $g$ is a $K=\left(2 r k+2 k^{2}\right)$-quasiisometry.

Lemma 1.14. Suppose $f: X \rightarrow Y$ and $g: X \rightarrow Y$ are $(L, \epsilon)$-coarsely Lipschitz maps between metric spaces such that $d\left(\mathrm{id}_{X}, g \circ f\right) \leq R$ and $d\left(\mathrm{id}_{Y}, f \circ g\right) \leq R$. Then $f$ as well as $g$ is an $(L, \epsilon+2 R)$-quasiisometry.

Proof. The proof of this lemma follows easily from definitions. We refer to [MS09, Lemma 1.1] for details.

The next lemma follows immediately from definitions:
Lemma 1.15. Suppose that $\left(Y, d_{Y}\right)$ is a metric space, $X \subset Y$ is a subset equipped with a metric $d_{X}$ such that the inclusion map $\left(X, d_{X}\right) \rightarrow\left(Y, d_{Y}\right)$ is L-coarse Lipschitz and admits an L-coarse Lipschitz retraction $\left(Y, d_{Y}\right) \rightarrow\left(X, d_{X}\right)$. Then the inclusion map $X \rightarrow Y$ is an L-qi embedding.

Remark 1.16. 1. Few categorical remarks are in order at this point. It is natural to consider the coarse category $\mathcal{C}$, where objects are metric spaces and morphisms are equivalence classes of coarse Lipschitz maps (more generally, correspondences). Here two maps are declared to be equivalent if they are bounded distance apart. Isomorphisms in this setting are precisely quasiisometries of metric spaces. Monomorphisms or monic morphisms in this category are uniformly left-cancellative morphisms, meaning that $f$ : $X \rightarrow Y$ is monic if for each pair of $(L, \epsilon)$-coarse Lipschitz maps $g_{i}: Z \rightarrow X, i=1,2$, if $d\left(f \circ g_{1}, f \circ g_{2}\right) \leq D$ then $d\left(g_{1}, g_{2}\right) \leq C(L, \epsilon, D)$. (Note the need for the uniform control on distances!) It is easy to verify that monic morphisms are precisely (equivalences classes of) uniformly proper maps; hence, monomorphisms are more general than qi embeddings. Epimorphisms are precisely the coarsely surjective maps. Most important examples of these, besides quasiisometries, are given by coarse retractions to subsets of metric spaces. The coarse retractions frequently used in the book are Mitra's projections (in the setting of subtrees of hyperbolic spaces) and nearest-point projections to quasiconvex subsets of hyperbolic spaces.
2. An even more general formalism of coarse structures is developed by John Roe in [Roe03].
3. The above categorical notions, unfortunately, are not quite satisfactory for our purpose, since most of the time we have to keep track of various quantities such as distances between equivalent maps, coarse Lipschitz constants and distortion functions. For instance, when defining a graph (even a tree) of metric spaces, it is not quite enough to say that this is a functor from a graph (regarded as a category) to the category $C$, sending origin/terminus maps to monic morphisms of metric spaces: We will need uniform control of coarse Lipschitz constants and distortion functions. For a tree of hyperbolic spaces, we will need even more control, bounding hyperbolicity constants. For this reason, we will adopt a more pedestrian (and traditional) approach, and mostly refrain from using the categorical language.

Lemma 1.17. Let $Y$ be a path-metric space, $X \subset Y$ is an $\eta$-properly embedded subset equipped with the induced path-metric such that $X$ is an $R$-net in $Y$. Then the inclusion map $\iota: X \rightarrow Y$ is an L-qi embedding with $L=\eta(2 R+1)$.

Proof. Take $x, x^{\prime} \in X$, let $c=c_{\epsilon}: I=[0, T] \rightarrow Y$ be an arc-length parameterized path in $Y$ connecting $x$ to $x^{\prime}$ whose length $T$ is $\leq d\left(x, x^{\prime}\right)+\epsilon$. Subdivide the interval $I$ into $n+1$ subintervals $\left[t_{i}, t_{i+1}\right], t_{0}=0$, such that $t_{i+1}-t_{i}=1$ except for $i=n, 0 \leq r=t_{n+1}-t_{n}<1$. Let $P: Y \rightarrow X$ be a nearest-point projection. We apply $P$ to the sequence of points $y_{i}=c\left(t_{i}\right)$ and get a sequence $x_{0}=x, x_{1}=P\left(y_{1}\right), \ldots, x_{n}=p\left(y_{n}\right), x_{n+1}=x^{\prime}$ such that

$$
d_{Y}\left(x_{i}, x_{i+1}\right) \leq 2 R+1, i=0, \ldots, n
$$

Hence, $d_{X}\left(x, x^{\prime}\right) \leq L(n+1), L=\eta(2 R+1)$. Therefore,

$$
d_{X}\left(x, x^{\prime}\right) \leq L\left(d_{Y}\left(x, x^{\prime}\right)+1\right)
$$

i.e. $\iota$ is an $L$-qi embedding.

Remark 1.18. Of course, in this situation, the map $\iota$ is also a quasiisometry $X \rightarrow Y$.
Lemma 1.19. Given a function $\eta: \mathbb{R}_{+} \rightarrow \mathbb{R}_{+}$and $R \geq 0$, there is a constant $K=$ $K_{1.19}(\eta, R)$ such that the following holds.

Suppose $Z$ is a metric space and $Z_{1}, Z_{2}$ are two rectifiably-connected subsets in $Z$ such that, both $Z_{1}$ and $Z_{2}$ are $\eta$-properly embedded in $Z$. Assume $\operatorname{Hd}\left(Z_{1}, Z_{2}\right) \leq R$ and suppose $f: Z_{1} \rightarrow Z_{2}$ is any map that such that $d_{Z}(z, f(z)) \leq R$ for all $z \in Z_{1}$. Then $f$ is a K-quasiisometry.

Proof. Since $\operatorname{Hd}\left(Z_{1}, Z_{2}\right) \leq R$ clearly there is a similar map $g: Z_{2} \rightarrow Z_{1}$. We note that $d_{Z}(z, g \circ f(z)) \leq 2 R$ for all $z \in Z_{1}$. Hence, $d_{Z_{1}}(z, g \circ f(z)) \leq \eta(2 R)$ for all $z \in Z_{1}$, since $Z_{1}$ is $\eta$-properly embedded in $Z$, i.e. $d\left(\mathrm{id}_{Z_{1}}, g \circ f\right) \leq \eta(2 R)$. Similarly, $d\left(\mathrm{id}_{Z_{2}}, f \circ g\right) \leq \eta(2 R)$.

We claim that $f, g$ are coarsely Lipschitz. Since the proofs are similar we shall show this only for $f$. Since $\left(Z_{1}, d_{Z_{1}}\right)$ is a path-metric space it is enough to show that if $z, w \in$ $Z_{1}$ and $d_{Z_{1}}(z, w) \leq 1$, then $d_{Z_{2}}(f(z), f(w))$ is bounded by a constant independent of $z, w$. However,

$$
d_{Z}(f(z), f(w)) \leq d_{Z}(z, f(z))+d_{Z}(w, f(w))+d_{Z}(z, w) \leq 1+2 R
$$

Hence $d_{Z_{2}}(f(z), f(w)) \leq \eta(2 R+1)$, since $Z_{2}$ is $\eta$-properly embedded in $Z$. Now the claim follows from Lemma 1.14.

Lemma 1.20. Given $D \geq 0, k \geq 1$ and $\eta: \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}_{\geq 0}$, there is $K=K_{1.20}(D, k, \eta)$ with the following property:

Suppose $X$ is a metric space and $x, y \in X$ are arbitrary points. Suppose also that $c$ is a 1-Lipschitz path in a metric space $X$ joining points $x, y$ is $\eta$-properly embedded in $X$ and there is a continuous arc-length parametrized $k$-quasigeodesic $c_{1}$ joining $x, y$ in $X$ such that $\operatorname{Hd}\left(c, c_{1}\right) \leq D$. Then $c$ is a $K$-quasigeodesic.

Proof. Let $c:[0, l] \rightarrow X, c_{1}:\left[0, l_{1}\right] \rightarrow X$ be the given paths. Since $c$ is 1 -Lipschitz, for all $s, s^{\prime} \in[0, l]$ we have $d_{X}\left(c(s), c\left(s^{\prime}\right)\right) \leq\left|s-s^{\prime}\right|$. On the other hand, there are points $t, t^{\prime} \in\left[0, l_{1}\right]$ such that $d_{X}\left(c_{1}(t), c(s)\right) \leq D, d_{X}\left(c_{1}\left(t^{\prime}\right), c\left(s^{\prime}\right)\right) \leq D$. Let

$$
t_{1}=t \leq t_{2} \leq \cdots \leq t_{n} \leq t_{n+1}=t^{\prime}
$$

be points of $\left[0, l_{1}\right]$ such that $t_{i+1}-t_{i}=1,1 \leq i \leq n-1$, and $t_{n+1}-t_{n} \leq 1$. Then there are points

$$
s_{1}=s, s_{2}, \cdots, s_{n}, s_{n+1}=s^{\prime}
$$

in $[0, l]$ such that $d_{X}\left(c_{1}\left(t_{i}\right), c\left(s_{i}\right)\right) \leq D$. It follows that

$$
d_{X}\left(c\left(s_{i}\right), c\left(s_{i+1}\right)\right) \leq 2 D+d_{X}\left(c_{1}\left(t_{i}\right), c_{1}\left(t_{i+1}\right)\right) \leq 2 D+2 k, \quad 1 \leq i \leq n
$$

Hence, $\left|s_{i}-s_{i+1}\right| \leq \eta(2 D+2 k)$ and, therefore,

$$
\left|s-s^{\prime}\right| \leq n \eta(2 D+2 k) \leq \eta(2 D+2 k)+\eta(2 D+2 k)\left|t-t^{\prime}\right|
$$

However,

$$
\left|t-t^{\prime}\right| \leq k^{2}+k d_{X}\left(c_{1}(t), c_{1}\left(t^{\prime}\right)\right) \leq k^{2}+2 D k+k d_{X}\left(c(s), c\left(s^{\prime}\right)\right)
$$

It follows that

$$
-\frac{1+k^{2}+2 D k}{k}+\frac{1}{\max \{1, k \eta(2 D+2 k)\}}|s-t| \leq d_{X}(c(s), c(t)) \leq|s-t|
$$

Thus, we may take $K=\max \left\{1, \eta(2 D+1), \frac{1+k^{2}+2 D k}{k}\right\}$.

The next lemma follows immediately from the definition of a uniformly proper embedding:

Lemma 1.21. Suppose that $\left(X, d_{X}\right)$ is a path-metric space, $Y \subset X$ is rectifiably connected and $\eta$-properly embedded in $X$, i.e. the inclusion map $\left(Y, d_{Y}\right) \rightarrow\left(X, d_{X}\right)$ is $\eta$-proper. Then for every subset $Z \subset Y$ and $R \geq 0$ we have

$$
N_{R}^{Y}(Z) \subset N_{R}^{X}(Z) \subset N_{\eta(R)}^{Y}(Z)
$$

Here the R-neighborhood $N_{R}^{Y}$ in $Y$ is taken with respect to the induced path-metric $d_{Y}$.
In the following three lemmas, $I=[a, b], I^{\prime}=\left[a^{\prime}, b^{\prime}\right]$ denote nondegenerate intervals in $\mathbb{R}$ (equipped with the standard metric).

Lemma 1.22 (Lipschitz approximation). Let $f: I \rightarrow I^{\prime}$ be a coarse (L, $\epsilon$ )-Lipschitz map. Then $f$ is within distance $\leq 2(L+\epsilon)$ from a piecewise-linear $2(L+\epsilon)$-Lipschitz map $g: I \rightarrow I^{\prime}$.

Proof. 1. First, assume that $b-a \geq 1$. We then subdivide the interval $I$ into subintervals

$$
\left[a_{0}, a_{1}\right]=\left[a, a_{1}\right],\left[a_{1}, a_{2}\right], \ldots,\left[a_{n}, b\right]=\left[a_{n}, a_{n+1}\right]
$$

of length at least $1 / 2$ and at most 1 . We replace the restriction of $f$ to each subinterval $I_{i}=\left[a_{i}, a_{i+1}\right]$ with a linear function $g_{i}$ such that $g_{i}\left(a_{i}\right)=f\left(a_{i}\right), g_{i}\left(a_{i+1}\right)=f\left(a_{i+1}\right)$. Since

$$
\begin{equation*}
\left|f\left(a_{i}\right)-f\left(a_{i+1}\right)\right|=\left|g_{i}\left(a_{i}\right)-g_{i}\left(a_{i+1}\right)\right| \leq L\left|a_{i}-a_{i+1}\right|+\epsilon \leq L+\epsilon, \tag{1.1}
\end{equation*}
$$

it is easy to see that

$$
d\left(\left.f\right|_{I_{i}}, g_{i}\right) \leq 2(L+\epsilon)
$$

Combining the linear functions $g_{i}$ we obtain a piecewise-linear function $g: I \rightarrow I^{\prime}$ such that $d(f, g) \leq 2(L+\epsilon)$. Since $a_{i+1}-a_{i} \geq 1 / 2$, the inequality (1.1) implies that the slope of each $g_{i}$ is at most $2(L+\epsilon)$. Hence, $g$ is $2(L+\epsilon)$-Lipschitz.
2. Suppose that $b-a<1$. Then we let $g$ be the constant function, equal $f(b)$. Since $|f(s)-f(t)| \leq L+\epsilon$ for all $s, t \in I, d(f, g) \leq L+\epsilon$.

Lemma 1.23 (Coarse monotonicity of quasiisometries). Set $D:=L(5 \epsilon+4 L)$. Suppose that $f: I \rightarrow I^{\prime}$ is an $(L, \epsilon)$-qi embedding. Then $f$ is coarsely monotonic in the sense that if $r<s<t$ are in I and $\min (s-r, t-s)>D$ then $f(s)$ is between $f(r)$ and $f(t)$.

Proof. Let $g$ be the Lipschitz approximation of $f$ as in Lemma 1.22. Since $f$ is an $(L, \epsilon)$-qi embedding and $d(f, g) \leq 2(L+\epsilon)$, we conclude that $g$ satisfies

$$
L^{-1}\left|t-t^{\prime}\right|-(5 \epsilon+4 L) \leq\left|g(t)-g\left(t^{\prime}\right)\right|
$$

for all $t, t^{\prime} \in I$. Suppose that, say,

$$
f(s)>\max (f(r), f(t))
$$

Then

$$
\min (f(s)-f(r), f(s)-f(t)) \geq L^{-1} D-\epsilon
$$

Once again since $d(f, g) \leq 2(L+\epsilon)$ we see that

$$
\min (g(s)-g(r), g(s)-g(t)) \geq D^{\prime}=L^{-1} D-(5 \epsilon+4 L)
$$

For concreteness, assume that $g(r) \leq g(t)$. By the Intermediate Value Theorem applied to the function $g$ (restricted to the interval $[r, s]$ ) there exists $t^{\prime} \in[r, s]$ such that $g\left(t^{\prime}\right)=g(t)$. We have $t-t^{\prime} \geq t-s>D$. Thus,

$$
L^{-1} D-(5 \epsilon+4 L)<L^{-1}\left|t-t^{\prime}\right|-(5 \epsilon+4 L) \leq 0 \Rightarrow D<L(5 \epsilon+4 L)
$$

which is a contradiction. If $f(s)<\min (f(r), f(t))$ then one can apply the same proof to the function $t \mapsto-f(t)$ to arrive at a contradiction.

Lemma 1.24 (Approximating quasiisometries by homeomorphisms). Let $I=[a, b]$, $I^{\prime}=\left[a^{\prime}, b^{\prime}\right]$ be nondegenerate intervals in $\mathbb{R}$ (equipped with the standard metric). Suppose that $f: I \rightarrow I^{\prime}$ is a $k$-quasiisometry sending $a$ to $a^{\prime}$ and $b$ to $b^{\prime}$. Then there exists $a$ (piecewise-linear) homeomorphism $\tilde{f}: I \rightarrow I^{\prime}$ within distance $D_{1.24}=D_{1.24}(k)$ from $f$ which is also a $k_{1.24}(k)$-quasiisometry.

Proof. The proof is similar to that of Lemma 1.22. Set $L=\epsilon=k$.

1. Suppose first that $b-a \geq 2 D$, where $D=L(5 \epsilon+4 L)=9 k^{2}$ (as in Lemma 1.23). We subdivide the interval $I=[a, b]$ into subintervals

$$
\left[a_{0}, a_{1}\right]=\left[a, a_{1}\right],\left[a_{1}, a_{2}\right], \ldots,\left[a_{n}, a_{n+1}\right]=\left[a_{n}, b\right],
$$

each of length greater than $D$ and at most $2 D$. According to Lemma 1.23, $f$ restricted to the subset

$$
J=\left\{a_{0}, a_{1}, \ldots, a_{n}, a_{n+1}\right\}
$$

is strictly monotonic. We then let $\tilde{f}=g: I \rightarrow I^{\prime}$ be the piecewise-linear function equal to $f$ on $J$ and linear on the complementary intervals. In particular,

$$
f(a)=a^{\prime}=g(a), \quad f(b)=b^{\prime}=g(b) .
$$

In view of monotonicity of $\left.f\right|_{J}$, the function $g$ is also (strictly) monotonic, hence, a homeomorphism. For $s, t \in\left[a_{i}, a_{i+1}\right]$ we have

$$
|f(s)-f(t)| \leq 2 D L+\epsilon=18 k^{3}+k
$$

Therefore, for all $t \in\left[a_{i}, a_{i+1}\right]$ we have

$$
\begin{gathered}
|f(t)-g(t)| \leq\left|f(t)-f\left(a_{i}\right)\right|+\left|f\left(a_{i}\right)-g(t)\right| \leq \\
\left|f(t)-f\left(a_{i}\right)\right|+\left|f\left(a_{i}\right)-f\left(a_{i+1}\right)\right| \leq 2\left(18 k^{3}+k\right)
\end{gathered}
$$

since $f\left(a_{i}\right)=g\left(a_{i}\right), f\left(a_{i+1}\right)=g\left(a_{i+1}\right)$ and $g$ is monotonic.
2. Suppose that $b-a \leq 2 D$. We then let $g=\tilde{f}$ be the linear function equal to $f$ on $\{a, b\} ; g(a)=a^{\prime}<g(b)=b^{\prime}$. As in Case $1, d(f, g) \leq 36 k^{3}+2 k$. Hence we can choose $D_{1.24}=36 k^{3}+2 k$. Since $f$ is a $k$-quasiisometry it follows that $\tilde{f}$ is a $k_{1.24}(k)=\left(k+D_{1.24}\right)-$ quasiisometry.

Defintition 1.25. Two subsets $Y, Z$ of a metric space $X$ are said to be $C$-Lipschitz cobounded if there exist $(L, \epsilon)$-coarse Lipschitz retractions $X \rightarrow Z, X \rightarrow Y$ whose restrictions

$$
r_{Y, Z}: Y \rightarrow Z, \quad r_{Z, Y}: Z \rightarrow Y
$$

satisfy:

1. $r_{Y, Z}(Y)$ and $r_{Z, Y}(Z)$ have diameters $D_{Y}, D_{Z}$.
2. $\max \left(L, \epsilon, D_{Y}, D_{Z}\right) \leq C$.

In Section 1.21 we will relate this definition to the more standard notion of cobounded subsets in a Gromov-hyperbolic space.

Lemma 1.26. If $Y, Z$ are $C$-Lipschitz cobounded, then for every $R$ there exists $D=$ $D_{1.26}(R, C)$ such that if

$$
a_{i} \in Y, b_{i} \in Z, i=1,2
$$

are points satisfying $d\left(a_{i}, b_{i}\right) \leq R, i=1,2$, then $d\left(a_{1}, a_{2}\right) \leq D, d\left(b_{1}, b_{2}\right) \leq D$.
Proof. One can take $D=2 C(R+1)+C$.

### 1.6. Coproducts, cones and cylinders

In this section we discuss several purely topological notions used elsewhere in the book. Let $\left\{Z_{\alpha}: \alpha \in A\right\}$ be an indexed collection of topological spaces. Then the coproduct topology on the disjoint union

$$
Z:=\coprod_{\alpha \in A} Z_{\alpha}
$$

is the finest topology on the disjoint union such that all the natural inclusion maps $Z_{\alpha} \rightarrow Z$ are continuous. In particular, each $Z_{\alpha} \subset Z$ is a clopen subset homeomorphic to $Z_{\alpha}$.

In the following two constructions, the unit intervals $[0,1]$ are sometimes replaced by the half-intervals $[0,1 / 2]$ with $1 / 2$ playing the role of 1 .

Let $X, Y$ be topological spaces, $f: X \rightarrow Y$ a continuous map. Then the mapping cylinder $C y l(f: X \rightarrow Y)$, also denoted $X \cup_{f} Y$ and, sometimes, $Y \cup_{f} X$, is the quotient of $X \times[0,1] \sqcup Y$ (with the coproduct topology) by the equivalence relation

$$
(x, 1) \sim f(x), x \in X
$$

Lastly, the cone $C(a, X)$ over a topological space $X$ is the quotient of the product $X \times[0,1]$ by the subspace $X \times\{1\}$. The point $a$, the projection of $X \times\{1\}$ in $C(a, X)$, is called the apex of the cone. The projections of the intervals $\{x\} \times[0,1]$ under the quotient map $q: X \times[0,1] \rightarrow C(a, X)$ will be called the radial line segments in $C(a, X)$. We will identify $X$ with the image of $X \times\{0\}$ in $C(a, X)$.

In the next section, we will metrize the cones $C(a, X)$.

### 1.7. Cones over metric spaces

Let $(X, d)$ be a path-metric space. We equip $X \times[0,1 / 2]$ with the product metric. We metrize the corresponding cone $C(a, X)$ as follows. Projecting rectifiable paths

$$
c: I=[0,1] \rightarrow X \times[0,1 / 2]
$$

we obtain a family of admissible paths in $C(a, X)$. For a rectifiable path $c$, we define the length $L(q(c))$ to be equal to the length of $c$ minus the total length of the intersection $c(I) \cap X \times\{1 / 2\}$. In other words, the length of the path $q \circ c$ is the total length of $\left.c\right|_{J}$, where $J=I \backslash(q \circ c)^{-1}(\{p\})$. For instance, the radial line segment connecting $x$ to $a$ has length $1 / 2$. Using this notion of length we path-metrize the cone $C(a, X)$. We leave it to the reader to check that this metric, denoted $\hat{d}$, metrizes the topology of $C(a, X)$ and that for each $x \in X$,

$$
\hat{d}(x, a)=1 / 2
$$

### 1.8. Approximation of metric spaces by metric graphs

In this section we discuss a generalization of path-metric spaces, called quasi-path metric spaces.

Definition 1.27. A finite $r$-path in a metric space $(X, d)$ is a map

$$
c:[m, n] \subset \mathbb{Z} \rightarrow X
$$

such that $d(c(i), c(i+1)) \leq r$ for all $m \leq i \leq n-1$. The length of such $c$ is defined as

$$
\text { length }(c)=\sum_{i=m}^{n-1} d(c(i), c(i+1))
$$

The finite path $c$ is said to connect the point $x=c(m)$ to the point $y=c(n)$.

A metric space $(X, d)$ is called an $r$-quasi-path metric space for a constant $r>0$ if for every pair of points $x, y \in X$ there exists a finite $r$-path $c$ connecting $x$ to $y$ such that length $(c) \leq d(x, y)+r$.

For instance, every path-metric space is an $r$-quasi-path metric space for every $r>0$.
Lemma 1.28. Any r-quasi-path metric space is (1,3r)-quasiisometric to a path-metric space.

Proof. Suppose $X$ is an $r$-quasi-path metric space. We construct a metric graph $Z$ with the vertex set $V(Z)=X$ such that $x, y \in X$ are connected by an edge $e$ iff $x \neq y$ and $d_{X}(x, y) \leq r$, where the edge is assigned the length $\ell(e)=d_{X}(x, y)$.

Consider the inclusion map $\iota: X \rightarrow Z$. Suppose $x, y \in X$ are arbitrary points. Then there is an $r$-path $x=x_{0}, x_{1}, \cdots, x_{n}=y$ in $X$ joining $x$ to $y$ in $X$. By the definition of the graph $Z, x_{i}$ 's also form a sequence of vertices connected by edges in $Z$. Hence,

$$
d_{Z}(x, y) \leq \sum_{i} d_{Z}\left(x_{i}, x_{i+1}\right) \leq \sum_{i} d_{X}\left(x_{i}, x_{i+1}\right) \leq d_{X}(x, y)+r .
$$

Thus, $\iota$ is $(1, r)$-coarse Lipschitz. Let $\rho: Z \rightarrow X$ be the following map. The restriction of $\rho$ on $V(Z)$ is simply the identity map and interiors of edges are mapped to one of the vertices. Let $\alpha: I \rightarrow Z$ be any piecewise-linear path (see [BH99], Chapter I.1, Section 1.9). Then clearly, length $(\alpha)$ and the length of the $r$-path $\rho \circ \alpha$ differ by at most $2 r$. Hence, $\rho$ is $(1,2 r)$-coarsely Lipschitz. Moreover, it is clear that $d\left(\mathrm{id}_{X}, \rho \circ \iota\right) \leq r$ and $d\left(\mathrm{id}_{Z}, \iota \circ \rho\right) \leq r$. Hence, by Lemma 1.14, the maps $\iota, \rho$ are both ( $1,3 r$ )-quasiisometries.

Definition 1.29 (Rips graph). Let $(Y, d)$ be a metric space. For $R \geq 0$ the $R$-Rips graph of $(Y, d)$ is the graph $Z_{R}$ with the vertex-set $Y$ and edges $\left[y_{1}, y_{2}\right.$ ] for all pairs of distinct points $y_{1}, y_{2} \in Y$ such that $d\left(y_{1}, y_{2}\right) \leq R$. We will equip $Z$ with its graph-metric (each edge has unit length).

Note that for a general metric space $Y$, the graph $Z_{R}$ is disconnected and the distance between points in different connected components is infinite. However, if $Y$ is a path-metric space, then each graph $Z_{R}$ is connected.

Definition 1.30. A metric space $(Y, d)$ is said to be coarsely connected if there exists $R<\infty$ such that the corresponding Rips graph $Z_{R}$ is connected.

The following fundamental result of geometric group theory is usually stated for proper metric spaces $Y$ and properly discontinuous actions, but, when the notion of metrically proper actions is used, properness of $Y$ is not needed and the proof is the same as in the proper case, cf. [DK18]:

Lemma 1.31 (Milnor-Schwarz Lemma). Suppose that $(Y, d)$ is a (nonempty) metric space, $G$ is a discrete group and $G \curvearrowright Y$ is a geometric action. Then:

1. If $Y$ is coarsely connected, then $G$ is finitely generated.
2. If $Y$ is a quasi-path metric space, then for one (equivalently, every) $y \in Y$ the orbit map $G \rightarrow G y \subset Y$ is a quasiisometry.

Lemma 1.32. For a path-metric space $X$, let $Z=Z_{1}$ be the 1-Rips graph of $X$. Then the inclusion map $\iota: X \rightarrow Z$ is a $(1,1)$-quasiisometry with a $(1,3)$-qi inverse $\rho: Z \rightarrow X$.

[^2]Proof. The proof is very similar to that of the previous lemma: We let the map $\rho$ : $Z \rightarrow X$ be identity on the $V(Z)=X$, etc. Given $x, y \in X$, we join them in $X$ by an arclength parametrized path $\gamma:[0, l] \rightarrow X$ such that $l \leq d_{X}(x, y)+\epsilon$, where $\epsilon>0$ is chosen in such a way that $d_{X}(x, y)<m+1$ where $m$ is the nonnegative integer determined by $m \leq d(x, y)<m+1$. Since length $(\gamma)<m+1$, it follows that $d_{Z}(x, y) \leq m+1 \leq d_{X}(x, y)+1$. Suppose $x, y \in X$ such that $d_{Z}(x, y)=n$. Let $x=x_{0}, x_{1}, \cdots, x_{n}=y$ the consecutive vertices on a geodesic in $Z$ joining $x, y$. Then we know that $d_{X}\left(x_{i}, x_{i+1}\right) \leq 1$. Thus,

$$
d_{X}(x, y) \leq \sum_{i=1}^{n} d_{X}\left(x_{i-1}, x_{i}\right) \leq n
$$

and we get $d_{X}(x, y) \leq d_{Y}(f(x), f(y)) \leq d_{X}(x, y)+1$. This proves the first statement of the lemma.

Finally, $\iota(X)$ is a 1-net in $Z$, and, hence, $\iota$ is coarsely 1 -surjective. The remaining parts of the proof follow from simple calculations and we leave details to the reader.

Corollary 1.33. Suppose $X$ is an r-quasi-path metric space. Then there is a (connected) graph $X^{\prime}$ equipped with the graph-metric and $a(1,3 r+1)$-quasiisometry $\iota: X \rightarrow X^{\prime}$ with a $(1,3 r+3)$-qi inverse $\rho: X^{\prime} \rightarrow X$ such that $\rho\left(X^{\prime}\right)=X$. In particular, each quasi-path metric space is $(1, \epsilon)$-quasiisometric to a geodesic metric space.

Proof. This is a straightforward consequence of Lemma 1.28 and Lemma 1.32.
Lemma 1.34 (Local-to-global principle for coarse Lipschitz maps from quasipath metric spaces). Suppose that $\left(X, d_{X}\right)$ is an r-quasi-path metric space, $\left(Y, d_{Y}\right)$ is any metric space and $f: X \rightarrow Y$ is a map such that for all $x_{1}, x_{2} \in X, d_{X}\left(x_{1}, x_{2}\right) \leq r$ implies that $d_{Y}\left(f\left(x_{1}\right), f\left(x_{2}\right)\right) \leq r^{\prime}$ for some $r^{\prime}$ independent of $x_{1}, x_{2}$. Then $f$ is $\left(\frac{2 r^{\prime}}{r}, 3 r^{\prime}\right)$-coarse Lipschitz.

Proof. Take $x, y \in X$. Suppose $n \in \mathbb{N}$ is the smallest integer such that there is a finite sequence $x_{0}=x, x_{1}, \cdots, x_{n}=y$ in $X$ with $d_{X}\left(x_{i}, x_{i+1}\right) \leq r$ for all $i=0, \ldots, n-1$ and $\sum_{i=0}^{n-1} d_{X}\left(x_{i}, x_{i+1}\right) \leq d(x, y)+r$. Then $d_{X}\left(x_{i}, x_{i+2}\right)>r$ for $0 \leq i \leq n-2$. It follows that $r(n-1) / 2<d_{X}(x, y)+r$. Hence, $n<3+\frac{2}{r} d_{X}(x, y)$. On the other hand

$$
d_{Y}(f(x), f(y)) \leq \sum_{i=0}^{n-1} d_{Y}\left(f\left(x_{i}\right), f\left(x_{i+1}\right)\right) \leq n r^{\prime}<3 r^{\prime}+\frac{2 r^{\prime}}{r} d_{X}(x, y)
$$

Let $Y$ be a $D$-net in metric space $(X, d)$ with the inclusion map $\iota: Y \rightarrow X$. Given $R>0$ we let $Z=Z_{R}$ be the full subgraph of the $R$-Rips graph of ( $X, d_{X}$ ) with the vertex set $Y$; we equip $Z$ with its graph-metric. We extend the map $\iota$ to the rest of $Z$, (the extension is still denoted by $\iota$ ), by taking an arbitrary orientation on $Z$ and sending all points of any open directed edge $[v, w] \backslash\{w\}=[v, w)$ in $Z$ to the point $v \in Y \subset X$. The next lemma (which is a form of the Milnor-Schwarz Lemma for metric spaces, cf. Theorem 8.52 in [DK18]) shows that, under some conditions, the graph $Z$ is connected and the map $\iota$ is a uniform quasiisometry $Z \rightarrow X$. This result generalizes Lemma 1.32.

Lemma 1.35. Suppose $\left(X, d_{X}\right)$ is an $r$-quasi-path metric space and $Y \subset X$ is a $D$-net in $X$. If $R \geq r+2 D$, then $Z$, as defined above, is a connected graph and the map $\iota:\left(Z, d_{Z}\right) \rightarrow X$ is a $\left(K_{1.35}(r, R), \epsilon_{1.35}(r, R)\right)$-quasiisometry.

Moreover, there is a $(1+r)$-coarse inverse $\rho: X \rightarrow Z$ to $\iota$ such that $\rho(x)=x$ for all $x \in Y$ which is also $a\left(K_{1.35}(r, R), \epsilon_{1.35}(r, R)\right)$-quasiisometry.

Proof. 1. Consider vertices $y, y^{\prime} \in Y$. Since $(X, d)$ is a $r$-quasi-path metric space, there exists an $r$-path

$$
y=x_{0}, x_{1}, \ldots, x_{n} x_{n+1}=y^{\prime}
$$

in $X$ from $y$ to $y^{\prime}$. Since $Y \subset X$ is a $D$-net in $X$, there exist points $y_{1}, \ldots, y_{n} \in Y$ satisfying

$$
d_{X}\left(x_{i}, y_{i}\right) \leq D, i=1, \ldots, n
$$

By the triangle inequality, $d_{X}\left(y_{i}, y_{i+1}\right) \leq r+2 D \leq R$ for $i=0, \ldots, n$ where $y_{n+1}=y^{\prime}$, which implies that the vertices $x_{0}=y, y_{1}, \ldots, y_{n}, y^{\prime}$ are on an edge path in $Z$. This proves that $Z$ is connected.

Suppose $z \neq z^{\prime} \in Z$ are any two points. Let $\iota(z)=y, \iota\left(z^{\prime}\right)=y^{\prime}$ and let $z, y_{0}, \cdots, y_{n}, z^{\prime}$ be a geodesic in $Z$ joining $z, z^{\prime}$ where $y_{i} \in Y$. We note that $d_{Z}\left(y, y_{0}\right) \leq 1, d_{Z}\left(y_{n}, y^{\prime}\right) \leq 1$ and $\left|d_{Z}\left(z, z^{\prime}\right)-n\right| \leq 2$. Now,

$$
\begin{array}{r}
d_{X}\left(\iota(z), \iota\left(z^{\prime}\right)\right) \leq d_{X}\left(y, y_{0}\right)+d_{X}\left(y_{n}, y^{\prime}\right)+\sum_{i=0}^{n} d_{X}\left(y_{i}, y_{i+1}\right) \leq \\
2 R+n R \leq 2 R+R\left(d_{Z}\left(z, z^{\prime}\right)+2\right)=4 R+R d_{Z}\left(z, z^{\prime}\right) .
\end{array}
$$

Hence the map $\iota: Z \rightarrow X$ is $(R, 4 R)$-coarse Lipschitz.
Next, we define a coarse inverse map $\rho$ to $\iota$ by defining it to be the identity map on $Y$ and sending $x \in X \backslash Y$ to a point $\rho(x)=y \in Y$ such that $d_{X}(x, y) \leq D$. Then $d_{X}\left(x, x^{\prime}\right) \leq r$ implies that $d_{X}\left(\rho(x), \rho\left(x^{\prime}\right)\right) \leq r+2 D \leq R$, i.e. $d_{Z}\left(\rho(x), \rho\left(x^{\prime}\right)\right) \leq 1$. Since $(X, d)$ is a $r$-quasi-path metric space, the map $\rho$ is $(2 / r, 3)$-coarse Lipschitz by Lemma 1.34.

By the construction,

$$
d(\rho \circ \iota(t), t) \leq 1, \quad d(\iota \circ \rho(x), x) \leq r .
$$

Hence, by Lemma 1.14 we can take

$$
K_{1.35}(r, R)=\max \{R, 2 / r\}, \quad \epsilon_{1.35}(r, R)=\max \{4 R, 3\}+2 \max \{1, r\} .
$$

Similarly to the approximation of coarse Lipschitz maps of line segments by piecewiselinear maps, one has a uniform approximation of coarse Lipschitz maps of metric (simplicial) graphs by simplicial maps, i.e. maps sending every edge linearly to an edge or a vertex.

Lemma 1.36. Fix numbers $R, L, \epsilon$. Let $X, Y$ be connected metric graphs with the same edge-length $R$. Then, after subdividing edges of $X$ in at most $n(R, L, \epsilon)$ equal length subsegments, every $(L, \epsilon)$-coarse Lipschitz map $f: X \rightarrow Y$ is within distance $D_{1.36}(L, \epsilon, R)$ from a simplicial map $f_{*}: X \rightarrow Y$.

Proof. The proof is similar to that of Lemma 1.22 and we omit it.
Since $Z$ constructed in this lemma is a complete geodesic metric space and since we are interested in coarse geometric properties of metric spaces, we can always replace quasipath metric spaces with appropriate metric graphs. We will be using this in Section 2.2 when constructing total spaces of trees of spaces.

### 1.9. Hyperbolic metric spaces

Hyperbolic metric spaces are coarsifications of the classical hyperbolic $n$-space $\mathbb{H}^{n}$ and are characterized by a form of thin triangle condition. The most common notions of hyperbolicity for metric spaces are the one due to Rips (for geodesic metric spaces) and one due to Gromov (for general metric spaces). One drawback of Gromov's definition is that his notion of hyperbolicity is not qi invariant, although it is invariant under $(1, \epsilon)$ quasiisometries. One of the features (or bugs, depending on the perspective) of metric hyperbolicity is that it is stable under changes in metric below certain scale $\delta$ and that, accordingly, nothing can be said about general hyperbolic spaces below that scale. This
also points to a limitation of Rips' notion of hyperbolicity since it applies only to geodesic metric spaces. This becomes somewhat important in the context of this book since metric spaces that we consider are frequently only path-metric spaces. One source where hyperbolicity along the lines of Rips definition is developed for path-metric spaces $X$ is Väisälä's paper [V0̈5]: Instead of geodesics he considers $h$-short paths, which are rectifiable paths between points $x, y \in X$ whose length is at most $d(x, y)+h$. A drawback is that one is forced to carry an extra constant. Another possible approach is to extend Rips' definition to the class of quasi-path metric spaces. We will give basic definitions in Section 1.9.3 but will not pursue this direction much further beyond proving that such metric spaces are $(1, \epsilon)$-quasiisometric to geodesic metric spaces and, hence, Gromov's notion of hyperbolicity in the context of quasi-path metric spaces is preserved by general quasiisometries, see Section 1.9.4. Yet, another possible approach is to work with path-metric spaces but instead of geodesics, work with sequences of paths whose lengths approximate distances between points. All the arguments appearing in the book will go through with constants unchanged comparing to the ones for geodesic metric spaces. A drawback is that this approach lengthens the proofs (which are already long and technical in chapters 3, 4, 5 and 6 ). Thus, for most of the book, we work with geodesic metric spaces. In this section we present various notions of hyperbolicity starting with the most familiar ones.

We assume that the reader is familiar with the basic definitions and facts about hyperbolic metric spaces that can be found for instance in [BH99], [CDP90], [DK18], [Gro87], [Gd90], [ABC ${ }^{+} 91$ ], [V0̈5]. In this section we collect some of these to fix the notions and for later use.

### 1.9.1. Hyperbolicity in the sense of Gromov.

Definition 1.37 (Gromov product). Let $X$ be a metric space. Given points $x, y, z \in X$, the Gromov product of $y, z$ with respect to $x$, denoted $(y . z)_{x}$, is defined as

$$
\frac{1}{2}(d(x, y)+d(x, z)-d(y, z)) .
$$

Defintition 1.38. A metric space $X$ is said to be $\delta$-hyperbolic in the sense of Gromov or simply $\delta$-Gromov-hyperbolic if all $x, y, z, w \in X$ satisfy the inequality

$$
(x . y)_{w} \geq \min \left\{(x . z)_{w},(y . z)_{w}\right\}-\delta .
$$

A metric space $X$ is said to be hyperbolic in the sense of Gromov if it is $\delta$-Gromovhyperbolic for some $\delta \in[0, \infty)$.

A finitely-generated group $G$ is called hyperbolic if the metric space ( $G, d_{G}$ ) is hyperbolic in the sense of Gromov, where $d_{G}$ is the word metric on $G$ for some finite generating set.

Example 1.39. Consider the graph $G \subset \mathbb{R}^{2}$ of the function $y=|x|$. We equip $G$ with the restriction of the standard Euclidean metric on $\mathbb{R}^{2}$. For $n \in \mathbb{N}$ consider points

$$
o=(0,0), p=(-n, n), q=(n, n), z=(2 n, 2 n) .
$$

Then $(p, q)_{o}=(\sqrt{2}-1) n,(p, z)_{o}=2 \sqrt{2} n,(q, z)_{o}=\sqrt{2} n$. The difference

$$
(p \cdot q)_{o}-\min \left\{(p \cdot z)_{o},(q \cdot z)_{o}\right\}=(\sqrt{2}-1) n-\sqrt{2} n=-n
$$

diverges to $-\infty$ as $n \rightarrow \infty$. Thus, $G$ is not hyperbolic in the sense of Gromov. On the other hand, $G$ is qi to the real line via the map $x \mapsto(x,|x|)$ and the real line is 0 -hyperbolic.

Thus, Gromov-hyperbolicity is not preserved by quasiisometries even for quasigeodesic metric spaces, i.e. metric spaces where all points are connected by uniform quasigeodesics. On the other hand, the following lemma is straightforward from the definition of Gromov-hyperbolicity:

Lemma 1.40. Suppose $X, Y$ are metric spaces and $f: X \rightarrow Y$ is a $(1, \epsilon)$-quasiisometry for some $\epsilon \geq 0$. Then $X$ is Gromov-hyperbolic iff $Y$ is. More precisely, if $X \delta$-hyperbolic in the sense of Gromov, then $Y$ is $\delta+3 \epsilon$-hyperbolic in Gromov's sense.
1.9.2. Hyperbolicity in the sense of Rips. Suppose now that $X$ is a geodesic metric space.

Definition 1.41. Consider a geodesic triangle $\Delta=\Delta x_{1} x_{2} x_{3} \subset X$ with the vertices $x_{1}$, $x_{2}, x_{3}$, and let $\delta \geq 0$.
(1) The triangle $\Delta$ is said to be $\delta$-slim if each side of $\Delta$ is contained in the $\delta$ neighborhood of the union of the other two sides.
(2) For all $i \neq j \neq k \neq i$, let $c_{k} \in x_{i} x_{j}$ be such that $d\left(x_{i}, c_{j}\right)=d\left(x_{i}, c_{k}\right)$. The points $c_{i}$ are called the internal points of $\Delta$. Note that, for all $i \neq j \neq k \neq i$,

$$
d\left(x_{i}, c_{j}\right)=\frac{1}{2}\left(d\left(x_{i}, x_{j}\right)+d\left(x_{i}, x_{k}\right)-d\left(x_{j}, x_{k}\right)\right)=\left(x_{j} \cdot x_{k}\right)_{x_{i}} .
$$

(3) If $X$ is a tree, then $p=c_{1}=c_{2}=c_{3}$ and in this case we shall refer to the point $p$ as the center of the $\Delta$.
(4) The diameter of the set $\left\{c_{1}, c_{2}, c_{3}\right\}$ will be referred to as the insize of the triangle $\Delta$.
(5) The triangle $\Delta$ is said to be $\delta$-thin if for all $i \neq j \neq k \neq i$ and $p \in x_{i} c_{j} \subset x_{i} x_{k}$, $q \in x_{i} c_{k} \subset x_{i} x_{j}$ with $d\left(p, x_{i}\right)=d\left(q, x_{i}\right)$, one has

$$
d(p, q) \leq \delta
$$

The next lemma is clear from the definitions:
Lemma 1.42. If $\Delta$ is $\delta$-thin, then it is also $\delta$-slim and its insize is $\leq \delta$.
Definition 1.43 (Rips hyperbolicity). A geodesic metric space $X$ is said to be $\delta$ hyperbolic in the sense of Rips if each geodesic triangle in $X$ is $\delta$-slim. A geodesic metric space is said to be Rips-hyperbolic if it is $\delta$-hyperbolic in the sense of Rips for some $\delta<\infty$.

Lemma 1.44 (Proposition 2.1 in [ $\left.\mathbf{A B C}^{+} \mathbf{9 1}\right]$ ). Suppose $X$ is a $\delta$-hyperbolic metric space in the sense of Rips. Then the following hold:
(1) All the geodesic triangles in $X$ have insize at most $4 \delta$.
(2) All the geodesic triangles in $X$ are $6 \delta$-thin.

It follows that a geodesic metric space is hyperbolic in the sense of Rips if and only if all geodesic triangles in $X$ are uniformly thin.

The following lemmata are also very standard and follow easily from definitions, see for instance [DK18], [ABC ${ }^{+} 91$ ], or [V0̈5]:

Lemma 1.45. A geodesic metric space is Rips-hyperbolic if and only it is Gromovhyperbolic. More precisely:
(1) If a metric space $X$ is $\delta$-hyperbolic in the sense of Rips, then $X$ is $3 \delta$-hyperbolic in Gromov's sense.
(2) If $X$ is geodesic and $\delta$-hyperbolic in Gromov's sense, then $X$ is $2 \delta$-hyperbolic in the sense of Rips.

In view of this lemma, when talking about hyperbolicity for geodesic metric spaces, we will always mean hyperbolicity in the sense of Rips.

For geodesic hyperbolic spaces, the Gromov-product $(y . z)_{x}$ "almost equals" the distance from $x$ to the geodesic $y z$ :

Lemma 1.46. Suppose that $X$ is a $\delta$-hyperbolic space in the sense of Rips. Then for each triple $x, y, z \in X$,

$$
(y . z)_{x}-2 \delta \leq(y . z)_{x} \leq d(x, y z)
$$

Lemma 1.47. Every geodesic quadrilateral $\square=x y z w$ in a $\delta$-hyperbolic metric space $X$ is $2 \delta$-slim, i.e. the side xy of $\square$ is contained in the $2 \delta$-neighborhood of the union of the other three sides of $\square$. Similarly, each geodesic $n$-gon in $X$ is $(n-2) \delta$-slim.
1.9.3. Hyperbolicity for path-metric spaces. The form of Rips-hyperbolicity discussed in this section is a mild generalization of Rips-hyperbolicity for geodesic metric spaces. We refer the reader to [V0̈5] for a more general discussion.

Definition 1.48. A rectifiable path $c$ connecting $x$ to $y$ in a metric space $X$ is called $\epsilon$-short if

$$
\operatorname{length}(c) \leq d(x, y)+\epsilon
$$

Definition 1.49 (Triangles formed by paths). Suppose $X$ is any metric space. Given any three points $x, y, z \in X$ and three (continuous or finite) paths $c(x, y), c(x, z), c(y, z)$ joining these points, the triangle formed by these paths is the set $\{c(x, y), c(x, z), c(y, z)\}$ and the members of this set will be called the sides of the triangle.

Definition 1.50 (Slimness constant for a path-family). (1) Suppose $X$ is a metric space and $x, y, z \in X$. We shall say that a triangle formed by three paths $c(x, y), c(x, z), c(y, z)$ is $\delta$ slim for some $\delta \geq 0$, if each side of the triangle is contained in the union of $\delta$-neighborhoods of the remaining two sides.
(2) Given a family $C$ of paths $c(x, y)$ connecting points $x, y$ in a metric space $X$, for all $x \neq y \in X$ we define the slimness constant of $C$ as

$$
\delta_{s}(C):=\sup _{c(x, y), c(y, z), c(z, x) \in C} \inf \{r: \text { the triangle }\{c(x, y), c(y, z), c(z, x)\} \text { is } r \text {-slim }\} .
$$

We are now ready to define a form of Rips-hyperbolicity for path-metric spaces:
Definition 1.51 (Rips hyperbolicity of path-metric spaces). If $(X, d)$ is a path-metric space, and $\epsilon \geq 0$, let $\mathcal{F}_{\epsilon}$ be the family of all $\epsilon$-short paths $c(x, y)$ in $X$. We say that $X$ is $\delta$-hyperbolic in the sense of Rips if

$$
\limsup _{\epsilon \rightarrow 0+} \delta_{s}\left(\mathcal{F}_{\epsilon}\right) \leq \delta .
$$

Remark 1.52. (1) $(X, d)$ is a geodesic metric space if and only if the set $\mathcal{F}_{0}$ is nonempty. Elements of $\mathcal{F}_{\epsilon}$ are $(1, \epsilon)$-quasigeodesics in $X$.
(2) For a geodesic metric space, Definition 1.51 is equivalent to the standard notion of $\delta$-hyperbolicity in the sense of Rips (with a slightly different hyperbolicity constant). There, a space is $\delta_{0}$-hyperbolic (in the sense of Rips) if $\delta\left(\mathcal{F}_{0}\right)=\delta_{0}$.
(3) If for a path-metric space $X$ we have $\delta\left(\mathcal{F}_{\epsilon}\right)<\infty$ for some $\epsilon \geq 0$, then $X$ is $\delta\left(\mathcal{F}_{\epsilon}\right)$-hyperbolic in the sense of Rips.
1.9.4. Stability of quasigeodesics and qi invariance of hyperbolicity. One of the most fundamental facts about hyperbolic spaces is that quasigeodesics are uniformly close to geodesics. This fact is also known as the (hyperbolic) Morse lemma, as it first appeared in a work of Morse on geodesics in the hyperbolic plane, [Mor24]. Morse did not have the notion of quasigeodesics and he was interested in how geodesics on a surface change with a change of its hyperbolic metric. Since changing a Riemannian metric on a compact manifold results in a quasiiisometric change of the metric on its universal cover, Morse's result can be interpreted as stability of quasigeodesics. Morse's proof was quite general and most modern proofs of stability of quasigeodesics follow the same line of reasoning.

The next lemma is a converse to Lemma 1.20 in the setting of hyperbolic spaces.
Lemma 1.53 (Morse Lemma or stability of quasigeodesics). There is a function $D_{1.53}=D_{1.53}(\delta, k)$ defined for $\delta \geq 0$ and $k \geq 1$, such that the following holds:

Suppose $X$ is a $\delta$-hyperbolic geodesic metric space. Then for every $k$-quasigeodesic $\phi:[a, b] \rightarrow X$, the Hausdorff distance between the image of $\phi$ and that of the geodesic $\phi^{*}$ connecting the end-points of $\phi$, is $\leq D_{1.53}$.

More precisely, according to [GS19], for a $(k, \epsilon)$-quasigeodesic $\phi$ in $X$,

$$
\operatorname{Hd}\left(\phi, \phi^{*}\right) \leq 92 k^{2}(\epsilon+3 \delta) .
$$

Thus, for a $k$-quasigeodesic one can take

$$
D_{1.53}(\delta, k)=92 k^{2}(k+3 \delta) .
$$

With minor modifications, the proofs go through for path-metric spaces, when geodesics are replaced with $\eta$-short paths $\phi_{\eta}^{*}$ (cf. [V0̈5]). One obtains an estimate $D_{1.53}(\delta, k, \eta)$ and, hence,

$$
D_{1.53}(\delta, k)=\lim _{\eta \rightarrow 0+} D_{1.53}(\delta, k, \eta) .
$$

As a consequence:
Lemma 1.54. There exists a function $D=D_{1.54}(\delta, k, r) \geq r$ such that the following holds. If $X$ be a $\delta$-hyperbolic geodesic space, and $\phi_{i}: I_{i}=\left[a_{i}, b_{i}\right] \rightarrow X$ are $k$ quasigeodesics satisfying

$$
d\left(x_{1}, x_{2}\right) \leq r, d\left(y_{1}, y_{2}\right) \leq r, x_{i}=\phi_{i}\left(a_{i}\right), y_{i}=\phi_{i}\left(b_{i}\right), i=1,2,
$$

then the images $\phi_{1}\left(I_{1}\right), \phi_{2}\left(I_{2}\right)$ are $D$-Hausdorff close.
Proof. Let $\phi_{i}^{*}$ be geodesics connecting the end-points $x_{i}, y_{i}$ of $\phi_{i}, i=1,2$. Then, since quadrilaterals in $X$ as $2 \delta$-slim,

$$
\operatorname{Hd}\left(\phi_{1}^{*}, \phi_{2}^{*}\right) \leq 2 \delta+r .
$$

Applying Lemma 1.53, we conclude that

$$
\operatorname{Hd}\left(\phi_{1}, \phi_{2}\right) \leq D_{1.54}(\delta, k, r)=\max \left(2 D_{1.53}(\delta, k)+\delta, D_{1.53}(\delta, k)+\delta+r\right) .
$$

More explicitly, since $D_{1.53}(\delta, k)=92 k^{2}(k+3 \delta)$, we get:

$$
D_{1.54}(\delta, k, r)=\max \left(184 k^{2}(k+3 \delta)+\delta, 92 k^{2}(k+3 \delta)+\delta+r\right)
$$

Lemma 1.55. Suppose that $Y, X$ are path-metric spaces, $X$ is $\delta$-Rips-hyperbolic and $f: Y \rightarrow X$ is a $(K, \epsilon)$-qi embedding. Then $Y$ is also $\delta_{1.55}(\delta, K, \epsilon)$-hyperbolic.

In particular, (Rips) hyperbolicity is qi invariant among path-metric spaces:
If $f: Y \rightarrow X$ is a $(K, \epsilon)$-quasiisometry and $X$ is $\delta$-hyperbolic in the sense of Rips, then $Y$ is $\delta_{1.55}^{\prime}(\delta, K, \epsilon)$-hyperbolic in the sense of Rips.

Proof. Consider a triple of points $x, y, z \in Y$ and for $\eta \geq 0$ take the triangle $\Delta_{\eta}$ in $Y$ formed by $\eta$-short arc-length parameterized paths $c(x, y), c(y, z), c(z, x)$ connecting these points. These paths are $(1, \eta)$-quasigeodesics in $Y$.

Then $f(c(x, y)), f(c(x, z)), f(c(y, z))$ are $\left(K, \epsilon^{\prime}\right)$-quasigeodesics in $X$, for

$$
\epsilon^{\prime}=K(1+\eta)+\epsilon,
$$

see Lemma 1.11. Hence, by Lemma 1.53, the quasigeodesic triangle formed by the quasigeodesic paths $f(x y), f(x z), f(y z)$ is $D=\left(2 \cdot 92 K^{2}\left(\epsilon^{\prime}+3 \delta\right)+\delta\right)$-slim. This implies that the triangle $\Delta_{\eta}$ is $K(D+\epsilon)$-slim. Sending $\eta$ to 0 , we conclude that $Y$ is $\delta_{1.55}(\delta, K, \epsilon)$-hyperbolic for

$$
\delta_{1.55}(\delta, K, \epsilon)=K\left(184 K^{2}(K+\epsilon+3 \delta)+\delta+\epsilon\right)
$$

The second statement of the lemma follows from the first, combined with Lemma 1.12.
Remark 1.56. For $\epsilon=K$ we will use then notation $\delta_{1.55}(\delta, K, \epsilon)=\delta_{1.55}(\delta, K)$ and $\delta_{1.55}^{\prime}(\delta, K, \epsilon)=\delta_{1.55}^{\prime}(\delta, K)$. Thus, for $\delta_{1.55}(\delta, K)$ we can take the number

$$
K\left(184 K^{2}(2 K+3 \delta)+\delta+K\right)
$$

Lemma 1.55 combined with Lemma 1.45 immediately imply:
Corollary 1.57. Hyperbolicity is qi invariant among path-metric spaces.
Corollary 1.58. Gromov-hyperbolicity is qi invariant among quasi-path metric spaces.
Proof. Suppose that $X, Y$ are quasiisometric quasi-path metric spaces and $X$ is Gromovhyperbolic. By Corollary 1.33 , there are metric graphs $X^{\prime}, Y^{\prime}$ which are geodesic metric spaces, and are $(1, \epsilon)$-quasiisometric to $X$ and $Y$ respectively for a suitable $\epsilon \geq 0$. Thus:
(1) by Lemma $1.40 X^{\prime}$ is Gromov hyperbolic.
(2) $X^{\prime}, Y^{\prime}$ are quasiisometric geodesic metric spaces.

However, then by Corollary $1.57, X^{\prime}$ is Rips-hyperbolic since it is a geodesic metric space. Then, by Lemma $1.55, Y^{\prime}$ is also Rips hyperbolic. Since $Y^{\prime}$ is a geodesic metric space, again by Lemma 1.45, it is also Gromov-hyperbolic. Finally, $Y$ is also Gromovhyperbolic by Lemma 1.40.

As another corollary we get:
Corollary 1.59. Suppose that $Y$ is a path-metric space, $X \subset Y$ is a rectifiably connected $R$-net in $Y\left(N_{R}(X)=Y\right)$, equipped with a path-metric such that the inclusion map $X \rightarrow Y$ is $\eta$-uniformly proper, and $X$ is $\delta$-hyperbolic. Then $Y$ is $\delta_{1.59}(\delta, \eta(2 R+1), R)=$ $\delta_{1.55}(\delta, \eta(2 R+1))$-hyperbolic.

Proof. According to Lemma 1.17, the inclusion map $X \rightarrow Y$ is an $L$-qi embedding, $L=\eta(2 R+1)$, hence, an $L$-quasiisometry. Now the corollary follows immediately from Lemma 1.55.

### 1.10. Combings and a characterization of hyperbolic spaces

One of the key tools in our work is a characterization of hyperbolicity in terms of slim combings due to Bowditch. The idea is that if $X$ is a $\delta$-hyperbolic geodesic metric space, then for each pair of points we have a (typically non-unique) geodesic path $x y$ between these points and these paths satisfy the $\delta$-slim triangle property. Bowditch's characterization reverses this definition.

Let $\mathcal{P}(X)$ denote the space of paths in a topological space $X$.

Definition 1.60. 1. Two paths in a metric space are said to Hausdorff D-fellow-travel if their images are $D$-Hausdorff-close.
2. A combing $C$ of a metric space $X$ is a map

$$
c: X_{0} \times X_{0} \rightarrow \mathcal{P}(X)
$$

sending each pair $(x, y) \in X_{0}^{2}$ to a path $c_{x, y}$ in $X$ (also frequently denoted $\left.c(x, y)\right)$ connecting $x$ to $y$, where $X_{0} \subset X$ is a $D$-net for some $D$.
3. For a function $C=C(r)$, a combing $C$ is said to satisfy the $C(r)$-Hausdorff fellowtraveling property if for every triple of points $x, y, z \in X_{0}$ with $d(y, z) \leq r$,

$$
\operatorname{Hd}\left(c_{x, y}, c_{x, z}\right) \leq C(r)
$$

and $\operatorname{diam}\left(c_{x, x}\right) \leq C(0)$.
While we define combings as maps, we will think of each combing as a subset $C=$ $c\left(X^{2}\right) \subset \mathcal{P}(X)$.

Lemma 1.61. Suppose that we have a combing $C$ in a metric space $X$ such that:

1. Every path $c \in C$ is a concatenation of at most $n$ subpaths each of which is in $C$ and is $\eta$-proper.
2. The family $C$ satisfies the $C$-Hausdorff fellow-traveling property.
3. The family $C$ is consistent in the sense that for each triple of points $x, y, z \in X$ such that $y \in c=c_{x, z}$, the subpath $c(x, y)$ of $c$ between $x$ and $y$ is $R$-Hausdorff close to the path $c_{x, y}$.

Then the family $C$ is uniformly proper. More precisely, there is a function

$$
\zeta_{1.61}(r, C, R, \eta, n)
$$

such that for each path $c: I \rightarrow X$ in $C$, for all $s, t \in I$,

$$
d(c(s), c(t)) \leq r \Rightarrow d(s, t) \leq \zeta(r, C, R, \eta, n)
$$

Proof. Consider a path $c=c_{1} \star \ldots \star c_{n}$ in $C, p=c(s), q=c_{m}(t), s<t$ and $d(p, q) \leq r$. We assume that the domain $\left[0, T_{n+1}\right]$ of $c$ is the union of subintervals $\left[T_{i}, T_{i+1}\right], i=1 \ldots, n$. By the consistency condition 3, the path $c_{p, q}$ is within the Hausdorff-distance $D$ from the subpath $\left.\right|_{[s, t]}$. By the definition of a combing, the path $c_{p, p}$ has diameter $\leq C(0)$, while by the fellow-traveling property,

$$
\operatorname{Hd}\left(c_{p, q}, c_{p, q}\right) \leq C(r)
$$

Hence, by the $\eta$-properness assumption on the subpaths $c_{i}, i=2, \ldots, n-1$, their domains have lengths $\leq \eta(C(r)+D+R)$. For the same reason,

$$
T_{1}-s \leq R, t-T_{n} \leq \eta(C(r)+C(0)+R)
$$

We, thus, obtain the required estimate $t-s \leq n \eta(C(r)+C(0)+R)=: \zeta(r, C, R, \eta, n)$.
The following characterization of hyperbolicity is due to Bowditch, [Bow14, Proposition 3.1].

Theorem 1.62. Given $h \geq 0$, there is $k=k_{1.62}(h)<\infty$ with the following property. Suppose that $X$ is a connected graph, and that for all $x, y \in V(X)$, we have associated a connected subgraph, $Y_{x y} \subset X$ containing both $x$ and $y$, satisfying the following properties.
(1) For all $x, y \in V(X)$ with $d(x, y) \leq 1$, the diameter of $Y_{x y}$ in $X$ is at most $h$.
(2) For all $x, y, z \in V(X), Y_{x y} \subset N_{h}\left(Y_{x z} \cup Y_{z y}\right)$.

Then $X$ is $k$-hyperbolic. In fact, we can take any $k \geq(3 m-10 h) / 2$, where $m$ is any positive real number satisfying $2 h\left(6+\log _{2}(m+2)\right) \leq m$. Moreover, for all $x, y \in V(X)$, the Hausdorff distance between $Y_{x y}$ and any geodesic from $x$ to $y$ is bounded above by $m-4 h$.

In the book we will be using the following corollary of Bowditch's characterization. We will refer to the family $C$ of paths $c(x, y)$ appearing in the corollary as a slim combing of $X$. Note that Property (2) below amounts to the condition that the family $C$ is $D_{2}$-slim, i.e. $\delta_{s}(C) \leq D_{2}$, see Definition 1.50.

Corollary 1.63. Given $D_{0} \geq 0, D_{1}>0, D_{2}>0$ and a coarse Lipschitz function $\eta: \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}_{\geq 0}$ there are $\delta=\delta_{1.63}\left(D_{0}, D_{1}, D_{2}\right) \geq 0$, and $R=R_{1.63}\left(D_{0}, D_{1}, D_{2}\right) \geq 0$ such that:

Suppose $X$ is a path-metric space and $X_{0} \subset X$ is a $D_{0}$-net such that for each pair of points $x, y \in X_{0}$ we are given a rectifiable path $c(x, y)$ in $X$ joining $x, y$ with the following properties.

Property (1). For all $x, y \in X_{0}$ with $d(x, y) \leq 1+2 D_{0}$, the length of $c(x, y)$ in $X$ is at most $D_{1}$.

Property (2). For all $x, y, z \in X_{0}, c(x, y) \subset N_{D_{2}}(c(x, z) \cup c(z, y))$.
Then $X$ is $\delta$-hyperbolic in the sense of Rips. Moreover, for all $x, y \in X_{0}$ and all 1quasigeodesics $\gamma_{x y}$ in $X$ joining $x, y, \operatorname{Hd}\left(\gamma_{x y}, c(x, y)\right) \leq R$.

Proof. Let $R=1+2 D_{0}$. Since path metric spaces are 1-quasi-path metric spaces, by Lemma 1.35 there is a $\left(K_{1.35}(1, R), \epsilon_{1.35}(1, R)\right.$-quasiisometry $\iota: Z \rightarrow X_{0} \subset X$ which is the identity on the vertex set of $Z$, where $Z$ is the full subgraph of the $R$-Rips graph of $X$ with the vertex set $X_{0}$. Also there is coarse inverse $\rho: X \rightarrow Z$ to $\iota$ which is the identity map when restricted to $X_{0}$ and and which is also a ( $K_{1.35}(1, R), \epsilon_{1.35}(1, R)$ )-quasiisometry. Let $k_{0}=K_{1.35}(1, R)+\epsilon_{1.35}(1, R)$. Then $\iota$ and $\rho$ are $k_{0}$-quasiisometries.

Now we shall verify that $Z$ satisfies the conditions of Proposition 1.62 by finding a suitable set of edge-paths joining each pair of vertices. Since hyperbolicity of pathmetric spaces is invariant under quasiisometry it will then follow that $X$ itself is uniformly hyperbolic. Suppose $x, y \in V(Z)$ and $\alpha:[0, l] \rightarrow X$ is the arc-length parametrization of the path $c(x, y)$. Let $n=\lfloor l\rfloor$. Consider the points $y_{i}=\alpha(i), 0 \leq i \leq n$ and $y_{n+1}=\alpha(l)=y$ if $l>n D_{0}$. For each $i$, there is a point $x_{i} \in X_{0}=V(Z)$ such that $d_{X}\left(y_{i}, x_{i}\right) \leq D_{0}$. Then

$$
d_{X}\left(x_{i}, x_{i+1}\right) \leq 1+2 D_{0}
$$

In particular, there is an edge in $Z$ joining $x_{i}, x_{i+1}$ for $0 \leq i \leq n$. This defines an edge-path $\beta=\beta(x, y)$ in $Z$ joining $x, y \in V(Z)$ and the length of $\beta(x, y)$ is at most $l+1$.

We take the subgraph $Y_{x y} \subset Z$ to be the image of the path $\beta(x, y)$. This is clearly a connected subgraph in $Z$. We now verify the conditions of Proposition 1.62 for this family of subgraphs.
(1) Suppose $x, y \in V(Z)$ with $d_{Z}(x, y) \leq 1$. This implies $d_{X}(x, y) \leq R$. Hence the length of $c(x, y)$ is at most $D_{1}$ by property (1). Thus the diameter of $Y_{x y}$ is at most $D_{1}+1$.
(2) If $V(\beta)$ denotes the vertex set $\left\{x_{i}\right\}$ of $\beta$ then we note that

$$
\operatorname{Hd}(c(x, y), V(\beta)) \leq 1+D_{0}
$$

Thus, clearly, for all $x, y, z \in V(Z)$, we have

$$
\beta_{x y} \subset N_{2+D_{0}+D_{2}}\left(\beta_{x z} \cup \beta_{z y}\right) .
$$

Thus if we take $h=\max \left\{D_{1}+1,2+D_{0}+D_{2}\right\}$, then $Z$ is $k_{1.62}(h)$-hyperbolic in the sense of Rips. Since $\rho: X \rightarrow Z$ is a $k_{0}$-quasiisometry, $X$ is $\delta=\delta_{1.55}\left(k_{1.62}(h), k_{0}\right)$-hyperbolic in the sense of Rips by Lemma 1.55.

For the second part of the corollary we set $m$ to be the least positive number satisfying $2 h\left(6+\log _{2}(m+2)\right) \leq m$. Let $x \neq y \in X_{0}$ be arbitrary points. Then by Theorem 1.62
any geodesic $\gamma_{x y}$ in $Z$ joining $x, y$ we have $\operatorname{Hd}\left(\gamma_{x y}, \beta_{x y}\right) \leq m-4 h$. Suppose $\alpha_{x y}$ is a 1quasigeodesic joining $x, y$ in $X$. Then clearly $\rho\left(\alpha_{x y}\right)$ is a $2 k_{0}$-quasigeodesic in $Z$. Thus, $\operatorname{Hd}\left(\gamma_{x y}, \rho\left(\alpha_{x y}\right)\right) \leq D_{1.53}\left(k_{1.62}(h), 2 k_{0}\right)$.

Hence, $\operatorname{Hd}\left(\beta_{x y}, \rho\left(\alpha_{x y}\right)\right) \leq m-4 h+D_{1.53}\left(k_{1.62}(h), 2 k_{0}\right)$ and, therefore,

$$
\operatorname{Hd}\left(V\left(\beta_{x y}\right), \rho\left(\alpha_{x y}\right)\right) \leq 1+m-4 h+D_{1.53}\left(k_{1.62}(h), 2 k_{0}\right)=R_{0} .
$$

But $V\left(\beta_{x y}\right)=\rho\left(V\left(\beta_{x y}\right)\right)$ since $\rho$ is the identity map when restricted to $X_{0}$. Hence,

$$
\operatorname{Hd}\left(\rho\left(V\left(\beta_{x y}\right)\right), \rho\left(\alpha_{x y}\right)\right) \leq R_{0}
$$

Since $\rho$ is a $k_{0}$-qi embedding we have $\operatorname{Hd}\left(V\left(\beta_{x y}\right), \alpha_{x y}\right) \leq k_{0}\left(R_{0}+k_{0}\right)$. The inequality $\operatorname{Hd}\left(c(x, y), V\left(\beta_{x y}\right)\right) \leq D_{0}+1$ implies $\operatorname{Hd}\left(c(x, y), \alpha_{x y}\right) \leq 1+D_{0}+k_{0}\left(R_{0}+k_{0}\right)$. Hence we may set $R=1+D_{0}+k_{0}\left(R_{0}+k_{0}\right)$.

Corollary 1.64. Given $D_{0} \geq 0, D>0$, and a coarse Lipschitz function $\eta: \mathbb{R}_{\geq 0} \rightarrow$ $\mathbb{R}_{\geq 0}$, there are $\delta=\delta_{1.64}\left(D_{0}, D, \eta\right) \geq 0$, and $K=K_{1.64}\left(D_{0}, D, \eta\right)<\infty$ such that:

Suppose $X$ is a path-metric space and $X_{0} \subset X$ is a $D_{0}$-net such that for each pair of points $x, y \in X_{0}$ we are given a rectifiable arc-length parametrized path $c(x, y)$ in $X$ joining $x, y$ with the following properties:

Property (1). For all $x, y \in X_{0}$ the path $c(x, y)$ is $\eta$-proper.
Property (2). For all $x, y, z \in X_{0}, c(x, y) \subset N_{D}(c(x, z) \cup c(z, y))$.
Then $X$ is $\delta$-hyperbolic in the sense of Rips and moreover, the paths $c(x, y)$ are $K$-quasigeodesics in $X$.

Proof. This follows from Corollary 1.63. Property 1 of Corollary 1.63 is verified with $D_{1}=\eta\left(2 D_{0}+1\right)$ and property 2 is verified with $D_{2}=D$. Thus we can take $\delta=$ $\delta_{1.64}\left(D_{0}, D, \eta\right)=\delta_{1.63}\left(D_{0}, \eta\left(2 D_{0}+1\right), D\right)$.

For the second part of the corollary suppose $\gamma_{x y}$ is an arc-length parametrized path in $X$ joining $x, y \in X_{0}$ such that length $\left(\gamma_{x y}\right) \leq 1+d(x, y)$. Then clearly it is a 1-quasigeodesic. By the second part of Corollary 1.63 we have

$$
\operatorname{Hd}\left(\gamma_{x y}, c(x, y)\right) \leq R_{1.63}\left(D_{0}, \eta\left(2 D_{0}+1\right), D\right)=R .
$$

Then, by Lemma 1.20, the paths $c(x, y)$ are $K_{1.20}(R, 1, \eta)$-quasigeodesics.
Remark 1.65. 1. Suppose that the assumption in Part (b) of this lemma holds. Then each path $c(x, x)$ has length $\leq D_{1}:=\eta(0)$, i.e. the condition (1) in Part (a) necessarily holds as well.
2. In the proofs of hyperbolicity of various spaces given in this books, based on Corollary 1.64, we first verify the uniform properness of the paths $c(x, y)$ and, frequently, also verify that they satisfy the Hausdorff fellow-traveling condition, before proving that (a2) holds.
3. In our proofs, instead of using arc-length parameterizations of the paths $c(x, y)$ we will be using some uniformly quasiisometric reparameterizations of these paths. Clearly, uniform properness of one implies uniform properness of the other.
4. We will refer to a family of paths $c$ as satisfying the assumptions of the corollary as a slim combing of $X$.

Lastly, we generalize this corollary to the case of discrete paths $c:[m, n] \cap \mathbb{Z} \rightarrow X$. We will be using the extension $\tilde{c}$ of maps $c$ to the real interval $[m, n]$ defined by sending the open interval $(i, i+1)$ to $c(i)$.

Corollary 1.66. Given $r>0, D_{0} \geq r, D_{1}>0$, and a function $\eta: \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}_{\geq 0}$ there are $\delta=\delta\left(D_{0}, D_{1}, \eta\right) \geq 0$, and $K=K\left(D_{0}, D_{1}, \eta\right)<\infty$ such that:
(a) Suppose $X$ is a r-quasi-path metric space and $X_{0} \subset X$ is a $D_{0}$-net such that for each pair of points $x, y \in X_{0}$ we are given a discrete $r$-path $c(x, y)$ in $X$ joining $x, y$ with the following properties:

Property (al). For all $D \geq 0$ and $x, y \in X_{0}$ with $d(x, y) \leq D$, the length of $c(x, y)$ in $X$ is at most $\eta(D)$.

Property (a2). For all $x, y, z \in X_{0}, c(x, y) \subset N_{D_{1}}(c(x, z) \cup c(z, y))$. Then $X$ is $\delta$-hyperbolic in the sense of Gromov.
(b) Moreover, if paths $c(x, y)$ are $\eta$-proper, then each map $\tilde{c}$ is a $K$-quasigeodesic in $X$.

Proof. By Corollary 1.33, there is a $(1, \epsilon)$-quasiisometry $\rho: X \rightarrow X^{\prime}$, where $X^{\prime}$ is a metric graph all whose each edges are of length $r$ and $\epsilon=\epsilon_{1.33}(r)$. Therefore, $X^{\prime}$ is a geodesic metric space. Now, define $X_{0}^{\prime}=\rho\left(X_{0}\right)$. We take any map $g: X_{0}^{\prime} \rightarrow X_{0}$ such that $x=\rho(g(x))$ for all $x \in X_{0}^{\prime}$. Then for all $x, y \in X_{0}^{\prime}$ we define a path $c^{\prime}(x, y)$ as follows. Let $c_{x y}: I_{x y} \cap \mathbb{Z} \rightarrow X$ be the parametrization of $c(g(x), g(y))$. For any two consecutive points $s, t \in I_{x y} \cap \mathbb{Z}$ we join $\rho \circ c_{x y}(s), \rho \circ c_{x y}(t)$ by a geodesic in $X^{\prime}$. Concatenation of these forms a path $c^{\prime}(x, y)$. We leave it to the reader to verify that the two properties of Corollary 1.64 hold for this family of paths in $X^{\prime}$. This implies that $X^{\prime}$ is uniformly Rips-hyperbolic and, hence, uniformly Gromov-hyperbolic by Lemma 1.45. Since $X$ is $(1, \epsilon)$-qi to $X^{\prime}$, it is also uniformly Gromov-hyperbolic by Lemma 1.40. The last part of the corollary follows from Lemma 1.20.

### 1.11. Hyperbolic cones

Suppose that $\left(Z, d_{Z}\right)$ is a path-metric space. In this section we define the hyperbolic cone $Z^{h}$ over $Z$. This definition will be used in Chapter 9 when discussing relatively hyperbolic spaces

As a topological space, $Z^{h}$ is the product $Z \times[1, \infty)$, where we identify $Z$ with $Z \times\{1\}$. We equip $Z^{h}$ with the length structure (imitating the description of the hyperbolic metric on horoballs in the real-hyperbolic space): Paths in this length structure are concatenation of vertical and horizontal path, with respect to the product decomposition of $Z^{h}$. Given two points $y_{1}, y_{2} \in[1, \infty)$, and $z \in Z$, we let the length of the interval between $\left(z, y_{1}\right),\left(z, y_{2}\right)$ in $\{z\} \times[1, \infty)$ equal $\left|\log \left(y_{2} / y_{1}\right)\right|$. We let the length of each horizontal path, contained in the "horosphere" $Z \times\{y\}$ equal $y^{-1}$ times the length of the corresponding path in $Z$. This length structure defines a path-metric on $Z^{h}$.

Remark 1.67. We refer the reader to the book of Roe [Roe03, 2.5] and the paper by Bowditch [Bow12] for alternative definitions of hyperbolic cones. For instance, Roe's construction works for general metric spaces $\left(Z, d_{Z}\right)$.

Proposition 1.68. The metric space $Z^{h}$ is $\delta$-hyperbolic for some uniform constant $\delta$.
Proof. We will describe a slim combing on $Z^{h}$. Each combing path will be a concatenation of at most two vertical paths and at most one horizontal path. Consider two points $x_{1}=\left(z_{1}, y_{1}\right), x_{2}=\left(z_{2}, y_{2}\right)$ in $Z^{h}$. If $z_{1}=z_{2}$ then the map $c\left(x_{1}, x_{2}\right)$ connecting $x_{1}$ to $x_{2}$ will be the unique vertical interval connecting these points. Suppose that $y_{1} \leq y_{2}$. Find the smallest $y \geq y_{2}$ such that

$$
y^{-1} d_{Z}\left(z_{1}, z_{2}\right) \leq 1
$$

Set $x_{i}^{\prime}:=\left(z_{i}, y\right), i=1,2$. Then $c\left(x_{1}, x_{2}\right)$ is the concatenation

$$
\left[x_{1} x_{1}^{\prime}\right] \star\left[x_{1}^{\prime} x_{2}^{\prime}\right] \star\left[x_{2}^{\prime} x_{2}\right],
$$

Figure 1. Combing of hyperbolic cone
where the first and the last segments are vertical intervals between $x_{i}, x_{i}^{\prime}, i=1,2$, and the middle segment $\left[x_{1}^{\prime} x_{2}^{\prime}\right]$ is any path in $Z \times\{t\}$ connecting $x_{1}^{\prime}$ to $x_{2}^{\prime}$ and having length $\leq 1$.

We now verify the slim combing properties of the paths $c$, as required by Corollary 1.64.

1. Uniform properness. We define two projections, $\pi_{1}: Z^{h} \rightarrow Z, \pi_{2}: Z^{h} \rightarrow[1, \infty)$,

$$
\pi_{1}((z, y))=z, \quad \pi_{2}((z, y))=y
$$

Then the composition $\log \circ \pi_{2}$ is 1 -Lipschitz, while the first projection has the property that if $\beta:[0,1] \rightarrow Z^{h}$ is a path such that $\pi_{2}(\beta([0,1])) \leq t_{0}$, then length $\left.\left(\pi_{1} \circ \beta\right)\right) \leq$ $\exp \left(t_{0}\right)$ length $(\beta)$. We will use these two observations to verify uniform properness of the paths $c$.

First, we note that it suffices to estimate from above the length of the path $c=c\left(x_{1}, x_{2}\right)$ in terms of the distance between $x_{1}=\left(z_{1}, y_{1}\right), x_{2}=\left(z_{2}, y_{2}\right)$.
a. Suppose, first that $y_{1} \neq y_{2}$. Then, since $\log \circ \pi_{2}$ is 1-Lipschitz,

$$
d\left(x_{1}, x_{2}\right) \geq d\left(\pi_{2}\left(x_{1}\right), \pi_{2}\left(x_{2}\right)\right) \geq \text { length }(c) .
$$

b. Thus, we only have to consider the case $y_{1}=y_{2}$. Furthermore, if

$$
y_{1}^{-1} d_{Z}\left(z_{1}, z_{2}\right) \leq 1
$$

then length $(c) \leq 1$ as well. Hence, without loss of generality, $y_{1}^{-1} d_{Z}\left(z_{1}, z_{2}\right) \geq 1$. Setting $D:=d_{Z}\left(z_{1}, z_{2}\right)$, we get $y=D$ and $c$ is the concatenation

$$
\left[x_{1} x_{1}^{\prime}\right] \star\left[x_{1}^{\prime} x_{2}^{\prime}\right] \star\left[x_{2}^{\prime} x_{2}\right],
$$

where $x_{i}^{\prime}:=\left(z_{i}, y\right), i=1,2$. The overall length of $c$ is

$$
\begin{equation*}
1+2 \log \left(y / y_{1}\right)=1+2 \log \left(D / y_{1}\right) . \tag{1.2}
\end{equation*}
$$

Let $\beta$ be a path connecting $x_{1}, x_{2}$. Define

$$
y_{0}:=\max \pi_{2} \circ \beta .
$$

Since $\log \circ \pi_{2}$ is 1-Lipschitz,

$$
\log \left(y_{0} / y_{1}\right) \leq \text { length }(\beta), \quad \log \left(y_{0}\right) \leq \text { length }(\beta)+\log \left(y_{1}\right) .
$$

Using the projection $\pi_{1}$, we see that

$$
D \leq \operatorname{length}\left(\pi_{1}(\beta)\right) \leq y_{0} \text { length }(\beta) \leq y_{0} \leq y_{1} \exp (\text { length }(\beta)) .
$$

Hence,

$$
\text { length }(c) \leq 1+2 \log \left(D / y_{1}\right) \leq 1+2 \text { length }(\beta)
$$

It follows that length $(c) \leq 1+2 d\left(x_{1}, x_{2}\right)$, as required.
2. Slim triangle condition. Consider three points $x_{i}=\left(z_{i}, y_{i}\right) \in Z^{h}, i=1,2,3$. We let $y_{i j}$ denote the maximum of $\pi_{2} \circ c\left(x_{i}, x_{i}\right), i \neq j$. After relabeling the points, we can assume that

$$
y_{12} \leq y_{23} \leq y_{31} .
$$

Define $x_{1}^{\prime}:=\left(z_{1}, y_{12}\right)$ and $x_{2}^{\prime}:=\left(z_{2}, y_{12}\right)$.
Replacing the points $x_{1}, x_{2}$, respectively, with $x_{1}^{\prime}=\left(z_{1}, y_{12}\right)$ and $x_{2}^{\prime}=\left(z_{2}, y_{12}\right)$ we see that the $c\left(x_{1}, x_{2}\right), c\left(x_{2}, x_{3}\right), c\left(x_{3}, x_{1}\right)$ is $\delta$-slim if and only if the triangle formed by the paths $c\left(x_{1}^{\prime}, x_{2}^{\prime}\right), c\left(x_{2}^{\prime}, x_{3}\right), c\left(x_{3}, x_{1}^{\prime}\right)$ is $\delta$-slim. Thus, without loss of generality, $x_{1}^{\prime}=x_{1}, x_{2}^{\prime}=x_{2}$ and the path $c\left(x_{1}, x_{2}\right)$ is horizontal, of length $\leq 1$. We claim that in this situation, the paths $c\left(x_{1}, x_{3}\right), c\left(x_{2}, x_{3}\right)$ are uniformly Hausdorff-close, which, of course, will imply the uniform slimness. Denoting

$$
x_{i}^{\prime \prime}:=\left(z_{i}, y_{23}\right), i=1,2,3
$$

we see that the parts $\operatorname{Hd}\left(c\left(x_{1}, x_{1}^{\prime \prime}\right), c\left(x_{2}, x_{2}^{\prime \prime}\right)\right) \leq 1$, while the parts between $x_{3}^{\prime \prime}$ and $x_{3}$ of $c\left(x_{1}, x_{3}\right), c\left(x_{2}, x_{3}\right)$ are equal. Thus, we need to bound the Hausdorff distance between $c\left(x_{1}^{\prime \prime}, x_{3}^{\prime \prime}\right), c\left(x_{2}^{\prime \prime}, x_{3}^{\prime \prime}\right)$.

We have:

$$
1 \geq y_{12}^{-1} d\left(z_{1}, z_{2}\right) \geq y_{23}^{-1} d\left(z_{1}, z_{2}\right)
$$

Applying the triangle inequality in $\left(Z, d_{Z}\right)$, we obtain

$$
2=1+1 \geq y_{23}^{-1}\left(d\left(z_{1}, z_{2}\right)+d\left(z_{2}, z_{3}\right)\right) \geq y_{23}^{-1} d\left(z_{3}, z_{1}\right)
$$

It follows that $y_{23} \leq y_{31} \leq 2 y_{23}$. Hence,

$$
d\left(x_{1}^{\prime \prime},\left(z_{1}, y_{31}\right)\right) \leq \log (2)
$$

It follows that the length of $c\left(x_{1}^{\prime \prime}, x_{3}^{\prime \prime}\right)$ is $\leq 1+2 \log (2)$, while the length of $c\left(x_{2}^{\prime \prime}, x_{3}^{\prime \prime}\right)$ is $\leq 1$. Clearly, these path are at the Hausdorff-distance $\leq 2+2 \log (2)$.

Remark 1.69. By Corollary 1.64, the slim combing paths $c\left(x_{1}, x_{2}\right)$ in $Z^{h}$ defined in this proof are $k$-quasigeodesics in $Z^{h}$ with the quasigeodesic constant $k$ independent of $Z$.

Lemma 1.70. Suppose that $z \in Z$ is within distance $\leq C$ from a segment $\left[z_{1} z_{2}\right]_{Z^{h}}$ with the end-points $z_{1}, z_{2}$ in $Z$. Then $d_{Z}\left(z,\left\{z_{1}, z_{2}\right\}\right) \leq C^{\prime}$, where $C^{\prime}$ depends only on $C$.

Proof. The combing path $c\left(z_{1}, z_{2}\right)$ is uniformly Hausdorff-close to the geodesic $\left[z_{1} z_{2}\right]_{Z^{h}}$. Hence, it suffices to prove the lemma with $\left[z_{1} z_{2}\right]_{Z^{h}}$ replaced by the combing path $c\left(z_{1}, z_{2}\right)$. Then the inequality $d_{Z^{h}}\left(z, c\left(z_{1}, z_{2}\right)\right) \leq C$ implies that

$$
d_{Z}\left(z,\left\{z_{1}, z_{2}\right\}\right) \leq 2 C+1
$$

Proposition 1.71. The inclusion map $Z \rightarrow Z^{h}$ is $\eta$-uniformly proper, where $\eta(t)=$ $a \exp (a t)$ and $a$ is a universal constant.

By the above remark, there is a universal constant $L$ such that for any two points $z_{1}, z_{2} \in Z$ the combing path $c=c\left(z_{1}, z_{2}\right)$ is an $L$-quasigeodesic in $Z^{h}$. By the equation (1.2), unless $D=d_{Z}\left(z_{1}, z_{2}\right) \leq 1$, the length of this path is $1+2 \log (D)$ since in our situation $y_{1}=1$. In the exceptional case when $D \leq 1$, the path $c$ is horizontal and has length $D$. Thus,

$$
d_{Z^{h}}\left(z_{1}, z_{2}\right) \geq L^{-1} \text { length }(c) \geq \min \left(2 L^{-1} \log (D), L^{-1} D\right)
$$

and, hence,

$$
D \leq \exp \left(\frac{1}{2} L d_{Z^{h}}\left(z_{1}, z_{2}\right)\right)+L d_{Z^{h}}\left(z_{1}, z_{2}\right) \leq a \exp \left(a d_{Z^{h}}\left(z_{1}, z_{2}\right)\right)
$$

for $a=\max \left(1, \frac{1}{2} L\right)$.

### 1.12. Geometry of hyperbolic triangles

Informally speaking, triangles in hyperbolic spaces resemble triangles in trees, i.e. tripods. The comparison map to trees makes this precise and allows one to reduce proofs of various statements about hyperbolic triangles to that of tripods in trees. Below, by a tree we mean a regular simplicial tree $T$ of valence $\geq 3$, equipped with the standard graphmetric. However, any real tree (a 0 -hyperbolic geodesic metric space) not isometric to an interval, will work just as well. For any three numbers $a_{1}, a_{2}, a_{3}$ satisfying the triangle inequalities $a_{i} \leq a_{j}+a_{k},\{i, j, k\}=\{1,2,3\}$, there exists a triangle $\Delta \subset T$ with the sidelengths $a_{1}, a_{2}, a_{3}$. Accordingly, for each triangle $\Delta=\Delta x_{1} x_{2} x_{3}$ in a metric space $X$, we define its comparison triangle

$$
\bar{\Delta}=\Delta \bar{x}_{1} \bar{x}_{2} \bar{x}_{3}
$$

in $T$, as a triangle in $T$ such that

$$
d\left(x_{i}, x_{j}\right)=d_{T}\left(\bar{x}_{i}, \bar{x}_{j}\right), \quad 1 \leq i, j \leq 3 .
$$

For each point $p$ in the side $x_{i} x_{j}$ of $\Delta$, define its comparison point $\bar{p} \in \bar{x}_{i} \bar{x}_{j} \subset \bar{\Delta}$ by the condition

$$
d\left(p, x_{i}\right)=d_{T}\left(\bar{p}, \bar{x}_{i}\right)
$$

Thus, we get the comparison map $\theta: \Delta \rightarrow \bar{\Delta}, \theta(p)=\bar{p}$, which restricts to an isometry on each side of $\Delta$. The internal points of $\Delta$ are the points of the $\theta$-preimage of the center of $\bar{\Delta}$. A triangle $\Delta$ is $\delta$-thin if and only if the diameters of all fibers of $\theta$ are $\leq \delta$. For each pair of points $p, q \in \Delta$ in a $\delta$-thin triangle $\Delta \subset X$, triangle inequalities imply:

$$
d(p, q)-2 \delta \leq d_{T}(\bar{p}, \bar{q}) \leq d(p, q)+\delta
$$

Thus, the map $\theta$ is a $(1,2 \delta)$-quasiisometry $\Delta \rightarrow \bar{\Delta}$ for $\delta$-thin triangles $\Delta \subset X$.
Definition 1.72. Let $(X, d)$ be a metric space. A point $p \in X$ is said to be a $C$-center of a geodesic triangle $\Delta$ if $p$ lies within distance $C$ from all three sides of the triangle. A 0 -center is simply called a center of $\Delta$. We will use this definition when $(X, d)$ is a tree, in which case the 0 -center is unique.

Note that if a geodesic metric space $X$ is $\delta$-hyperbolic, every geodesic triangle $\Delta$ in $X$ has a $\delta$-center, e.g. a point on one side of $\Delta$, within distance $\delta$ from the two other sides. The internal points of a $\delta$-thin triangle are mapped via the comparison map $\theta$ to the center of the comparison triangle in the tree and each internal points is a $\delta$-center of $\Delta$. It follows directly from the definition that every side of every $\delta$-slim triangle $\Delta$ contains a $\delta$-center of $\Delta$.

Definition 1.73. A $C$-tripod in $X$ is the union $T_{p}(x y z)$ of three geodesic segments $p x \cup p y \cup p z$, where $p$ is a $C$-center of a geodesic triangle $\Delta x y z$. The points $x, y, z$ are called the extremities of the tripod and the segments $p x, p y, p z$ are the legs of the tripod. If $X$ is a tree and $C=0$ then by a tripod in $X$ we mean a 0 -tripod and the center of a tripod means its 0 -center.

As noted above, if a triangle $\Delta=\Delta x y z$ is $\delta$-slim, then there exists a point $p \in x y$ such that the union $p x \cup p y \cup p z$ is a $\delta$-tripod.

The next lemma follows immediately from the definitions:
Lemma 1.74. If $X$ is $\delta$-hyperbolic in the sense of Rips, then each $C$-tripod $T_{p}(x y z) \subset X$ is $C+\delta$-Hausdorff close to the triangle $\Delta x y z$.

Lemma 1.75. If $X$ is $\delta$-hyperbolic in the sense of Rips, then for each $C$-tripod $T_{p}(x y z)$, the point $p$ is a $C+2 \delta$-center of every triangle $\Delta x^{\prime} y^{\prime} z^{\prime}$, where $x^{\prime} \in p x, y^{\prime} \in p y, z^{\prime} \in p z$.

Proof. Consider a point $u \in x y$ within distance $C$ from $p$. By the $2 \delta$-slimness of the quadrilateral $x x^{\prime} y^{\prime} y$, either there exists a point $u^{\prime} \in x^{\prime} y^{\prime}$ at distance $\leq 2 \delta$ from $u$, or there is a point $v \in x x^{\prime} \cup y y^{\prime}$ at distance $\leq \delta$ from $u$. In the latter case, for some $u^{\prime} \in\left\{x^{\prime}, y^{\prime}\right\}$, we get $d\left(p, u^{\prime}\right) \leq C+\delta$. Thus, in each case, there is $u^{\prime} \in x^{\prime} y^{\prime}$ within distance $C+2 \delta$ from $p$.

Lemma 1.76. Suppose that $X$ is a $\delta$-hyperbolic geodesic metric space. If $p, q$ are $C$ centers of the same geodesic triangle, then $d(p, q) \leq D_{1.76}(\delta, C)$.

Proof. We will use the comparison map $\theta: \Delta \rightarrow \bar{\Delta}$. Since $X$ is $\delta$-hyperbolic, the triangle $\Delta$ will be $6 \delta$-thin (Lemma 1.44) and, hence, $\theta: x \mapsto \bar{x}$ satisfies the inequalities

$$
d(a, b)-12 \delta \leq d_{T}(\bar{a}, \bar{b}) \leq d(a, b)+6 \delta
$$

$a, b \in \Delta$. We now prove the lemma. Let $p$ be a $C$-center of $\Delta$ and $p_{1}, p_{2}, p_{3}$ be the points on the sides of $\Delta$ within distance $C$ from $p$. Then $d\left(p_{i}, p_{j}\right) \leq 2 C, 1 \leq i<j \leq 3$. We will estimate the distances from the points $p_{i}$ to the internal points $c_{i}$ of $\Delta$, where we label the points so that $p_{i}, c_{i}$ lie on the same side of $\Delta$. Let $\bar{c} \in \bar{\Delta}$ denote the center of $\bar{\Delta}, \bar{c}=\theta\left(c_{i}\right)$, $i=1,2,3$. Then

$$
d_{T}\left(\theta\left(p_{i}\right), \theta\left(p_{j}\right)\right) \leq 2 C+6 \delta
$$

It is easy to see that all three points $\theta\left(p_{i}\right)$ cannot lie on the same leg of the tripod $\bar{\Delta}$, unless one of them equals to the center of $\bar{\Delta}$. Thus, there exists $i$ such that $d_{T}\left(\theta\left(p_{i}\right), \bar{c}\right) \leq$ $\frac{1}{2}(2 C+6 \delta)=C+3 \delta$. Since $\theta$ is an isometry on each side of $\Delta$, we then obtain

$$
d\left(p_{i}, c_{i}\right) \leq C+3 \delta
$$

and, hence, $d\left(p, c_{i}\right) \leq 2 C+3 \delta$ for one of the internal points of $\Delta$. Since the internal points are distance $\leq 6 \delta$ apart, we conclude that for any two $C$-centers $p, q$ of $\Delta$

$$
d(p, q) \leq D_{1.76}(\delta, C):=2 C+9 \delta
$$

Lemma 1.77. Suppose that $X$ is $\delta$-hyperbolic. For a geodesic triangle $\Delta x y z$ suppose that $x^{\prime} \in x z, y^{\prime} \in y z$ are equidistant from $z$ and satisfy the inequality $d\left(x^{\prime}, y^{\prime}\right)>2 \delta$. Then the path $x x^{\prime} \star x^{\prime} y^{\prime} \star y^{\prime} y$ is $C_{1.77}(\delta)$-quasigeodesic in $X$.

Proof. First we show that $x^{\prime} \in N_{\delta}(x y)$. By $\delta$-hyperbolicity of the $\Delta x y z, x^{\prime} \in N_{\delta}(x y \cup$ $y z$ ). If possible suppose $d\left(w, x^{\prime}\right) \leq \delta$ for some $w \in y z$. Then $\left|d(z, w)-d\left(x^{\prime}, w\right)\right| \leq d\left(w, x^{\prime}\right) \leq$ $\delta$. This implies $d\left(y^{\prime}, w\right) \leq \delta$, since $d\left(z, x^{\prime}\right)=d\left(z, y^{\prime}\right)$. It follows that $d\left(x^{\prime}, y^{\prime}\right) \leq d\left(w, x^{\prime}\right)+$ $d\left(w, y^{\prime}\right) \leq 2 \delta$, a contradiction. Hence, $x^{\prime} \in N_{\delta}(x y)$. Let $x^{\prime \prime} \in x y$ be any point with $d\left(x^{\prime}, x^{\prime \prime}\right) \leq \delta$.

Next we claim that $y^{\prime} \in N_{5 \delta}\left(x^{\prime \prime} y\right)$. Since the quadrilateral $\square x^{\prime} x^{\prime \prime} y z$ is $2 \delta$-slim,

$$
y^{\prime} \in N_{2 \delta}\left(x^{\prime} x^{\prime \prime} \cup x^{\prime \prime} y \cup x^{\prime} z\right)
$$

If $y^{\prime} \in N_{2 \delta}\left(x^{\prime} x^{\prime \prime}\right)$ then clearly $d\left(x^{\prime \prime}, y^{\prime}\right) \leq 3 \delta$. As in the previous paragraph, if $y^{\prime} \in N_{2 \delta}\left(x^{\prime} z\right)$ then $d\left(x^{\prime}, y^{\prime}\right) \leq 4 \delta$ and thus $d\left(y^{\prime}, x^{\prime \prime}\right) \leq 5 \delta$. If neither of these happen then $y^{\prime} \in N_{2 \delta}\left(x^{\prime \prime} y\right)$. This proves our claim. Let $y^{\prime \prime} \in x^{\prime \prime} y$ be any point such that $d\left(y^{\prime}, y^{\prime \prime}\right) \leq 5 \delta$.

Let $\alpha:[0, l] \rightarrow X$ be the arc-length parametrization of $x x^{\prime} * x^{\prime} y^{\prime} * y^{\prime} y$. Suppose $s, t \in[0, l]$ and $s<t$. Let $x_{1}=\alpha(s), y_{1}=\alpha(t)$. We already have $d\left(x_{1}, y_{1}\right) \leq t-s$.

If both $x_{1}, y_{1}$ are on the same segment then there is nothing to prove. So assume otherwise. Suppose $x_{1} \in x x^{\prime}$ and $y_{1} \in x^{\prime} y^{\prime}$. Since the quadrilateral $\square x^{\prime} y^{\prime} y^{\prime \prime} x^{\prime \prime}$ is $2 \delta$-slim, there is a point $y_{1}^{\prime} \in x^{\prime \prime} y^{\prime \prime}$ such that $d\left(y_{1}, y_{1}^{\prime}\right) \leq 7 \delta$. Also by the $\delta$-slimness of $\Delta x x^{\prime} x^{\prime \prime}$, there is a point $x_{1}^{\prime} \in x x^{\prime \prime}$ such that $d\left(x, x_{1}^{\prime}\right) \leq 2 \delta$. It follows that

$$
\begin{aligned}
& d\left(x_{1}, y_{1}\right) \geq d\left(x_{1}^{\prime}, y_{1}^{\prime}\right)-d\left(x_{1}, x_{1}^{\prime}\right)-d\left(y_{1}, y_{1}^{\prime}\right) \geq \\
& d\left(x_{1}^{\prime}, x^{\prime \prime}\right)+d\left(x^{\prime \prime}, y_{1}^{\prime}\right)-9 \delta \geq \\
& d\left(x_{1}, x^{\prime}\right)-d\left(x, x_{1}^{\prime}\right)-d\left(x^{\prime}, x^{\prime \prime}\right)+d\left(x^{\prime}, y_{1}\right)-d\left(x^{\prime}, x^{\prime \prime}\right)-d\left(y_{1}, y_{1}^{\prime}\right)-9 \delta \geq \\
& d\left(x_{1}, x^{\prime}\right)+d\left(x^{\prime}, y_{1}\right)-20 \delta=t-s-20 \delta .
\end{aligned}
$$

In the same way, if $x_{1} \in x^{\prime} y^{\prime}, y_{1} \in y^{\prime} y$ we have $d\left(x_{1}, y_{1}\right) \geq t-s-20 \delta$. Next suppose $x_{1} \in x x^{\prime}$ and $y_{1} \in y^{\prime} y$. Then there are points $x_{1}^{\prime} \in x x^{\prime \prime}$ and $y_{1}^{\prime} \in y^{\prime \prime} y$ such that $d\left(x_{1}, x_{1}^{\prime}\right) \leq 2 \delta$ and $d\left(y_{1}, y_{1}^{\prime}\right) \leq 6 \delta$ by the $\delta$-slimness of the triangles $\Delta x x^{\prime \prime} x^{\prime}$ and $\Delta y^{\prime} y^{\prime \prime} y$ respectively. It follows that

$$
\begin{aligned}
d\left(x_{1}, y_{1}\right) \geq d\left(x_{1}^{\prime}, y_{1}^{\prime}\right)-d\left(x_{1}, x_{1}^{\prime}\right)-d\left(y_{1}, y_{1}^{\prime}\right) \geq \\
d\left(x_{1}^{\prime}, x^{\prime \prime}\right)+d\left(x^{\prime \prime}, y^{\prime \prime}\right)+d\left(y^{\prime \prime}, y_{1}^{\prime}\right)-8 \delta \geq \\
d\left(x_{1}, x^{\prime}\right)-d\left(x_{1}, x_{1}^{\prime}\right)-d\left(x^{\prime}, x^{\prime \prime}\right)+d\left(x^{\prime}, y^{\prime}\right)-d\left(x^{\prime}, x^{\prime \prime}\right)- \\
d\left(y^{\prime}, y^{\prime \prime}\right)+d\left(y^{\prime}, y_{1}\right)-d\left(y^{\prime}, y^{\prime \prime}\right)-d\left(y_{1}, y_{1}^{\prime}\right)-8 \delta \geq \\
d\left(x_{1}, x^{\prime}\right)+d\left(x^{\prime}, y^{\prime}\right)+d\left(y^{\prime}, y_{1}\right)-28 \delta=t-s-28 \delta .
\end{aligned}
$$

Hence, the arc-length parametrization of $x x^{\prime} \star x^{\prime} y^{\prime} \star y^{\prime} y$ is a $(1,28 \delta)$-quasigeodesic. In particular, we can take $C_{1.77}(\delta)=1+28 \delta$.

As an application of the lemma we will prove that two geodesics $x z, z y$ either are uniformly close to each other on "long subintervals" $x^{\prime} z, y^{\prime} z$, or their concatenation $x z \star z y$ is a uniform quasigeodesic in $X$ :

Lemma 1.78. Suppose that $R \leq \min (d(x, z), d(y, z))$ is such that points $x^{\prime} \in x z, y^{\prime} \in y z$ at the distance $R$ from $z$ satisfy $d\left(x^{\prime}, y^{\prime}\right)>2 \delta$. Then the concatenation $x z \star z y$ is an $L_{1.78}(R, \delta)$-quasigeodesic in $X$.

Proof. According to the previous lemma, the concatenation $x x^{\prime} \star x^{\prime} y^{\prime} \star y^{\prime} y$ is a $C_{1.77}(\delta)$-quasigeodesic in $X$. We regard $x z \star z y, x x^{\prime} \star x^{\prime} y^{\prime} \star y^{\prime} y$ as paths $c, c^{\prime}$ on intervals $[0, T],\left[0, T^{\prime}\right]$, parameterized by arc-length and connecting $x$ to $y$, where $T=$ $d(x, z)+d(z, y)] \leq T^{\prime} \leq T+2 R$. Then for each $t \in[0, T]$

$$
d\left(c(t), c^{\prime}(t)\right) \leq 2 R .
$$

Since $c^{\prime}$ is a $C_{1.77}(\delta)$-quasigeodesic, Lemma follows.
The next lemma is a consequence of Lemma 1.24, but we will give a direct proof:
Lemma 1.79. Suppose that $\Delta x y z$ is a geodesic triangle in a $\delta$-hyperbolic space $X$ and $d(y, z) \leq C$. Then there is a monotonic map $f: x z \rightarrow x y$ such that $d(f, \mathrm{id}) \leq 2(\delta+C)$.

Proof. We define $f$ as follows.

1. Points $p \in x z$ such that $d(x, p) \leq \min (d(x, z), d(x, y))$, will be sent to $\bar{p} \in x y$ such that $d(x, \bar{p})=d(x, p)$.
2. Points $p$ such that $d(x, p) \geq d(x, y)$ will be all sent to $y$.

Thus, the map $f: x z \rightarrow x y$ is monotonic but possibly discontinuous at $z$. We next estimate the distances $d(p, f(p))$. Since $X$ is $\delta$-hyperbolic, there exists a point $p^{\prime} \in x z \cup y z$ within distance $\delta$ from $p$.

Case 1: $p^{\prime} \in x y$ and $d(x, p)<\min (d(x, y), d(x, z))$. Then by the triangle inequalities,

$$
d(x, p)-\delta \leq d\left(x, p^{\prime}\right) \leq d(x, p)+\delta
$$

In particular, $d\left(p^{\prime}, \bar{p}\right) \leq \delta$ and, thus, $d(p, f(p)) \leq 2 \delta$.
Case 2: $d(x, p) \geq \min (d(x, z), d(x, y))$, which implies that $d(p, z) \leq C, d(p, y) \leq 2 C$. Thus, $d(p, f(p)) \leq 2 C$.

Case 3. $p^{\prime} \in y z$ and $d(x, p)<\min (d(x, y), d(x, z))$. Since $p^{\prime} \in y z$ and $d(y, z) \leq C$, we get $d(p, y) \leq \delta+C$. By the same argument as in Case 1,

$$
d(x, \bar{p})-C-\delta \leq d(x, y) \leq d(x, \bar{p})+\delta+C,
$$

with the point $y$ playing the role of $p^{\prime}$ in Case 1 . Thus, $d(y, \bar{p}) \leq \delta+C$, which implies

$$
d(p, f(p)) \leq 2(\delta+C)
$$

We will apply this construction in the following situation. Let $\Delta=\Delta x_{1} x_{2} x_{3}$ be a geodesic triangle in $X, z$ be its $\delta$-center, $y \in x_{1} x_{2}$ a point within distance $\delta$ from $z$. We then use the maps $f_{1}: x_{1} z \rightarrow x_{1} y, f_{2}: x_{2} z \rightarrow x_{2} y$ as in the lemma. These maps combine to define a map $f: x_{1} z \cup z x_{2} \rightarrow x_{1} x_{2}$. We parameterize concatenation $\alpha=x_{1} z \star z x_{2}$ by its arc-length. Then the map $f$ is monotonic (with respect to the parameterization), fixes the endpoints of $\alpha$ and satisfies

$$
d(p, f(p)) \leq 4 \delta, p \in \alpha
$$

We, thus, obtain:
Corollary 1.80. Suppose that $z$ is a $\delta$-center of a geodesic triangle $\Delta=\Delta x_{1} x_{2} x_{3}$ in a $\delta$-hyperbolic space $X$. Then there exists a monotonic map

$$
f: x_{1} z \star z x_{2} \rightarrow x_{1} x_{2}
$$

such that $d(f, \mathrm{id}) \leq 4 \delta$.

### 1.13. Ideal boundaries

In the book we will be mostly working with Gromov's notion of ideal boundary (Gromov-boundary) $\partial_{\infty} Z$ of a space $Z$, which is hyperbolic in the sense of Gromov. The elements of $\partial_{\infty} Z$ are equivalence classes $\left[z_{n}\right]$ of Gromov-sequences $\left(z_{n}\right)$ in $Z$ (see e.g. [DK18, V0̈5]):

A sequence $\left(z_{n}\right)$ in $Z$ is called a Gromov-sequence if

$$
\lim _{m, n \rightarrow \infty}\left(z_{m} \cdot z_{n}\right)_{z}=\infty
$$

for some (equivalently, every) $z \in Z$.
Two Gromov-sequences $\left(w_{m}\right),\left(z_{n}\right)$ are equivalent if

$$
\lim _{m, n \rightarrow \infty}\left(w_{m} \cdot z_{n}\right)_{z}=\infty .
$$

One extends the definition of the Gromov-product to the elements $\xi, \zeta$ of the Gromovboundary (equivalence classes of Gromov-sequences) $\xi, \zeta$ by

$$
(\xi \cdot \zeta)_{z}:=\inf \liminf _{m, n \rightarrow \infty}\left(w_{m} . z_{n}\right)_{z},
$$

where the infimum is taken over all sequences $\left(w_{n}\right),\left(z_{n}\right)$ representing $\xi, \eta$. (Here we follow the definition in [CDP90, $\mathbf{A B C}^{+} \mathbf{9 1}, \mathbf{V 0 0 5}$ ], which differs (by $\leq 2 \delta$ ) from the one in [ $\mathbf{B H 9 9 ]}$ and [Gd90], where the supremum is taken instead of the infimum.)

Similarly, one defines

$$
(w \cdot \zeta)_{z}:=\inf \liminf _{n \rightarrow \infty}\left(w \cdot z_{n}\right)_{z}
$$

for $w \in Z, \zeta \in \partial_{\infty} Z$. One topologizes the space $\bar{Z}:=Z \cup \partial_{\infty} Z$ so that a neighborhood basis of $z \in \partial_{\infty} Z$ in $\bar{Z}$ is given by the subsets (with fixed $p \in Z$ )

$$
U_{z, \epsilon}=\left\{w \in Z \cup \partial_{\infty} Z:(z . w)_{p}<\epsilon\right\} .
$$

In particular, a sequence $\left(z_{n}\right)$ in $Z$ converges to $\zeta \in \partial_{\infty} Z$ if and only if $\left(z_{n}\right)$ is a Gromovsequence representing $\zeta$.

Definition 1.81. Suppose that $Z$ is a Gromov-hyperbolic metric space. We will use the notation $\partial_{\infty} Z$ for the Gromov-boundary of $Z$, equipped with the above topology. For a subset $Y \subset Z$, we will use the notation

$$
\partial_{\infty}(Y, Z)
$$

for the accumulation set of $Y$ in $\partial_{\infty} Z$, the relative ideal boundary of $Y$ in $Z$.
We also define $\partial_{\infty}^{(2)} Z \subset\left(\partial_{\infty} Z \times \partial_{\infty} Z\right) / \tau$, the set of unordered pairs of distinct elements of $\partial_{\infty} Z$ : The involution $\tau$ swaps the two factors of $\partial_{\infty} Z \times \partial_{\infty} Z$.

Another common definition of the visual boundary of a hyperbolic geodesic metric space $Z$ uses equivalence classes of geodesic rays in $Z$ : Two rays are equivalent if they are at finite Hausdorff distance from each other. The two definitions agree if $Z$ is a proper metric space, see e.g. [BH99, III.H.3]. For non-proper spaces one can also use quasigeodesic rays, see e.g. [BS00, Section 5], [V0̈5].

For our purpose, it suffices to observe that if $\gamma: \mathbb{R}_{+} \rightarrow Z$ is a quasigeodesic ray in a geodesic hyperbolic space $Z$, for each sequence $\left(t_{n}\right)$ in $\mathbb{R}_{+}$diverging to $\infty$, the sequence $\left(\gamma\left(t_{n}\right)\right)$ is a Gromov-sequence in $Z$, and any two such sequences are equivalent. Thus, $\gamma$ defines a point $\xi \in \partial_{\infty} Z$. We will say that $\gamma$ is asymptotic of $\xi$ and that $\gamma$ joins $p=\gamma(0)$ and $\xi$. We will use the notation $\gamma=p \xi$ if $\gamma$ is a geodesic ray joining $p$ and $\xi$. If $\gamma$ is a biinfinite quasigeodesic, then it defines two quasigeodesic rays $\gamma_{ \pm}$(the restrictions of $\gamma$ to $\mathbb{R}_{+}$and to $\mathbb{R}_{-}$) and these are asymptotic to points $\xi_{ \pm}$, also denoted $\gamma( \pm \infty)$. A hyperbolic space $Z$ is said to be a visibility space if any two distinct ideal boundary points are connected by a biinfinite geodesic. For instance, each proper geodesic hyperbolic space is a visibility space. Even if $Z$ is a non-proper geodesic metric space, each point in $X$ can be joined to each point in $\partial_{\infty} Z$ by a quasigeodesic ray and any two distinct points in $\partial_{\infty} Z$ are connected by a biinfinite quasigeodesic, see e.g. [BS00, Section 5].

A generalized geodesic triangle in a $\delta$-hyperbolic geodesic metric space $Z$ is defined by taking a triple of points $z_{1}, z_{2}, z_{3} \in \bar{Z}$ (such that no two ideal boundary points in this triple are equal) and connecting them by geodesics in $Z$, the sides of the triangle $\Delta z_{1} z_{2} z_{3}$. An ideal triangle is a generalized triangle with all three vertices in $\partial_{\infty} Z$.

The next lemma is an application of the slim triangle property in $Z$, cf. [DK18, section 11.11]:

Lemma 1.82 (Slim generalized triangle property). Suppose that $Z$ is a $\delta$-hyperbolic geodesic metric space. Then:

1. Every generalized geodesic triangle $\Delta$ in $Z$ with two non-ideal vertices is $2 \delta$-slim: Each side of $\Delta$ is contained in the $2 \delta$-neighborhood of the union of the two other sides.
2. Every generalized geodesic triangle $\Delta$ in $Z$ with one non-ideal vertex is $3 \delta$-slim.
3. Every ideal triangle in $Z$ is $4 \delta$-slim.

Proof. 1. Let $\Delta=\Delta x y \zeta$, where $x, y \in Z, \zeta \in \partial_{\infty} Z$. Take diverging sequences $p_{n} \in x \zeta$, $q_{n} \in y \zeta$, where $x \zeta, y \zeta$ are the infinite sides of $\Delta$, such that $d\left(p_{n}, q_{n}\right) \leq C$, where $C$ is a constant. Since the quadrilateral $x p_{n} q_{n} y$ is $2 \delta$-slim (Lemma 1.47), it follows that for each point $z \in y \zeta$, if $n$ is sufficiently large, then $z \in y q_{n}$ and, furthermore, $d\left(z, x p_{n} \cup x y\right) \leq$ $2 \delta$. (The point $z$ can be $2 \delta$-close to the side $p_{n} q_{n}$ only for finitely many values of $n$.) In particular, $z$ lies in the $2 \delta$-neighborhood of $x y \cup x \zeta$. The same argument proves that each point $z \in x y$ also lies in the $2 \delta$-neighborhood of $x y \cup x \zeta$.
2. Suppose that $\Delta=\Delta x \eta \zeta$, where $\eta, \zeta$ are in $\partial_{\infty} Z$ and $x \in Z$. As before, consider diverging sequences $p_{n} \in x \eta, q_{n} \in x \zeta$. Find points $p_{n}^{\prime} \in \eta \zeta, q_{n}^{\prime} \in \eta \zeta$ within distance $C$ from $p_{n}, q_{n}$ respectively. Since the pentagon with the vertices $x, p_{n}, p_{n}^{\prime}, q_{n}^{\prime} q_{n}$ is $3 \delta$-slim, it follows that each point $z \in x \zeta$ lies in the $3 \delta$-neighborhood of the union $\eta \zeta \cup x \eta$.
3. The proof for ideal triangles is similar (we use $4 \delta$-slimness of hexagons in $X$ ) and is left to the reader.

Lemma 1.83. Suppose that $Z$ is a $\delta$-hyperbolic geodesic metric space, $\gamma_{i}: \mathbb{R}_{+} \rightarrow Z, i=$ 1,2, are geodesic rays within finite Hausdorff distance from each other. Then there exist $T_{1}, T_{2}$ (depending on $\gamma_{1}, \gamma_{2}$ ) such that

$$
\operatorname{Hd}\left(\gamma_{1}\left(\left[T_{1}, \infty\right)\right), \gamma_{2}\left(\left[T_{2}, \infty\right)\right)\right) \leq 4 \delta
$$

and, moreover, $d\left(\gamma_{1}\left(T_{1}\right), \gamma_{2}\left(T_{2}\right)\right) \leq 2 \delta$.
Proof. Since the rays are at finite Hausdorff distance, $\gamma_{1}(\infty)=\gamma_{2}(\infty)=\xi$ for some $\xi \in \partial_{\infty} Z$. Set $p:=\gamma(0), D:=d\left(p_{1}, p_{2}\right)$. Consider the generalized geodesic triangle $\Delta$ in $Z$ with the vertices $p_{1}=\gamma_{1}(0), p_{2}=\gamma_{2}(0)$ and the third vertex at infinity, $\xi$. Then by the slim triangle property, every point $x_{i} \in \gamma_{i}\left(\mathbb{R}_{+}\right)$is within distance $2 \delta$ from $\gamma_{3-i}\left(\mathbb{R}_{+}\right) \cup p_{1} p_{2}, i=$ $1,2$.

Take $T_{1}:=D+2 \delta$. The triangle inequality implies that $x_{1}:=\gamma_{1}\left(T_{1}\right)$ is within distance $2 \delta$ from some point $x_{2}=\gamma_{2}\left(T_{2}\right)$. Since the generalized triangle with the vertices $x_{1}, x_{2}, \xi$ is $2 \delta$-slim, it follows that every point of $\gamma_{1}\left(\left[T_{1}, \infty\right)\right)$ is within distance $4 \delta$ from a point of $\gamma_{2}\left(\left[T_{2}, \infty\right)\right)$ and vice versa.

Corollary 1.84. Suppose that $c_{1}, c_{2}$ are $k$-quasigeodesic rays in $Z$ such that $c_{1}(\infty)=$ $c_{2}(\infty)$. Then there exist $T_{1}, T_{2}$ such that

$$
\operatorname{Hd}\left(\gamma_{1}\left(\left[T_{1}, \infty\right)\right), \gamma_{2}\left(\left[T_{2}, \infty\right)\right)\right) \leq 4 \delta+2 D_{1.53}(\delta, k)
$$

Moreover, $d\left(\gamma_{1}\left(T_{1}\right), \gamma_{2}\left(T_{2}\right)\right) \leq 2 \delta+2 D_{1.53}(\delta, k)$.
A similar result holds for biinfinite quasigeodesics:
Lemma 1.85. Suppose that $X$ is a $\delta$-hyperbolic space, $\alpha, \beta$ are biinfinite L-quasigeodesics in $X$ such that

$$
\xi_{ \pm}=\alpha( \pm \infty)=\beta( \pm \infty) \in \partial_{\infty} X
$$

Then $\operatorname{Hd}(\alpha, \beta) \leq D_{1.85}(L, \delta)$.
Proof. Using the above corollary, we find subrays $\alpha_{ \pm}$in $\alpha$ and $\beta_{ \pm}$in $\beta$ which are asymptotic to, respectively, $\xi_{ \pm}$, such that the respective initial points $x_{ \pm}$(of $\alpha_{ \pm}$) and $y_{ \pm}$(of $\beta_{ \pm}$) satisfy

$$
d\left(x_{ \pm}, y_{ \pm}\right) \leq r:=2 \delta+2 D_{1.53}(\delta, k) .
$$

Removing the above rays from the quasigeodesics $\alpha, \beta$, we are left with two finite quasigeodesic subsegments $\alpha_{0} \subset \alpha$ (between the points $x_{ \pm}$) and $\beta_{0} \subset \beta$ (between the points $y_{ \pm}$). Now, applying Lemma 1.54 to $\alpha_{0}, \beta_{0}$, we get:

$$
\operatorname{Hd}\left(\alpha_{0}, \beta_{0}\right) \leq D_{1.54}(\delta, L, r)
$$

Hence, taking $D_{1.85}(L, \delta): \max \left(r, D_{1.54}(\delta, L, r)\right)$, concludes the proof of the lemma.
Each qi embedding $f: X \rightarrow Y$ of geodesic hyperbolic spaces has an extension to a map of Gromov-boundaries, a topological embedding $\partial_{\infty} f: \partial_{\infty} X \rightarrow \partial_{\infty} Y$. The combined map

$$
f \cup \partial_{\infty} f: X \cup \partial_{\infty} X \rightarrow Y \cup \partial_{\infty} Y
$$

is continuous at each point of $\partial_{\infty} X$, see e.g. [DK18, Exercise 11.109]. In Chapter 8 we will discuss the existence of such an extension in the case of more general coarse Lipschitz maps of hyperbolic spaces.

### 1.14. Quasiconvex subsets

Definition 1.86 (Quasiconvex subset). Let $X$ be a geodesic metric space, $Y \subseteq X$ and let $\lambda \geq 0$. We say that $Y$ is $\lambda$-quasiconvex in $X$ if every geodesic with end-points in $Y$ is contained in the $\lambda$-neighborhood of $Y$. A subset $Y \subset X$ is said to be quasiconvex if it is $\lambda$-quasiconvex for some $\lambda \geq 0$.

This definition generalizes in the setting of path-metric spaces where $Y \subset X$ is $\lambda$ quasiconvex if there is a function $\eta: \mathbb{R}_{+} \rightarrow \mathbb{R}_{+}$converging to 0 as $\epsilon \rightarrow 0+$, such that each $\epsilon$-geodesic $\gamma \subset X$ with end-points in $Y$, satisfies

$$
\gamma \subset N_{\alpha+\eta(\epsilon)}(Y) .
$$

Convex subsets of, say, Hadamard spaces, have several characteristic properties such as:

- Intersections of convex subsets are again convex.
- The nearest-point projection to a nonempty closed convex subset is well-defined and 1-Lipschitz.
Below we discuss analogues of these properties for quasiconvex subsets of geodesic hyperbolic spaces.

The following two lemmata are straightforward and we omit the proofs:
Lemma 1.87. Every geodesic triangle in a $\delta$-hyperbolic geodesic metric space is $\delta$ quasiconvex.

Lemma 1.88. 1. Suppose that $A$ is a $\lambda$-quasiconvex subset of a $\delta$-hyperbolic space $X$. Then the $R$-neighborhood $N_{R}(A)$ is $(R+2 \delta+\lambda)$-quasiconvex in $X$.
2. Suppose that $A$ is a $\lambda$-quasiconvex subset of a $\delta$-hyperbolic space $X$ and $B \subset X$ is such that $\operatorname{Hd}(A, B) \leq R$. Then $B$ is $2 R+2 \delta+\lambda$-quasiconvex in $X$.

We next discuss the relation between the quasiconvexity and qi embeddings.
Lemma 1.89. If $A$ is a $\lambda$-quasiconvex subset of a geodesic hyperbolic metric space ( $X, d$ ), then:

1. The metric space $\left(N_{\lambda}(A), d\right)$ is a quasi-path metric space.
2. When we equip $N_{\lambda}(A)$ with the path-metric $d_{p}$ induced from $X$, the inclusion map $N_{\lambda}(A) \rightarrow X$ is a qi embedding.

Proof. If $\lambda=0$, then $(A, d)$ is actually a geodesic metric space isometrically embedded in $(X, d)$ and there is nothing to prove. Thus, we assume that $\lambda>0$.

1. Consider points $x, y \in N_{\lambda}(A)$ and $a \in A, b \in A$ be points within distance $\lambda$ from $x, y$ respectively. Let $\gamma=a b$ be a geodesic in $X$ contained in $N_{\lambda}(A)$. Then divide $\gamma$ into subsegments $x_{i} x_{i+1}, 1 \leq i \leq n-1$ of equal length $\leq \lambda$. Then the finite sequence

$$
x=x_{0}, a=x_{1}, x_{2}, \ldots, x_{n}=b, x_{n+1}=y
$$

is a $\lambda$-path connecting $x$ to $y$ and

$$
\sum_{i=0}^{n} d\left(x_{i}, x_{i+1}\right) \leq d(x, y)+4 \lambda
$$

2. By the same argument, for any two points $x, y \in N_{\lambda}(A)$,

$$
d_{p}(x, y) \leq d(a, b)+2 \lambda \leq d(x, y)+4 \lambda .
$$

Therefore, the inclusion $\operatorname{map}\left(N_{\lambda}(A), d_{p}\right) \rightarrow(X, d)$ is a $(1,4 \lambda)$-qi embedding.
Lemma 1.90. Suppose that $Y, X$ are geodesic metric spaces, $X$ is $\delta$-hyperbolic and $f: Y \rightarrow X$ is a $K$-qi embedding. Then $f(Y)$ is $\lambda_{1.90}(\delta, K)=D_{1.53}(\delta, K)$-quasiconvex in $X$.

Proof. For a geodesic $\gamma=y_{1} y_{2} \subset Y, f(\gamma)$ is a $K$-quasigeodesic in $X$ connecting $x_{i}=f\left(y_{i}\right), i=1,2$. Therefore, by Lemma 1.53,

$$
\operatorname{Hd}\left(f(\gamma), x_{1} x_{2}\right) \leq \lambda=D_{1.53}(\delta, K)=92 K^{2}(K+3 \delta)
$$

which implies that $x_{1} x_{2} \subset N_{\lambda}(f(Y))$, i.e. $f(Y)$ is $\lambda$-quasiconvex.
The following is a converse to Lemma 1.90:
Lemma 1.91. Suppose that $(X, d)$ is hyperbolic, $Y$ is a geodesic metric space and $f$ : $Y \rightarrow X$ is a uniformly proper map with quasiconvex image. Then $f$ is a qi embedding.

Proof. By Lemma 1.89, if $A:=f(Y)$ is $\lambda$-quasiconvex, then $\left(N_{\lambda}(A), d_{p}\right)$ is qi embedded in $X$. Since $f$ is uniformly proper, Lemma 1.17 then implies that $f: Y \rightarrow\left(N_{\lambda}(A), d_{p}\right)$ is a quasiisometry. Therefore, $f: Y \rightarrow X$ is a qi embedding as a composition of two qi embeddings.

### 1.15. Quasiconvex hulls

A common source of quasiconvex subsets in hyperbolic spaces is given by quasiconvex hulls which we discuss in this section.

Definition 1.92. For a subset $U$ of a geodesic metric space $X$ we define the quasiconvex hull $\operatorname{Hull}(U)$ as the union of all geodesics in $X$ connecting all pairs of points in $U$. The $\epsilon$-quasiconvex hull $\operatorname{Hull}_{\epsilon}(U)$ of $U$ in $X$ is defined as the closed $\epsilon$-neighborhood of the quasiconvex hull $\operatorname{Hull}(U)$. Thus, $c l(\operatorname{Hull}(U))=\operatorname{Hull}_{0}(U)$.

By the construction, if $U$ is $\lambda$-quasiconvex, then

$$
\begin{equation*}
\operatorname{Hull}_{\epsilon}(U) \subset N_{\epsilon+\lambda}(U) \tag{1.3}
\end{equation*}
$$

Lemma 1.93. If $X$ is a $\delta$-hyperbolic geodesic metric space, then the inclusion map $Y=\operatorname{Hull}_{\delta}(U) \rightarrow X$ is $a(1, \epsilon)$-quasiisometric embedding with $\epsilon=6 \delta$ and $Y$ equipped with the path-metric induced from $X$.

Proof. Suppose first that $y_{1}, y_{2} \in \operatorname{Hull}(U)$ belong to geodesics $a_{1} b_{1}, a_{2} b_{2}$ with $a_{i}, b_{i} \in$ $U, i=1,2$. Since $X$ is $\delta$-hyperbolic, by considering geodesic triangles $\Delta a_{1} b_{1} b_{2}, \Delta a_{1} a_{2} b_{2}$, we see that $y_{1}$ is within distance $\delta$ from a point $z_{1} \in a_{1} b_{1} \cup b_{1} b_{2}$. Similarly, $y_{2}$ is within distance $\delta$ from a point $z_{2} \in a_{1} b_{1} \cup a_{1} a_{2}$. If both $z_{1}, z_{2}$ belong to the same geodesic $a_{1} b_{2}$ then we connect $y_{1}, y_{2}$ by a path of length $d\left(z_{1}, z_{2}\right)+2 \delta$ in $Y$. Hence, $d_{Y}\left(y_{1}, y_{2}\right) \leq d_{X}\left(y_{1}, y_{2}\right)+4 \delta$. The cases when one of the points $z_{1}, z_{2}$ is on the geodesic $a_{1} b_{2}$ are similar and left to the reader.

Suppose that $z_{1} \in b_{1} b_{2}, z_{2} \in a_{1} a_{2}$. We then switch to the triangles $\Delta a_{1} a_{2} b_{1}, \Delta a_{1} b_{1} b_{2}$. Again, it suffices to consider the case when $y_{1}$ is within distance $\delta$ from $w_{1} \in a_{1} a_{2}$ or $y_{2}$ is within distance $\delta$ from $w_{2} \in b_{1} b_{2}$. But then we can connect $y_{1}, y_{2}$ by a path in $Y$ of length $\leq 2 \delta+d\left(w_{1}, z_{2}\right)$ or $\leq 2 \delta+d\left(z_{1}, w_{2}\right)$. Again, $d_{Y}\left(y_{1}, y_{2}\right) \leq d_{X}\left(y_{1}, y_{2}\right)+4 \delta$.

Lastly, any two points $x_{1}, x_{2} \in Y$ are within distance $\delta$ from $\operatorname{Hull}(U)$ and, therefore, for $\epsilon=6 \delta$,

$$
d_{Y}\left(x_{1}, x_{2}\right) \leq d_{X}\left(x_{1}, x_{2}\right)+\epsilon .
$$

Corollary 1.94. Suppose $X$ is a $\delta$-hyperbolic geodesic metric space, $U \subset X$ is a $\lambda$-quasiconvex subset and $R \geq \lambda+\delta$. Then the inclusion map $N_{R}(U) \rightarrow X$ is a $(1,6 \delta+R)$ quasiisometric embedding, where $N_{R}(U)$ equipped with the path-metric induced from $X$.

Lemma 1.95. Let $X$ be $\delta$-hyperbolic geodesic metric space; assume that $U, V \subset X$ are $\lambda$-quasiconvex subsets with nonempty intersection. Then:

1. For every $R \geq \lambda+\delta$ the subset

$$
Y=N_{R}(U \cup V) \subset X
$$

is $(R+\delta)$-quasiconvex.
2. Furthermore, for each $R \geq 2 \lambda+4 \delta$, the inclusion map $Y \rightarrow X$ is a $(1,6 \delta+R)$ quasiisometric embedding where we equip $Y$ with the path-metric induced from $X$.

Proof. 1. For $a \in U, b \in V, c \in U \cap V$ we have

$$
a b \subset N_{\delta}(a c \cup b c) \subset N_{\lambda+\delta}(U \cup V) \subset Y=N_{R}(U \cup V)
$$

For $x \in N_{R}(U), y \in N_{R}(V)$ there exist $a \in U, b \in V$ satisfying $x y \subset N_{R+\delta}(a b)$. Since $a b \subset Y$, we obtain $x y \subset N_{R+\delta}(Y)$, i.e. $Y$ is $(R+\delta)$-quasiconvex.
2. Observe that

$$
N_{R}(U \cup V)=N_{R-(\lambda+\delta)}\left(N_{\lambda+\delta}(U \cup V)\right) .
$$

Thus, the second part of the lemma follows from the first in combination with Corollary 1.94.

Lemma 1.96. Suppose that $X$ is a $\delta$-hyperbolic geodesic metric space. Then for every $Y \subset X, \operatorname{Hull}_{\epsilon}(Y)$ is $3 \delta+\epsilon$-quasiconvex in $X$.

Proof. Take $x_{1}, x_{2} \in \operatorname{Hull}_{\epsilon}(Y)$; these points are within distance $\epsilon$ from $y_{1}, y_{2} \in \operatorname{Hull}(Y)$. As in the proof of Lemma 1.93, there exist $z_{1}, z_{2}$ lying on a common geodesic $a_{1} a_{2}$ connecting points in $Y$, such that

$$
d\left(y_{i}, z_{i}\right) \leq 2 \delta, i=1,2
$$

Hence, $d\left(x_{i}, z_{i}\right) \leq \epsilon+2 \delta$, which implies that for $\lambda=3 \delta+\epsilon$,

$$
x_{1} x_{2} \subset N_{\lambda}\left(z_{1} z_{2}\right) \subset N_{\lambda}(\operatorname{Hull}(Y)) .
$$

### 1.16. Projections

We now discuss properties of quasiconvex subsets in hyperbolic metric spaces. For a complete metric space $(X, d)$, a closed subset $Y \subset X$ and a point $x \in X$, we will be using nearest point projections $\bar{x} \in Y$ of the point $x$ to the subset $Y$. We note that a nearest point projection always exists (but need not be unique).

Remark 1.97. The assumptions that $X$ is complete and $Y$ is closed are essentially irrelevant: If they fail, then instead of nearest-point projections $\bar{x} \in Y$ of $x \in X$, we can use $\epsilon$-nearest point projections, i.e. points $\bar{x} \in Y$ such that for all $y \in Y$,

$$
d(x, y) \geq d(x, \bar{x})-\epsilon
$$

Since we are interested in coarse-geometric aspects of metric spaces, such "almost" nearest point projections will work just as well. In what follows, we, therefore, will use the same fudge as for path-metric spaces: We will talk about nearest point projections without imposing the assumption that a subset is closed and the ambient space is complete.

Notation for nearest point projections: Suppose that $Y$ is a closed subset in a complete metric space $X$. We shall denote by $P_{X, Y}$ or $P_{Y}$ (when the choice of $X$ is clear) or sometimes simply by $P$ (when the choices of $X$ and $Y$ are clear) a nearest-point projection $X \rightarrow Y$. We will see below (Lemma 1.99) that in hyperbolic spaces, nearest-point projections to quasiconvex subsets are "coarsely well-defined," thus, justifying the notation.

Lemma 1.98. Suppose that $X$ is a geodesic metric space, $Y \subset X, x \in X$ and $\hat{x} \in Y$ is such that each geodesic $x y, y \in Y$, passes within distance $r$ from $\hat{x}$. Then $d(\bar{x}, \hat{x}) \leq 2 r$, where $\bar{x}=P_{Y}(x)$.

Proof. We take $y=\bar{x}$ and let $z \in x y$ be a point within distance $r$ form $\hat{x}$. Since $d(x, \hat{x}) \geq d(x, y)$, it follows that $r \geq d(z, \hat{x}) \geq d(z, y)$. Therefore, $d(\hat{x}, y) \leq 2 r$.

We now turn to quasiconvex subsets of hyperbolic spaces.
Lemma 1.99 (See e.g. Lemma 11.53 in [DK18]). For each $\lambda \geq 0$ there is a constant $L_{1.99}=L_{1.99}(\delta, \lambda)$ such that the following holds:

If $X$ is a $\delta$-hyperbolic metric space and $Y$ is a $\lambda$-quasiconvex subset, then the projection map $P=P_{X, Y}: X \rightarrow Y$ is coarsely $L_{1.99}(\delta, \lambda)$-Lipschitz, i.e. for all $x, y \in X$ we have $d_{X}(P(x), P(y)) \leq L_{1.99}(\delta, \lambda)\left(d_{X}(x, y)+1\right)$. In particular, $P$ is coarsely well-defined: For different choices $\bar{x}_{1}, \bar{x}_{2}$ of points in $Y$ nearest to $x$ we have $d_{X}(P(x), P(y)) \leq L_{1.99}(\delta, \lambda)$.

Remark 1.100. We will frequently use this lemma when $Y$ is a geodesic in $X$, in which case $\lambda=\delta$ and $d(P(x), P(y)) \leq d(x, y)+12 \delta$, i.e. $L_{1.99}(\delta, \delta)=12 \delta$, compare Lemma 1.120. In general:

$$
L_{1.99}(\delta, \lambda)=\max (2,2 \lambda+9 \delta)
$$

see Lemma 11.53 in [DK18].

The next lemma is a converse to Lemma 1.99:
Lemma 1.101. Suppose that a metric space $\left(X, d_{X}\right)$ is $\delta$-hyperbolic, $Y \subset X$ is a rectifiably connected subset (equipped with the induced path-metric $d_{Y}$ ) such that there exists a $k$-coarse-Lipschitz retraction

$$
P: X \rightarrow Y .
$$

Then $Y$ is $\lambda=\lambda_{1.101}(k, \delta)$-quasiconvex in $X$.

Proof. The inclusion map $i:\left(Y, d_{Y}\right) \rightarrow\left(X, d_{X}\right)$ is 1-Lipschitz. Combining this with the existence of the retraction $P$, we conclude that $i$ is a $k$-quasiisometric embedding. For each $\epsilon>0$ any two points $y_{1}, y_{2} \in Y$ can be connected by a path $\alpha$ whose length is $\leq$ $d_{Y}\left(y_{1}, y_{2}\right)+\epsilon$, in particular, $\alpha$ is $(1, \epsilon)$-quasigeodesic. We will take $\epsilon=1$. The composition $i \circ \alpha$ in $X$ is $L=k(1+\epsilon)$-quasigeodesic. By the Morse Lemma (Lemma 1.53), the image of $i \circ \alpha$ is within distance $\lambda=D_{1.53}(\delta, L)$ from a geodesic $\gamma=y_{1} y_{2}$ in $X$ connecting $y_{1}$ to $y_{2}$. Hence, $\gamma$ is contained in the $\lambda$-neighborhood of $Y$.

Lemma 1.102 below is a converse to Lemma 1.98 in the context of hyperbolic spaces; it will be used repeatedly in the book:

Lemma 1.102. Suppose that $X$ is $\delta$-hyperbolic geodesic metric space, $Y \subset X$ is a $\lambda$ quasiconvex subset of $X$. Let $\bar{x} \in Y$ be a nearest-point projection of $x \in X$ to $Y$ and let $y \in Y$ be an arbitrary point. Then:
(i) $\bar{x}$ lies within distance $\lambda+2 \delta$ from (any) geodesic $x y \subset X$.
(ii) $\operatorname{Hd}(x y, x \bar{x} \cup \bar{x} y) \leq \lambda+3 \delta$.
(iii) The concatenation $x \bar{x} \star \bar{x} y$ is a $2(\lambda+2 \delta)$-quasigeodesic.

Proof. (i) We consider a geodesic triangle $\Delta x \bar{x} y$. Since this triangle is $\delta$-slim, there exist points $z \in x y, z^{\prime} \in x \bar{x}, z^{\prime \prime} \in y \bar{x}$ such that $d\left(z, z^{\prime}\right) \leq \delta, d\left(z^{\prime}, z^{\prime \prime}\right) \leq \delta$. Then $d\left(z^{\prime \prime}, Y\right) \leq \lambda$. Since $\bar{x}$ is a nearest point to $x$ in $Y$, it follows that $d\left(z^{\prime}, \bar{x}\right) \leq \lambda+\delta$, hence, $d(\bar{x}, z) \leq \lambda+2 \delta$.
(ii) As in the proof above, let $z \in x y$ be such that $d(x, z) \leq \lambda+2 \delta$. Then by $\delta$ hyperbolicity of $X$, it is clear that $\operatorname{Hd}(\bar{x} y, z y) \leq \lambda+3 \delta$ and $\operatorname{Hd}(x \bar{x}, x z) \leq \lambda+3 \delta$. From these it follows that $\operatorname{Hd}(x y, x \bar{x} \cup \bar{x} y) \leq \lambda+3 \delta$.
(iii) Taking $z \in x y$ as above, we see that

$$
d(x, y) \leq d(x, \bar{x})+d(\bar{x}, y)+2(\lambda+2 \delta) .
$$

Hence, $x \bar{x} \star \bar{x} y$ is a $(1,2(\lambda+2 \delta))$-quasigeodesic.
Below are several corollaries of the lemma:
Corollary 1.103. If $Y$ is a geodesic in $X$, then $\bar{x}$ lies within distance $3 \delta$ from (any) geodesic xy $\subset X$. In particular, for each geodesic triangle $\Delta=\Delta x y z$ in $X$, the projection $P_{y z}(x)$ is a $3 \delta$-center of $\Delta$.

Corollary 1.104 (Almost nearest-point projection). Suppose that $X, Y$ are as above and $y \in Y$ satisfies

$$
d(x, y) \leq d(x, \bar{x})+C .
$$

Then $d(\bar{x}, y) \leq C+2 \lambda+4 \delta$.
Proof. Let $z \in x y$ be a point within distance $\lambda+2 \delta$ from $\bar{x}$ and let $D$ denote $d(y, z)$. Then

$$
d(x, \bar{x})+C-D \geq d(x, y)-D=d(x, z) \geq d(x, \bar{x})-(\lambda+2 \delta),
$$

which implies that $D \leq C+\lambda+2 \delta$. Hence, $d(\bar{x}, y) \leq d(\bar{x}, z)+d(y, z) \leq C+2 \lambda+4 \delta$.
Corollary 1.105. Let $U, V \subset X$ be a pair of closed $\lambda$-quasiconvex subsets such that $\operatorname{Hd}(U, V) \leq D$. Then $d\left(P_{U}, P_{V}\right) \leq D_{1.105}(\delta, \lambda, D)$.

Proof. Let $u \in U, v \in V$ denote $P_{X, U}(x)$ and $P_{X, V}(x)$ respectively. Since $\operatorname{Hd}(U, V) \leq D$, there exist points $u^{\prime} \in V, v^{\prime} \in U$ such that

$$
d\left(u, u^{\prime}\right) \leq D, \quad d\left(v, v^{\prime}\right) \leq D .
$$

Hence,

$$
d\left(x, u^{\prime}\right)-D \leq d(x, u) \leq d\left(x, v^{\prime}\right) \leq d(x, v)+D
$$

By Corollary 1.104, $d\left(v, u^{\prime}\right) \leq 2 D+2 \lambda+4 \delta$. Hence, $d(u, v) \leq D_{1.105}(\delta, \lambda, D):=3 D+2 \lambda+$ $4 \delta$.

Corollary 1.106. Suppose that $Y \subset X$ is a $\lambda$-quasiconvex subset of a $\delta$-hyperbolic space $X$ and $x, \hat{x}$ are points in $X, Y$ respectively connected by a geodesic $c=x \hat{x}$ such that:

There exists a function $R \mapsto \hat{R}$ satisfying $y \in Y, d(y, c) \leq R \Rightarrow d(y, \hat{x}) \leq \hat{R}$.
Then $d\left(\hat{x}, P_{Y}(x)\right) \leq \widehat{\lambda+2} \delta$.
Proof. Let $\bar{x}=P_{Y}(x)$. Then, by Lemma 1.102(1), $d(\bar{x}, c) \leq \lambda+2 \delta=: R$. It then follows that $d(\bar{x}, \hat{x}) \leq \hat{R}=\widehat{\lambda+2} \delta$.

Corollary 1.107. Suppose that $V \subset U \subset X$ are two $\lambda$-quasiconvex subsets of $X$. Then

$$
d\left(P_{X, V}, P_{U, V} \circ P_{X, U}\right) \leq C_{1.107}(\delta, \lambda) .
$$

Proof. The proof is by repeated use of Lemma 1.102. For $x \in X$ set $x_{1}:=P_{U}(x), x_{2}:=$ $P_{V}(x), x_{3}:=P_{V}\left(x_{1}\right)$. Consider the triangle $\Delta x x_{1} x_{2}$. By Lemma 1.102(i), there is a point $x_{1}^{\prime} \in x x_{2}$ such that $d\left(x_{1}, x_{1}^{\prime}\right) \leq \lambda+2 \delta$ because $x_{2} \in U$ and $x_{1}$ is a nearest point projection of $x$ to $U$. Now we note that $x_{2}$ is a nearest point projection of $x_{1}^{\prime}$ on $V$. Hence there is a point $x_{2}^{\prime} \in x_{1}^{\prime} x_{3}$ such that $d\left(x_{2}, x_{2}^{\prime}\right) \leq \lambda+2 \delta$. Since $d\left(x_{1}, x_{1}^{\prime}\right) \leq \lambda+2 \delta$ and the $\Delta x_{1} x_{1}^{\prime} x_{3}$ is $\delta$-slim, there is a point $x_{3}^{\prime} \in x_{1} x_{3}$ such that $d\left(x_{2}^{\prime}, x_{3}^{\prime}\right) \leq \lambda+3 \delta$. Hence,

$$
d\left(x_{2}, x_{3}^{\prime}\right) \leq d\left(x_{2}, x_{2}^{\prime}\right)+d\left(x_{2}^{\prime}, x_{3}^{\prime}\right) \leq 2 \lambda+5 \delta
$$

Finally, we note that $x_{3}$ is a nearest point projection of $x_{2}^{\prime}$ on $V$ too. Hence, $d\left(x_{3}^{\prime}, x_{3}\right) \leq$ $d\left(x_{3}^{\prime}, x_{2}\right) \leq 2 \lambda+5 \delta$. Thus

$$
d\left(x_{2}, x_{3}\right) \leq C_{1.107}(\delta, \lambda):=d\left(x_{2}, x_{3}^{\prime}\right)+d\left(x_{3}^{\prime}, x_{3}\right) \leq 4 \lambda+10 \delta .
$$

The following variation on this corollary will be used in the proof of Corollary 1.132 and Theorem 3.3:

Lemma 1.108. Suppose that $X$ is $\delta$-hyperbolic, $U, V \subset X$ are, respectively, $\lambda$ and $\mu$ quasiconvex subsets. Set $\epsilon:=\mu+2 \delta$. Then for every $r \geq r_{1.108}(\lambda, \mu, \delta)=\epsilon+\delta+\lambda$, if $W=N_{r}(U) \cap V$ is nonempty, then the distance between the restrictions to $V$ of the projections $P_{X, W}, P_{X, U}$, is at most $\epsilon+\delta+r$.

Proof. Take $x \in V$ and consider points $\bar{x}=P_{X, W}(x), \hat{x}:=P_{X, U}(x)$. Since $\bar{x} \in N_{r}(U)$, there exists a point $x^{\prime} \in U$ such that $d\left(x^{\prime}, \bar{x}\right) \leq r$. By Lemma 1.102, there exists a point $y \in x x^{\prime} \cap B(\hat{x}, \epsilon)$. Since the triangle $\Delta x x^{\prime} \bar{x}$ is $\delta$-slim, the point $y$ is within distance $\delta$ either from a point $z \in \bar{x} x^{\prime}$ or from a point $z \in \bar{x} x$. In the former case,

$$
d(\bar{x}, \hat{x}) \leq \epsilon+\delta+r,
$$

as claimed. Suppose, therefore, that $z \in \bar{x} x$. Since $V$ is $\lambda$-quasiconvex, there exists $w \in V$ within distance $\lambda$ from $z$. Thus,

$$
d(\hat{x}, w) \leq \epsilon+\delta+\lambda
$$

The assumption that $r \geq \epsilon+\delta+\lambda$ implies that $w \in N_{r}(U) \cap V=W$. In particular,

$$
d(x, w) \geq d(x, \bar{x})
$$

Setting $t=d(x, z), s=d(z, \bar{x})$, we obtain $d(x, \bar{x})=t+s$ and, hence,

$$
t+s=d(x, \bar{x}) \leq d(x, w) \leq t+\lambda
$$

It follows that $s \leq \lambda$ and, therefore, $d(\hat{x}, \bar{x}) \leq \epsilon+\delta+s \leq \epsilon+\delta+\lambda \leq r$. Thus, in both cases, $d(\bar{x}, \hat{x}) \leq \epsilon+\delta+r$.

Below is another variation on Corollary 1.107 and Lemma 1.102(iii):

Lemma 1.109. Let $X$ be a $\delta$-hyperbolic space, and let $Y_{1} \supset Y_{2} \supset \ldots \supset Y_{n}$ be a chain of $\lambda$-quasiconvex subsets of $X$. For a point $x \in X$ define inductively points $y_{1}=$ $P_{X, Y_{1}}(x), \ldots, y_{n}=P_{Y_{n-1}, Y_{n}}\left(y_{n-1}\right)$. Then:

1. The concatenation

$$
x y_{1} \star \ldots . . y_{n-1} y_{n}
$$

is an $L_{1.109}(\delta, \lambda, n)$-quasigeodesic in $X$.
2. $d_{X}\left(P_{X, Y_{n}}(x), x_{n}\right) \leq D_{1.109}(\delta, \lambda, n)$.

Proof. The proof is by induction on $n$. If $n=1$, there is nothing to prove. Suppose that the claim holds for $n-1$, we will prove it for $n$.

By Lemma 1.102(iii), the concatenation $x y_{1} \star y_{1} y_{n}$ is a $2(\lambda+2 \delta)$-quasigeodesic in $X$. By the induction hypothesis, the concatenation $y_{1} y_{2} \star \ldots \star y_{n-1} y_{n}$ is a $L(\delta, \lambda, n-1)$ quasigeodesic. Now, Part 1 follows from the stability of quasigeodesics in hyperbolic spaces.

Part 2 of the lemma follows from the inductive application of Corollary 1.107.
We conclude the section with two technical lemmata that will be used in Section 3.3.1. The lemmata generalize the obvious fact that if $Z \subset Y \subset X$ are inclusions of subsets in a metric space $X$ such that $Z$ is convex in $X$, then $Z$ is also convex in $Y$, while if $Z$ is convex in $Y$ and $Y$ is convex in $X$ then $Z$ is convex in $X$.

Lemma 1.110. Suppose that $Z \subset Y \subset X$ are inclusions of metric spaces such that $Y$ is a $\delta$-hyperbolic geodesic metric space, $X$ is a geodesic metric space, $Z \subset X$ is $\lambda$-quasiconvex, and the inclusion map $Y \rightarrow X$ is an L-quasiisometric embedding, where $\lambda \geq \frac{3}{2} \delta$. Then $Z \subset Y$ is $\lambda^{\prime}$-quasiconvex with $\lambda^{\prime}=1500(L \lambda)^{3}$.

Proof. Pick any pair of points $p, q \in Z$, let $p q$ be a geodesic in $X$ contained in $N_{\lambda}(Z)$, let $\gamma: I=[a, b] \rightarrow X$ be its arc-length parameterization. Pick a maximal finite sequence of 1 -separated points $x_{i}=\gamma\left(t_{i}\right)$ and project these points to a sequence $z_{i}=P_{Z}\left(x_{i}\right) \in Z$. Then the maps $\left[t_{i}, t_{i+1}\right) \rightarrow\left\{z_{i}\right\}$ define a $k=2 L \lambda$-quasigeodesic $\beta: I \rightarrow Z \subset Y$. Let $\beta^{*}$ denote a geodesic in $Y$ connecting $p$ to $q$. By Theorem 1.53,

$$
\operatorname{Hd}\left(\beta, \beta^{*}\right) \leq 92 k^{2}(k+3 \delta) \leq 92 \cdot 16(L \lambda)^{3} \leq 1500(L \lambda)^{3}
$$

Remark 1.111. One can give a faster proof of the lemma using the restriction to $Y$ of the coarse Lipschitz retraction $P_{X, Z}$ (and quoting Lemma 1.101), but we prefer to get an explicit estimate.

Lemma 1.112. Suppose that $Z \subset Y \subset X$ are inclusions of metric spaces such that $X, Y$ are geodesic metric spaces (with the path-metric on $Y$ is induced by that of $X$ ), $X, Y$ are $\delta_{1}$ and $\delta_{2}$-hyperbolic respectively, $Y$ is $\lambda_{1}$-quasiconvex in $X, Z \subset Y$ is $\lambda_{2}$-quasiconvex, then $Z$ is $\lambda_{1.112}\left(\lambda_{1}, \lambda_{2}, \delta_{1}, \delta_{2}\right)$-quasiconvex in $X$.

Proof. The projections $P_{1}=P_{X, Y}: X \rightarrow Y, P_{2}=P_{Y, Z}: Y \rightarrow Z$ are $L_{1.99}\left(\delta_{i}, \lambda_{i}\right)$-coarse Lipschitz retractions, $i=1,2$. Hence, their composition $P_{2} \circ P_{1}: X \rightarrow Z$ is an $k$-coarse Lipschitz retraction with

$$
k=L_{1.99}\left(\delta_{1}, \lambda_{1}\right) \cdot L_{1.99}\left(\delta_{2}, \lambda_{2}\right)
$$

Therefore, by Lemma 1.101, $Z \subset X$ is $\lambda$-quasiconvex for

$$
\lambda=\lambda_{1.101}\left(k, \delta_{1}\right) .
$$

### 1.17. Images and preimages of quasiconvex subsets under projections

In this section we discuss the extent to which images and preimages of projections of quasiconvex subsets to quasiconvex subsets are again quasiconvex.

Lemma 1.113. Let $\alpha=x y \subset X$ be a geodesic in a $\delta$-hyperbolic geodesic metric space, $Y \subset X$ a $\lambda$-quasiconvex subset and $\bar{x}=P_{Y}(x), \bar{y}=P_{Y}(y)$. Then $\bar{\alpha}=P_{Y}(\alpha)$ is $D_{1.113}(\delta, \lambda)$ Hausdorff close to the geodesic $\bar{x} \bar{y}$.

Proof. i. Take $z \in \alpha$. Then $z$ lies within distance $2 \delta$ from a point $w \in x \bar{x} \cup \bar{x} \bar{y} \cup \bar{y} y$. If $w \in \bar{x} \bar{y}$ then $d(z, Y)=d(z, \bar{z})\left(\bar{z}=P_{Y}(z)\right)$ satisfies $d(z, Y) \leq \lambda+2 \delta$. In particular, $d(\bar{z}, w) \leq$ $4 \delta+\lambda$. Suppose that $w \in x \bar{x}$. Then, $d(w, Y)=d(w, \bar{x})$ and, without loss of generality, $P_{Y}(w)=\bar{x}$. Lemma 1.99 implies that $d(P(z), \bar{x})=d(P(z), P(w)) \leq(2 \delta+1) L_{1.99}(\delta, \lambda)$. The case $w \in y \bar{y}$ is handled by relabelling $x$ and $y$. To conclude:

$$
\bar{\alpha} \subset N_{D}(\bar{x} \bar{y}), \quad D=\max \left((2 \delta+1) L_{1.99}(\delta, \lambda), 4 \delta+\lambda\right)
$$

ii. Consider a point $z \in \bar{x} \bar{y}$. The point $z$ is within distance $2 \delta$ from some $w \in x y \cup x \bar{x} \cup y \bar{y} \overline{\text {. }}$ If $w \in x y$ then $d\left(w, P_{Y}(w)\right) \leq 2 \delta+\lambda$ and, hence, $d(z, P(w)) \leq 4 \delta+\lambda$. Suppose that $w \in x \bar{x}$. Then $d(z, \bar{x}) \leq 2 \delta$. Similarly in case $w \in y \bar{y}$ we have $d(z, \bar{y}) \leq 2 \delta$. Hence, in either case, we have $d(z, \bar{\alpha}) \leq 2 \delta+\lambda \leq D$.

To conclude, for

$$
D=D_{1.113}(\delta, \lambda):=\max \left((2 \delta+1) L_{1.99}(\delta, \lambda), 4 \delta+\lambda\right)
$$

the geodesic $\bar{x} \bar{y}$ and the set $\bar{\alpha}$ are $D$-Hausdorff close.
Corollary 1.114. If $\operatorname{diam}\{\bar{x}, \bar{y}\} \leq D$ then $\operatorname{diam}(\bar{\alpha}) \leq 2 D_{1.113}(\delta, \lambda)+D$.
Remark 1.115. If $\delta \geq 1$, then

$$
D_{1.113}(\delta, \lambda) \leq 3 \delta(2 \lambda+9 \delta)
$$

Corollary 1.116. Let $X$ be a $\delta$-hyperbolic space, $Y \subset X$ a $\lambda$-quasiconvex subset and $\gamma \subset X$ be a K-quasigeodesic connecting points $x$ and $y$ and $P=P_{X, Y}$. Then $P(\gamma)$ is $C_{1.116}(\delta, \lambda, K)$-Hausdorff close to the geodesic segment $P(x) P(y)$.

Proof. This corollary follows from the Morse Lemma, Lemmata 1.99 and 1.117.
As another application of the lemma, we obtain:
Lemma 1.117. Suppose that $Y, Z$ are $\lambda_{Y}, \lambda_{Z}$-quasiconvex subsets respectively in a $\delta$ hyperbolic space $X$. Then the projection $P_{Y}(Z)$ is $D_{1.117}\left(\delta, \lambda_{Y}, \lambda_{Z}\right)$-quasiconvex in $X$.

Proof. Take points $y_{i}=P_{Y}\left(z_{i}\right), z_{i} \in Z, y_{i} \in Y, i=1,2$. By Lemma 1.113,

$$
\operatorname{Hd}\left(y_{1} y_{2}, P_{Y}\left(z_{1} z_{2}\right)\right) \leq D_{1.113}\left(\delta, \lambda_{Y}\right)
$$

Thus, for every $y \in y_{1} y_{2}$ there exists $x \in z_{1} z_{2}$ such that $d\left(y, P_{Y}(x)\right) \leq D_{1.113}\left(\delta, \lambda_{Y}\right)$. Since $Z$ is $\lambda_{Z}$-quasiconvex in $X$, there exists $z \in Z$ such that $d(x, z) \leq \lambda_{Z}$. By Lemma 1.99,

$$
d\left(P_{Y}(x), P_{Y}(z)\right) \leq\left(\lambda_{Z}+1\right) L_{1.99}\left(\delta, \lambda_{Y}\right)
$$

Putting together these inequalities, we obtain:

$$
\begin{aligned}
d\left(y, P_{Y}(Z)\right) \leq & d\left(y, P_{Y}(z)\right) \leq D_{1.117}\left(\delta, \lambda_{Y}, \lambda_{Z}\right):= \\
& \left(\lambda_{Z}+1\right) L_{1.99}\left(\delta, \lambda_{Y}\right)+D_{1.113}\left(\delta, \lambda_{Y}\right. \text { Ф }
\end{aligned}
$$

Remark 1.118. If $\delta \geq 1, \lambda \geq 1$ then

$$
D_{1.117}(\delta, \lambda, \lambda) \leq(2 \lambda+3 \delta)(2 \lambda+9 \delta)
$$

Thus, projections (to uniformly quasiconvex subsets) in hyperbolic spaces send uniformly quasiconvex subsets to uniformly quasiconvex subsets. The next lemma, which we add only for the completeness of the picture and which is not used elsewhere otherwise, establishes a similar statement for preimages. We need to warn the reader that preimages of quasiconvex subsets under projections need not be quasiconvex, the true statement is more subtle.

Lemma 1.119. Suppose that $X$ is geodesic, $\delta$-hyperbolic, $Y, Z$ are $\lambda_{Y}, \lambda_{Z}$-quasiconvex subsets in $X$ respectively, such that $Z \subset Y$. Then

$$
\operatorname{Hull}\left(P_{Y}^{-1}(Z)\right) \subset P_{Y}^{-1}\left(N_{D}(Z)\right)
$$

for some $D=D_{1.119}\left(\delta, \lambda_{Y}, \lambda_{Z}\right)$.
Proof. Take two points $x, y \in P_{Y}^{-1}(Z)$ and a geodesic $\alpha=x y \subset X$ connecting these points. Then, for $\bar{x}=P_{Y}(x), \bar{y}=P_{Y}(y)$, by Lemma 1.113, $P_{Y}(\alpha)$ is $D_{1.113}\left(\delta, \lambda_{Y}\right)$-Hausdorff close to the segment $\beta=\bar{x} \bar{y}$. Since $\bar{x}, \bar{y}$ are in $Z$ and $Z$ is $\lambda_{Z}$-quasiconvex in $X, \beta \subset N_{\lambda_{Z}}(Z)$. Thus,

$$
\alpha \subset P_{Y}^{-1}\left(N_{D}(Z)\right), \quad D=D_{1.119}\left(\delta, \lambda_{Y}, \lambda_{Z}\right)=D_{1.113}\left(\delta, \lambda_{Y}\right)+\lambda_{Z}
$$

For a pair of $\lambda$-quasiconvex subsets $U, V$ in a hyperbolic space $X$ there is a basic dichotomy: Either $P_{U}(V)$ has uniformly bounded diameter (in terms of $\lambda$ and $\delta$ ) or it is uniformly close to a quasiconvex subset of $V$. We will discuss this and related issues in more detail in Sections 1.19 and 1.21; for now, we prove this statement in the context of projections of geodesics to geodesics:

Lemma 1.120. For any $\delta \geq 0$ and $\lambda \geq 0$ there is are constants $D=D_{1.120}(\delta, \lambda)$ $R=R_{1.120}(\delta, \lambda)$ such that the following holds:

1. Suppose $X$ is a $\delta$-hyperbolic geodesic metric space and $Y \subset X$ is $\lambda$-quasiconvex. Let $x, y \in X$ and let $\bar{x}, \bar{y} \in Y$ be respectively their nearest-point projections to $Y$. If $d(\bar{x}, \bar{y}) \geq D$ then $\bar{x} \bar{y} \subset N_{R}(x y)$. One can take $D=2 \lambda+7 \delta$ and $R=\lambda+5 \delta$.
2. When $Y$ is a geodesic, $\lambda=\delta$ and we can take: $D_{1.120}(\delta, \delta)=8 \delta, R_{1.120}(\delta, \delta)=6 \delta$.

Proof. We prove Part (1) and leave computations in Part (2) (as a special case) to the reader. By Lemma $1.102(\mathrm{i})$ there is a point $z \in x \bar{y}$ such that $d(\bar{x}, z) \leq \lambda+2 \delta$. Now we consider the geodesic triangle $\Delta x y \bar{y}$. Then $z \in N_{\delta}(x y \cup y \bar{y})$. Suppose $z \in N_{\delta}(y \bar{y})$ and let $w \in y \bar{y}$ such that $d(z, w) \leq \delta$. Then $d(w, \bar{x}) \leq \lambda+3 \delta$. Since $\bar{y}$ is a nearest point of $Y$ from $w$ it follows that $d(w, \bar{y}) \leq \lambda+3 \delta$. Thus it follows that $d(\bar{x}, \bar{y}) \leq 2 \lambda+6 \delta$. Hence, if $d(\bar{x}, \bar{y}) \geq \delta+2 \lambda+6 \delta$ then $\bar{x}, \bar{y} \in N_{\lambda+3 \delta}(x y)$. Since geodesic quadrilaterals in $X$ are $2 \delta-$ slim, in that case it follows that $\bar{x} \bar{y} \subset N_{\lambda+5 \delta}(x y)$. Hence, we may take $D=2 \lambda+7 \delta$ and $R=\lambda+5 \delta$.

### 1.18. Modified projection

In Section 5.1 we will need a minor modification of the projection $P_{X, Y}$ to quasiconvex subsets $Y \subset X$ in the setting when $Y=T=T_{p}(x y z)$ is a $C$-tripod and also in the setting of quasigeodesic tripods.

Definition 1.121. Suppose that $T$ is a tripod as above in a $\delta$-hyperbolic geodesic space $X$. For a subset $U \subset X$, we define its modified projection $\bar{P}_{X, T}(U)=\bar{P}_{T}(U) \subset T$ as

$$
\begin{equation*}
\bar{P}_{T}(U)=\operatorname{Hull}_{0}\left(P_{T}(U)\right), \tag{1.4}
\end{equation*}
$$

where the (closed) hull is taken with respect to the intrinsic path-metric of $T$.

If the nearest-point projection were continuous and $U$ were compact, then, of course, $\bar{P}_{T}(U)=P_{T}(U)$.

Lemma 1.122. Suppose that $U$ is a $\lambda$-quasiconvex subset of a $\delta$-hyperbolic space $X$, $T=T_{p}(x y z) \subset X$ is a C-tripod. Then

$$
\operatorname{Hd}_{X}\left(P_{T}(U), \bar{P}_{T}(U)\right) \leq C_{1.122}(\delta, \lambda, C)=D_{1.117}(\delta, \delta, \lambda)+C+3 \delta
$$

Proof. First of all, each tripod $T \subset X$ is $\delta$-quasiconvex. Therefore, according to Lemma 1.117, the projection $P_{T}(U)$ is a $\lambda^{\prime}=D_{1.117}(\delta, \delta, \lambda)$-quasiconvex subset of $X$. Hence, for points $x^{\prime} \in x p, y^{\prime} \in y p$ which belong to $P_{T}(U)$, the segment $x^{\prime} y^{\prime} \subset X$ is contained in the $\lambda^{\prime}$-neighborhood of $P_{T}(U)$. Since $p$ is a $C+2 \delta$-center of the tripod $T_{p}\left(x^{\prime} y^{\prime} z\right)$ (Lemma 1.75), the geodesic segment $\gamma \subset T$ connecting $x^{\prime}$ to $y^{\prime}$ is $C+3 \delta$-Hausdorff close to $x^{\prime} y^{\prime}$. Thus, each point $u \in \gamma$ is within distance $C+3 \delta$ from some $u^{\prime} \in x^{\prime} y^{\prime}$ and, by the $\lambda^{\prime \prime}$-quasiconvexity of $P_{T}(U)$, there exists $v \in P_{T}(U)$ such that $d\left(v, u^{\prime}\right) \leq \lambda^{\prime}$. By the triangle inequality, $d(u, v) \leq \lambda^{\prime}+C+3 \delta$. Thus, $\bar{P}_{T}(U) \subset N_{\lambda^{\prime}+C+3 \delta}\left(P_{T}(U)\right)$. Since $P_{T}(U) \subset \bar{P}_{T}(U)$, lemma follows.

Remark 1.123. Assuming that $\delta \geq 1$, we can take:

$$
\begin{array}{r}
C_{1.122}(\delta, \lambda, C)=C+3 \delta+\left(L_{1.99}(\delta, \delta)+1\right) \lambda+D_{1.113}(\delta, \delta) \leq \\
C+3 \delta+(12 \delta+1) \lambda+3 \delta(2 \lambda+9 \delta) \leq C+30 \delta^{2}+19 \delta \lambda
\end{array}
$$

Remark 1.124. As a special case, we will use the modified projection when the tripod $T$ is a single geodesic segment and $U$ is also a geodesic segment. The estimate on the Hausdorff-distance in this situation is better; we leave it to the reader to verify (analogously to the proof of Lemma 1.120) that

$$
C_{1.122}(\delta, \delta, 0)=4 \delta
$$

This estimate will be used in Section 5.2.
We will need a generalization of $\bar{P}$ and the lemma in the following setting: We let $Y$ be a union of three rectifiable arcs $\alpha \cup \beta \cup \gamma$ in $X$, connecting points $x, y, z$ in $X$ to a certain point $p \in X$ and parameterized by their arc-length. Thus, $Y$, equipped with its intrinsic path-metric $d_{Y}$, is an abstract tripod. We assume that the inclusion map $\left(Y, d_{Y}\right) \rightarrow X$ is a $K$-qi embedding. Note that if $\alpha, \beta, \gamma$ are all geodesics in $X$ and $Y$ is a $C$-tripod $T$, then the inclusion map $\left(T, d_{T}\right) \rightarrow X$ is a $4 \delta$-qi embedding. As before, for $U \subset X$ we define $\bar{P}_{Y}(U)$ as the closed convex hull of $P_{Y}(U)$ with respect to the metric $d_{Y}$. The next lemma follows from the fact that $Y$ is uniformly Hausdorff-close to the geodesic tripod $T=T_{p}(x y z)$; we leave a proof of the reader:

Lemma 1.125. Suppose that $U$ is a $\lambda$-quasiconvex subset of a $\delta$-hyperbolic space $X$. Then

$$
\operatorname{Hd}_{X}\left(P_{T}(U), \bar{P}_{T}(U)\right) \leq C_{1.125}(\delta, \lambda, K)
$$

### 1.19. Projections and coarse intersections

A basic fact of convex geometry is that intersections of convex subsets are again convex. In the context of quasiconvex subsets $U, V$ of a hyperbolic space, one needs to modify the notion of intersection. The most esthetically pleasing way to do so is to intersect $R$-neighborhoods of $U$ and $V$. However, most useful for us will be asymmetric coarse intersections $N_{R}(U) \cap V$. In this section we discuss these in conjunction with the projections $P_{U}(V)$ and $P_{V}(U)$.

Lemma 1.126 (Coarse intersections with quasiconvex subsets are quasiconvex). Suppose that $Y_{i} \subset X$ are $\lambda_{i}$-quasiconvex subsets in a $\delta$-hyperbolic space $X, i=1,2$. Then for every $\epsilon \geq \lambda_{1}+\lambda_{2}+2 \delta$, the intersection

$$
Y=N_{\epsilon}\left(Y_{1}\right) \cap Y_{2}
$$

is $\lambda_{1.126}(\epsilon, \delta)$-quasiconvex, with $\lambda_{1.126}=\epsilon+2 \delta$.
Proof. Take two points $x, y \in Y$ and let $x_{1}, y_{2} \in Y_{1}$, be points within distance $\epsilon$ from $x, y$ respectively. In view of the $2 \delta$-slimness of quadrilaterals in $X$, for each $z \in x y$ either $d\left(z, x_{1} y_{1}\right) \leq 2 \delta$ or $d(z, x) \leq 2 \delta+\epsilon$ or $d(z, y) \leq 2 \delta+\epsilon$. In the last two cases, $z \in N_{2 \delta+\epsilon}(Y)$. Suppose, therefore, that $d\left(z, x_{1} y_{1}\right) \leq 2 \delta$. By the $\lambda_{i}$-quasiconvexity of $Y_{i}$, there exist points $z_{i} \in Y_{i}$, such that $d\left(z, z_{1}\right) \leq \lambda_{1}+2 \delta$ and $d\left(z, z_{2}\right) \leq \lambda_{2}$. In particular, $d\left(z_{1}, z_{2}\right) \leq \lambda_{1}+\lambda_{2}+2 \delta \leq$ $\epsilon$, i.e. $z_{2} \in Y$. Since

$$
d\left(z, z_{2}\right) \leq \lambda_{2} \leq \epsilon+2 \delta,
$$

we conclude that $Y$ is $(\epsilon+2 \delta)$-quasiconvex.
The next lemma will be used in the proof of Theorem 3.3:
Lemma 1.127. Define the function

$$
R^{\prime}:=R_{1.127}(R, \lambda, \delta)=2 \lambda+3 \delta+R .
$$

Let $U_{1}, U_{2}$ be $\lambda$-quasiconvex subsets of a $\delta$-hyperbolic space $X$ such that $d\left(U_{1}, U_{2}\right) \leq R$. Then

$$
P_{U_{2}}\left(U_{1}\right) \subset N_{R^{\prime}}\left(U_{1}\right) \cap U_{2}
$$

and

$$
\operatorname{Hd}\left(P_{U_{1}}\left(U_{2}\right), P_{U_{2}}\left(U_{1}\right)\right) \leq R^{\prime} .
$$

Proof. The key is to show that for every $a \in U_{1}$ its nearest-point projection $b=P_{U_{2}}(a)$ lies in the $R^{\prime}$-neighborhood of $U_{1}$.

Suppose $a_{1} \in U_{1}, b_{1} \in U_{2}$ are such that $d\left(a_{1}, b_{1}\right) \leq R$. By Lemma 1.102, there exists a point $c \in a b_{1}$ within distance $\lambda+2 \delta$ from $b$. Since $d\left(a_{1}, b_{1}\right) \leq R$, the $\delta$-slimness of the triangle $\Delta a a_{1} b_{1}$ implies existence of a point $c_{1} \in a a_{1}$ within distance $R+\delta$ from $c$. In view of the $\lambda$-quasiconvexity of $U_{1}, c_{1}$ belongs to the $\lambda$-neighborhood of $U_{1}$. Thus,

$$
b \in N_{2 \lambda+3 \delta+R}\left(U_{1}\right)=N_{R^{\prime}}\left(U_{1}\right) .
$$

Therefore, the distance from $b$ to $P_{U_{2}}(b)$ is at most $R^{\prime}$, verifying the inclusion

$$
P_{U_{2}}\left(U_{1}\right) \subset N_{R^{\prime}}\left(P_{U_{1}}\left(U_{2}\right)\right) .
$$

The reverse inclusion is proven by switching the roles of $U_{1}$ and $U_{2}$.
Continuing with the notation of the lemma:
Corollary 1.128. If $d\left(U_{1}, U_{2}\right) \leq R$, then

$$
\operatorname{Hd}\left(P_{U_{1}}\left(U_{2}\right), N_{R^{\prime}}\left(U_{2}\right) \cap U_{1}\right) \leq 2 R^{\prime} \text { and } \operatorname{Hd}\left(N_{R^{\prime}}\left(U_{1}\right) \cap U_{2}, N_{R^{\prime}}\left(U_{2}\right) \cap U_{1}\right) \leq R^{\prime}
$$

Proof. 1. According to the lemma, $P_{U_{1}}\left(U_{2}\right) \subset N_{R^{\prime}}\left(U_{2}\right) \cap U_{1}$. Conversely, given $x \in N_{R^{\prime}}\left(U_{2}\right) \cap U_{1}$, there exists $y \in U_{2}$ with $d(x, y) \leq R^{\prime}$. Hence, $d\left(y, P_{U_{1}}\left(U_{2}\right)(y)\right) \leq R$, implying

$$
d\left(x, P_{U_{1}}\left(U_{2}\right)(y)\right) \leq 2 R^{\prime}
$$

2. The second claim is clear and holds for arbitrary $R^{\prime} \geq 0$ and arbitrary subsets of arbitrary metric spaces.

Thus, we proved that if $d\left(U_{1}, U_{2}\right) \leq R$, then all four subsets

$$
P_{U_{1}}\left(U_{2}\right), P_{U_{2}}\left(U_{1}\right), N_{R^{\prime}}\left(U_{1}\right) \cap U_{2}, N_{R^{\prime}}\left(U_{2}\right) \cap U_{1}
$$

are within Hausdorff distance $2 R^{\prime}$ from each other.

### 1.20. Quasiconvex subgroups and actions

In this section we discuss quasiconvexity in the context of subgroups of hyperbolic groups and, more generally, group actions.

Definition 1.129. A subgroup $H$ of a hyperbolic group $G$ is said to be quasiconvex if it is a quasiconvex subset of a Cayley graph of $G$ for a finite generating set. More generally, a (metrically) proper isometric action of a discrete group $H$ on a geodesic hyperbolic metric space $X$ is quasiconvex if one (equivalently, every) $H$-orbit in $X$ is a quasiconvex subset in $X$.

Lemma 1.130. If the action of $H$ on $X$ is quasiconvex then $H$ is finitely generated, the orbit map $H \rightarrow H \cdot x \subset X$ is a qi embedding and $H$ is a hyperbolic group.

Proof. 1. Quasiconvexity of $H x \subset X$ implies that $H x$ is coarsely connected. Hence, by the Milnor-Schwarz Lemma, $H$ is finitely generated. We, thus, equip $H$ with a word metric corresponding to a finite generating set.
2. Metric properness of the action implies that the orbit map $o_{x}: H \rightarrow H x \subset X$ is uniformly proper. Since the image of this map is a quasiconvex subset of $X$, the orbit map is a qi embedding (see Lemma 1.91).
3. Since $X$ is assumed to be hyperbolic, in view of Lemma 1.55, the existence of a qi embedding $o_{x}$ implies hyperbolicity of $H$.

We now discuss the notion of coarse intersection in relation to quasiconvex subgroups and actions.

For general quasiconvex subsets $U, V$ of hyperbolic spaces $X$, coarse intersections $N_{R}(U) \cap V$ might not be Hausdorff-close to the actual intersections $U \cap V$ : For instance, $U \cap$ $V$ might be empty while for some $R>0$ the intersection $N_{R}(U) \cap V$ might be unbounded. As a specific example, consider $X=\mathbb{R}$ (which is 0-hyperbolic) and 1-quasiconvex subsets $U, V$ consisting of odd/even integers respectively. Then $N_{1}(U) \cap V=V$, while $U \cap V=\emptyset$. Nevertheless, in the group-theoretic setting we have

Lemma 1.131. Let $G$ be a hyperbolic group, $U, V$ be quasiconvex subgroups in $G$ with $W:=U \cap V$. Then for every $r>0$ there exists $R=R_{1.131}(G, r)$ such that

$$
W \subset W_{r}:=V \cap N_{r}(U) \subset N_{R}(W)
$$

Proof. The proof is quite standard, cf. [Gro93, pp. 164-165] or Lemma 2.6 in [GMRS98]. Suppose that $u \in U, v \in V$ satisfy $d_{G}(u, v) \leq r$, i.e. $u^{-1} v \in B_{G}(1, r)$. Since the ball $B_{G}(1, r)$ is finite, there exists a finite set of pairs $\left(u_{i}, v_{i}\right), i=1, \ldots, n$ such that for any pair $u \in U, v \in V$ within distance $r$ from each other, the product $u^{-1} v$ equals $u_{i}^{-1} v_{i}$ for some $i \in\{1, \ldots, n\}$. We have

$$
u^{-1} v=u_{i}^{-1} v_{i} \Rightarrow u u_{i}^{-1}=v v_{i}^{-1}=w \in W=U \cap V
$$

Hence, $u=w u_{i}, v=w v_{i}$ and, therefore, for

$$
R:=\max \left\{\left|v_{i}\right|: i=1, \ldots, n\right\}
$$

we have $d_{G}(v, W) \leq R$.

Corollary 1.132. In the setting of Lemma 1.131, the distance between the restrictions to $V$ of the projections $P_{X, W}, P_{X, U}$, is at most $C_{1.132}(G, \delta, \lambda)$, where $\delta$ is the hyperbolicity constant of $G$ and $\lambda$ is the maximum of the quasiconvexity constants of $U, V$ in $G$.

Proof. We take $r:=r_{1.108}(\lambda, \lambda, \delta)$. According to Lemma 1.108, the restrictions to $V$ of the projections

$$
P_{G, W_{r}}, P_{G, U}
$$

are within distance $\mu+3 \delta+r$. By Lemma 1.131, the subsets $W$, $W_{r} \subset X$ are $R=R_{1.131}(G, r)-$ Hausdorff-close. Therefore, by Corollary 1.105, the distance between the projections $P_{G, W_{r}}, P_{G, W}$ is $\leq D_{1.105}(\delta, \lambda, R)$. Thus, we can take

$$
C_{1.132}(G, \delta, \lambda):=D_{1.105}(\delta, \lambda, R)+\mu+3 \delta+r .
$$

As an immediate consequence we obtain the standard result on intersections of quasiconvex subgroups of hyperbolic groups (see e.g. [Sho91] or [BH99, Proposition 4.13]):

Corollary 1.133. If $G$ is a hyperbolic group and $U, V$ are quasiconvex subgroups of $G$, then $U \cap V$ is also a quasiconvex subgroup of $G, H$ and $V$.

Proof. This is a combination of Lemmata 1.131, 1.126 and 1.88(2).
Essentially the same proofs as above work in the more general setting, when we have a quasiconvex metrically proper action of a hyperbolic group $G$ on a $\delta$-hyperbolic geodesic metric space $X$, and $Y \subset X$ is a quasiconvex subset with locally finite $G$-orbit (see Definition 1.5).

Proposition 1.134. Let $H<G$ denote the stabilizer of $Y$ in $G, x \in Y$. Then:
a. There exists a function $R=R_{1.134}(x, r)$ such that

$$
H x \subset G x \cap N_{r}(Y) \subset N_{R}(H x)
$$

b. Hx is a quasiconvex $\mu$-subset of $X, \mu=\mu_{1.134}(x, \delta, \lambda)$, where $\lambda$ is the maximum of quasiconvexity constants (in $X$ ) of $G x$ and $Y$.
c. $H$ is a quasiconvex subgroup of $G$.
d. The restrictions of $P_{X, Y}$ and $P_{X, H x}$ to the orbit $G x \subset X$ are within distance $C=$ $C_{1.134}(x, \delta, \lambda)$.

Proof. a. Suppose that $d_{X}(g x, Y) \leq r$ for some $g \in G$; equivalently, $g^{-1} Y \cap B(x, r) \neq \emptyset$. By the definition of a local finiteness of the $G$-orbit $G Y$, there exist $h^{-1} \in H$ and $g_{i}^{-1} \in S$, where $S \subset G$ is a finite subset depending only on $x$ and $r$, such that $g^{-1}=g_{i}^{-1} h^{-1}$. We let $R=R(x, r)$ be the maximum of distances $d\left(x, g_{i}^{-1}(x)\right)$ taken over $g_{i}^{-1} \in S$. Then $d(h x, g x) \leq$ $R$. This proves (a).
b. We take $r:=2 \lambda+2 \delta$. By Lemma 1.126, the coarse intersection $G x \cap N_{r}(Y)$ is $\lambda_{1.126}(r, \delta)$-quasiconvex in $X$. On the other hand, by Part (a),

$$
\operatorname{Hd}\left(H x, G x \cap N_{r}(Y)\right) \leq R .
$$

Therefore, by Lemma 1.88(2), the subset $H x$ is $\mu$-quasiconvex in $X$ with

$$
\mu=2 R+2 \delta+\lambda_{1.126}(r, \delta)
$$

c. Since the actions of $G$ and $H$ on $X$ are quasiconvex, the orbit maps $o_{x}: G \rightarrow X$, $o_{x}: H \rightarrow X$ are qi embeddings (see Lemma 1.130). From this, we conclude that $H$ is qi embedded and, hence, is quasiconvex in $G$.
d. The proof of this part is identical to that of Corollary 1.132 and we omit it.

We assume now that $X$ is hyperbolic and that for each point $x \in X$ and each ideal boundary point $\xi \in \partial_{\infty} X$, there exists a geodesic ray $x \xi$ connecting $x$ to $\xi$ (e.g. $X$ is a proper geodesic metric space).

Definition 1.135. Suppose that $G$ acts isometrically and properly on $X$. A point $\xi \in$ $\partial_{\infty} X$ is called a limit point of this action (or, simply, a limit point of $G$ ) if there exists a sequence $g_{i} \in G$ such that for some (equivalently, every) $x \in X$, the sequence $\left(g_{i}(x)\right)$ converges to $\xi$. A limit point $\xi$ is called conical if the sequence $\left(g_{i}\right)$ can be chosen so that for some (equivalently, all) $x \in X, y \in X$, there exists a constant $R$ such that $d\left(g_{i} y, x \xi\right) \leq R$ for all $i$.

The proof of the following result (a Beardon-Maskit criterion for quasiconvexity) can be found for instance in Swenson's paper [Swe01] (cf. also [Bow95, Bow99, Tuk98]); we will only need the easier direction (every limit point of a quasiconvex action is conical):

Theorem 1.136. Suppose that $X$ is a proper geodesic hyperbolic metric space. Then a proper isometric action of a discrete group $G \curvearrowright X$ is quasiconvex if and only if every limit point of $G$ is conical.

### 1.21. Cobounded pairs of subsets

Recall that in Definition 1.25 we defined Lipschitz-cobounded pairs of subsets of general metric spaces. Below, we establish a characterization of cobounded pairs in hyperbolic spaces.

Proposition 1.137 (Characterizations of cobounded pairs). The following are equivalent for $\lambda$-quasiconvex subsets $Y, Z \subset X$ in a $\delta$-hyperbolic geodesic metric space $X$ :
(1) $Y, Z$ are $C_{1}$-Lipschitz cobounded.
(2) For every $R$ there exists $D=D(R)$ such that if

$$
a_{i} \in Y, b_{i} \in Z, i=1,2
$$

satisfy $d\left(a_{i}, b_{i}\right) \leq R, i=1,2$, then $d\left(a_{1}, a_{2}\right) \leq D, d\left(b_{1}, b_{2}\right) \leq D$.
(3) The diameters of nearest-point projections $P_{X, Y}(Z), P_{X, Z}(Y)$ are $\leq C_{2}$.

Moreover, once a constant $C_{i}$ (or a function $D(R)$ ) in one of the items is chosen, this, together with $\delta$ and $\lambda$, determines the constant/function in the other two items.

Proof. The implication $(1) \Rightarrow(2)$ is proven in Lemma 1.26 for arbitrary subsets of arbitrary metric spaces, with

$$
D=2 C_{1}(R+1)+C_{1}
$$

For the implication (2) $\Rightarrow(3)$, consider points $a_{i} \in Y, b_{i} \in Z$ such that $a_{i} \in P_{X, A}\left(b_{i}\right), i=$ 1,2 . By Lemma 1.120, if $d\left(a_{1}, a_{2}\right) \geq D_{1.120}(\delta, \lambda)$ then there exists $R=R_{1.120}(\delta, \lambda)$ such that

$$
a_{1} a_{2} \subset N_{R}\left(b_{1} b_{2}\right)
$$

In that case, there are points $b_{i}^{\prime} \in Z$ within distance $\leq R+\lambda$ from $a_{i}, i=1,2$. Then, by (2),

$$
d\left(a_{1}, a_{2}\right) \leq D(R+\lambda)
$$

Hence, we can take $C_{2}=\max \left\{D_{1.120}(\delta, \lambda), D(R+\lambda)\right\}$.
For the implication $(3) \Rightarrow(1)$, we can take the retractions

$$
r_{A}:=P_{X, A}, \quad r_{B}:=P_{X, B}
$$

In view of this proposition, for quasiconvex subsets of hyperbolic spaces we will adopt the following terminology:

Definition 1.138. A pair of subsets $Y, Z \subset X$ in a hyperbolic space $X$ is $C$-cobounded if the diameters of the projections $P_{X, Y}(Z), P_{X, Z}(Y)$ are $\leq C$.

Lemma 1.139. Given $\delta \geq 0$ and $\lambda \geq 0$ there are constants $R=R_{1.139}(\delta, \lambda)$ and $D=$ $D_{1.139}(\delta, \lambda)$ such that the following holds:

Suppose $X$ is a $\delta$-hyperbolic metric space and $Y, Z \subset X$ are two $\lambda$-quasiconvex and $R$-separated subsets. Then $Y, Z$ are $D$-cobounded. In fact, one can take $D=2 \lambda+7 \delta$ and $R=2 \lambda+5 \delta$.

Proof. We will show that the choice of $D=D_{1.120}(\delta, \lambda)=2 \lambda+7 \delta$ and

$$
R=\lambda+R_{1.120}(\delta, \lambda)=2 \lambda+5 \delta
$$

works. Let $R_{1}=R_{1.120}(\delta, \lambda)$, so that $R=\lambda+R_{1}$. Suppose the diameter of $P_{X, Z}(Y)$ is greater than or equal to $D$. Let $x, y \in Y$ be such that $d\left(P_{X, Z}(x), P_{X, Z}(y)\right) \geq D$. Then by Lemma $1.120 P_{X, Z}(x) \in N_{R_{1}}(x y)$. But $Y$ is $\lambda$-quasiconvex and $x, y \in Z$. It follows that $P_{X, Z}(x) \in N_{R}(Y)$. Thus if $Y, Z$ are $R$-separated then the diameter of $P_{X, Y}(Z)$ and $P_{X, Z}(Y)$ are both less than $D$.

A consequence of this lemma allows one to simplify the verification that two subsets are cobounded; namely, it suffices to check only that one projection is bounded:

Corollary 1.140. Suppose that $U, V \subset X$ are $\lambda$-quasiconvex subsets in a $\delta$-hyperbolic space.
a. If $\operatorname{diam}\left(P_{U}(V)\right) \leq D$, then $\operatorname{diam}\left(P_{V}(U)\right) \leq C=C_{1.140}(\lambda, \delta, D)$, where $D \leq C$. In particular, the pair $(U, V)$ is $C$-cobounded.
b. If the pair $U, V \subset X$ is not $D_{1.139}(\delta, \lambda)$-cobounded then

$$
\operatorname{Hd}\left(P_{U}(V), P_{V}(U)\right) \leq D_{1.140}(\delta, \lambda)=R_{1.140}(\delta, \lambda)=2 \lambda+3 \delta+R_{1.139}(\delta, \lambda)
$$

Proof. a. There are two cases to consider:

1. If $d(U, V) \geq R=R_{1.139}(\delta, \lambda)$, then the pair $(U, V)$ is $D_{1.139}(\delta, \lambda)$-cobounded by Lemma 1.139.
2. Suppose that $d(U, V) \leq R=R_{1.139}(\delta, \lambda)$. Then by Lemma 1.127,

$$
\operatorname{Hd}\left(P_{U}(V), P_{V}(U)\right) \leq R^{\prime}=2 \lambda+3 \delta+R
$$

Since $\operatorname{diam}\left(P_{U}(V)\right) \leq D$, it follows that

$$
\operatorname{diam}\left(P_{V}(U)\right) \leq D+R^{\prime}
$$

Taking $C:=\max \left(D+R^{\prime}, D_{1.139}(\delta, \lambda)\right)$, concludes the proof of a.
Remark 1.141. Note that $C=\max \left(D+4 \lambda+8 \delta, D_{1.120}(\delta, \lambda)\right)$.
b. By the argument in Part a1, since the pair $U, V \subset X$ is not $D_{1.139}(\delta, \lambda)$-cobounded, $d(U, V)<R=R_{1.139}(\delta, \lambda)$. Thus, as in Part a2,

$$
\operatorname{Hd}\left(P_{U}(V), P_{V}(U)\right) \leq R^{\prime}=2 \lambda+3 \delta+R=2 \lambda+3 \delta+R_{1.139}(\delta, \lambda)
$$

Remark 1.142. If $U_{1}, U_{2}$ are geodesics in $X, \lambda=\delta$ and, by Lemma 1.120, one can take $D_{1.139}(\delta, \delta)=8 \delta$ and $R_{1.140}(\delta, \lambda)=12 \delta$.

Another application of Lemma 1.139 is:
Corollary 1.143. Suppose that $\lambda$-quasiconvex subsets $U_{1}, U_{2} \subset X$ are not $D=$ $D_{1.139}(\delta, \lambda)$-cobounded. Then

$$
P_{U_{2}}\left(U_{1}\right) \subset N_{4 \lambda+8 \delta}\left(U_{1}\right) \cap U_{2}
$$

Proof. By Lemma 1.139 , since $U_{1}, U_{2}$ are not $D$-cobounded, then

$$
d\left(U_{1}, U_{2}\right) \leq R=R_{1.139}(\delta, \lambda)=2 \lambda+5 \delta
$$

According to Lemma 1.127,

$$
P_{U_{2}}\left(U_{1}\right) \subset N_{R^{\prime}}\left(U_{1}\right) \cap U_{2},
$$

where $R^{\prime}=2 \lambda+3 \delta+R=4 \lambda+8 \delta$.

Lemma 1.144. Given $\delta \geq 0, \lambda \geq 0$ and $C \geq 0$, there exists a constant $D=D_{1.144}(\delta, \lambda, C)$ such that the following holds:

Suppose $X$ is a $\delta$-hyperbolic metric space and $U, V \subset X$ are two nonempty $\lambda$-quasiconvex and C-cobounded subsets. Then there are points $x_{0} \in U_{0}=P_{U}(V) \subset U, y_{0} \in V_{0}=$ $P_{V}(U) \subset V$, such that $x_{0} y_{0} \subset N_{D}(x y)$, for all $x \in U$ and $y \in V$.

Proof. Since the pair $(U, V)$ is $C$-cobounded,

$$
\operatorname{diam}\left(V_{0}\right) \leq C, \quad \operatorname{diam}\left(U_{0}\right) \leq C
$$

Choose any pair of points $x_{0} \in U_{0}, y_{0} \in V_{0}$. Take $x \in U, y \in V$ and consider the points $\bar{x}=P_{V}(x) \in V_{0}, \bar{y}=P_{U}(y) \in U_{0}$. By Lemma 1.102, the points $\bar{x}, \bar{y}$ are within distance $\lambda+2 \delta$ from $x y$. Therefore,

$$
\max \left(d\left(x_{0}, x y\right), d\left(y_{0}, x y\right)\right) \leq \lambda+2 \delta+C
$$

and, hence, we can take $D=\lambda+4 \delta+C$.
Corollary 1.145. Given $\delta \geq 0$ and $\lambda \geq 0$, there are constants $R=R_{1.145}(\delta, \lambda)$ and $D=D_{1.145}(\delta, \lambda)$ such that the following holds:

Suppose $X$ is a $\delta$-hyperbolic metric space and $U, V \subset X$ are two $\lambda$-quasiconvex and $R$-separated subsets. Then there are points $x_{0} \in U, y_{0} \in V$ such that $x_{0} y_{0} \subset N_{D}(x y)$, for all $x \in U$ and $y \in V$.

Proof. By Lemma 1.139, there exists $R=R_{1.139}$ such that the pair $(U, V)$ is $C=$ $D_{1.139}$-cobounded whenever $U, V$ are $R$-separated. Now, the claim follows from Lemma 1.144.

## CHAPTER 2

## Graphs of groups and trees of metric spaces

### 2.1. Generalities

We presume that the reader is familiar with the Bass-Serre theory. However, we briefly recall some of the concepts that we shall need. For details we refer the reader to Section 5.3 of Serre's book [Ser03].

Definition 2.1 (Graph of groups). A graph of groups $(\mathcal{G}, \Gamma)$ consists of the following data:
(1) A connected graph $\Gamma$.
(2) An assignment to each vertex $v \in V(\Gamma)$ (and edge $e \in E(\Gamma)$ ) of a group $G_{v}$ (respectively $G_{e}$ ) together with injective homomorphisms $\phi_{e, o(e)}: G_{e} \rightarrow G_{o(e)}$ and $\phi_{e, t(e)}: G_{e} \rightarrow$ $G_{t(e)}$ for all $e \in E(\Gamma)$, such that the following conditions hold:
(i) $G_{e}=G_{\bar{e}}$,
(ii) $\phi_{e, o(e)}=\phi_{\bar{e}, t(\bar{e})}$ and $\phi_{e, t(e)}=\phi_{\bar{e}, o(\bar{e})}$.

We shall refer to the maps $\phi_{e, v}$ as the canonical maps of the graph of groups. We shall refer to the groups $G_{v}$ and $G_{e}, v \in V(\Gamma)$ and $e \in E(\Gamma)$ as vertex groups and edge groups respectively. For topological motivations of graph of groups and the following definition of the fundamental group of a graph of groups one is referred to [SW79] or [Hat02]. In the terminology of [BH99], a graph of groups is a covariant functor from the graph $\Gamma$ (regarded as a small category with set of objects $E \sqcup V$ and the set of morphisms consisting of the maps $o$ and $t$ ) to the category of groups, sending morphisms $o, t$ to group-monomorphisms. Functorially, in the case when $\Gamma$ is a tree, one can define the group $G$, the fundamental group of $(\mathcal{G}, \Gamma)$, or the pushout of the diagram $\mathcal{G}$, by a universal property. Namely, there exist monomorphisms $G_{e} \rightarrow G, G_{v} \rightarrow G$ such that the diagrams

commute, and, whenever we have a group $H$ and a compatible collection of homomorphisms $G_{e} \rightarrow H, G_{v} \rightarrow H$ forming commutative diagrams

there is a unique homomorphism $G \rightarrow H$ forming commutative diagrams

The general definition is more complicated:
Definition 2.2 (Fundamental group of a graph of groups). Suppose $(\mathcal{G}, \Gamma)$ is a graph of groups and let $S \subset \Gamma$ be a maximal (spanning) subtree. Then the fundamental group $G=\pi_{1}(\mathcal{G}, \Gamma, S)$ of $(\mathcal{G}, \Gamma)$ is defined in terms of generators and relators as follows:

The generators of $G$ are the elements of the disjoint union of the generating sets of the vertex groups $G_{v}, v \in V(\Gamma)$ and the set $E(\Gamma)$ of oriented edges of $\Gamma$.

The relators are of four types:
(1) Those coming from the vertex groups;
(2) $\bar{e}=e^{-1}$ for all edge $e$;
(3) $e=1$ whenever $|e|$ is a unoriented edge of $S$;
(4) $e \phi_{e, t(e)}(a) e^{-1}=\phi_{e, o(e)}(a)$ for all oriented edges $e$ and $a \in G_{e}$.

The group $G$ does not depend on the choice of $S$ and it will be denoted $G=\pi_{1}(\mathcal{G})$ in what follows. We will also frequently suppress the letter $\Gamma$ in the notation of a graph of groups.

Definition 2.3 (Bass-Serre tree of a graph of groups). Suppose $(\mathcal{G}, \Gamma)$ is a graph of groups and let $S$ be a maximal tree in $\Gamma$ as in the above definition. Let $G=\pi_{1}(\mathcal{G}, \Gamma, S)$ be the fundamental group of this graph of groups. The Bass-Serre tree, denoted $T$, is the tree with the vertex set

$$
\coprod_{v \in V(\Gamma)} G / G_{v}
$$

and the edge set

$$
\coprod_{e \in E(\Gamma)} G / G_{e}^{e}
$$

where $G_{e}^{e}=\phi_{e, t(e)}\left(G_{e}\right)<G_{t(e)}$. The origin/terminus maps are given by

$$
t\left(g G_{e}^{e}\right)=g G_{t(e)}, o\left(g G_{e}^{e}\right)=g G_{o(e)}
$$

Note that whenever $|e|$ is a unoriented edge of $S$, then we have $e=1$ in $G$. The group $G$ acts on $T$ via left multiplication.

Conversely, given an action without inversions ${ }^{1}$ of a group $G$ on a tree $T$, there exists a graph of groups $\mathcal{G}$ with $\pi_{1}(\mathcal{G}) \cong G$ such that $T$ is equivariantly isomorphic to the BassSerre tree of $\mathcal{G}$, see [Ser03].

Since our main motivation comes from geometric group theory and, hence, finitely generated groups, we observe that for $G=\pi_{1}(\mathcal{G}, \Gamma, S)$ to be finitely generated, it suffices (not not necessary!) to assume that each vertex group $G_{v}$ is finitely generated and the graph $\Gamma$ is finite. On the other hand, the edge groups $G_{e}$ need not be finitely generated. Natural examples of the latter situation are given by amalgams

$$
G=G_{v} \star_{G_{e}} G_{w},
$$

[^3]where $G_{e}$ is an infinite rank free subgroup in two finitely-presented groups $G_{v}, G_{w}$ : Such groups $G$ are finitely generated but not finitely presentable. In the context of combination theorems for hyperbolic groups, one assumes that the graph $\Gamma$ is finite, each vertex/edge group is hyperbolic and the monomorphisms $\phi$ are qi embeddings, i.e. have quasiconvex images.

Returning to the general setting with finitely generated vertex groups and finite graph $\Gamma$, we note that while it is meaningless to assume that the canonical maps $\phi$ are uniformly proper (as edge-groups do not have canonical qi classes of metrics), nevertheless, if we equip $G_{e}$ with the pull-back a word metric from $G_{o(e)}$, while $G_{t(e)}$ has a word metric coming from a finite generating set, then the monomorphism $G_{e} \rightarrow G_{t(e)}$ is uniformly proper. Since the graph $\Gamma$ is finite, we conclude that each edge group has a left-invariant proper metric, such that the homomorphisms $\phi_{e, o(e)}$ and $\phi_{e, t(e)}$ are $(\eta, L)$-proper for some uniform function $\eta$ and a constant $L$.

A morphism of graphs of groups, $\Psi: \mathcal{G} \rightarrow \mathcal{G}^{\prime}$, consists of a morphism of the underlying graphs $\psi: \Gamma \rightarrow \Gamma^{\prime}$ together with a collection of group homomorphisms

$$
\Psi_{v}: G_{v} \rightarrow G_{\psi(v)}, v \in V(\Gamma), \quad \Psi_{e}: G_{e} \rightarrow G_{\psi(e)}, e \in E(\Gamma)
$$

such that the following diagrams are commutative for $v=o(e)$ and $w=t(e)$ and their respective images $v^{\prime}=\psi(v), w^{\prime}=\psi(w), e^{\prime}=\psi(e)$ :

Given a graph of groups ( $\mathcal{G}^{\prime}, \Gamma^{\prime}$ ) and a graph-morphism $\psi: \Gamma \rightarrow \Gamma^{\prime}$ from a connected graph $\Gamma$, there is a canonical pull-back graph of groups $(\mathcal{G}, \Gamma)$ and a morphism of graphs of groups $\Psi: \mathcal{G} \rightarrow \mathcal{G}^{\prime}$, such that the underlying morphism of graphs $\Gamma \rightarrow \Gamma^{\prime}$ equals $\psi$. In the special case when $\Gamma$ is a connected subgraph of $\Gamma^{\prime}$, the graph of groups $(\mathcal{G}, \Gamma)$ is called the restriction of $\mathcal{G}^{\prime}$ to $\Gamma$ (see [Bas93, 2.15]). In this case, the Bass-Serre tree $T$ of $(\mathcal{G}, \Gamma)$ admits a $G=\pi_{1}(\mathcal{G})$-equivariant embedding in the Bass-Serre tree $T^{\prime}$ of ( $\mathcal{G}^{\prime}, \Gamma^{\prime}$ ) and $G$ equals the stabilizer of $T \subset T^{\prime}$ in $G^{\prime}$. We refer the reader to [Bas93] for further discussion of morphisms of graphs of groups.

In the book, on several occasions we will use the following definition from the theory of group actions on trees:

Definition 2.4. An action of a group $G$ on a tree $T$ is said to be $k$-acylindrical if whenever a nontrivial ${ }^{2}$ element $g \in G$ fixes element-wise an interval $J \subset T$, then $J$ has length $\leq k$.

This terminology originates in Sela's paper [Sel97]. The definition of acylindrical actions on trees was later coarsified and generalized by Bowditch in [Bow08]; we will not use his generalization.

[^4]
### 2.2. Trees of spaces

Each graph of groups yields a "tree of metric spaces" over its Bass-Serre tree; this was first formalized and used by Bestvina and Feighn in [BF92]. Below is our version of their definition.

We start with the simpler concept of a tree of topological spaces. One can regard a (simplicial) tree $T$ (or a general graph) as a small category with object sets equal to $V(T) \sqcup E(T)$ and morphisms given by origin/terminus arrows. Then a tree of topological spaces over a tree $T$ is a functor $\mathfrak{X}$ from $T$ to the category of topological spaces. More explicitly:

Definition 2.5. A tree of topological spaces over a tree $T$ is a collection $\mathfrak{X}$ of nonempty topological spaces (vertex and edge-spaces) $X_{v}, v \in V(T), X_{e}, e \in E(T)$, together a collection of continuous incidence maps $f_{e v}: X_{e} \rightarrow X_{v}$ defined for each oriented edge $e=[v, w]$. The total space $X$ of $\mathfrak{X}$ is the mapping cylinder of the collection of the maps $f_{e v}$, i.e. the quotient of the disjoint union

$$
\coprod_{v \in V(T)} X_{v} \sqcup \coprod_{e \in E(T)} X_{e} \times[0,1]
$$

by the equivalence relation

$$
(x, 0) \sim f_{e v}(x),(x, 1) \sim f_{e w}(x), e=[v, w] \in E(T)
$$

We will use trees of topological spaces in Section 8.9. For most of the book, we will work with trees of metric spaces defined below.

Again, regarding a tree $T$ as a small category, to some degree, a tree of metric spaces $\mathfrak{X}$ over a tree $T$ is a functor from $T$ to the coarse category $\mathcal{C}$, see Remark 1.16. The actual definition is somewhat more restrictive:

Definition 2.6 (Abstract tree of spaces). An abstract tree of (metric) spaces $\mathfrak{X}$ over a simplicial tree $T$, is a collection of nonempty metric spaces (vertex and edge-spaces) $X_{v}, v \in V(T), X_{e}, e \in E(T)$, together a collection of $\psi$-uniformly proper coarse $L$-Lipschitz incidence maps $f_{e v}: X_{e} \rightarrow X_{v}$ defined for each oriented edge $e=[v, w]$. The constant $L$ and the function $\psi$ are the parameters of the abstract tree of spaces $\mathfrak{X}$. The tree $T$ is the base of $\mathfrak{X}$.

Throughout the book, we will be assuming that all vertex-spaces $X_{v}$ are path-metric spaces.

In view of the approximation lemmata (Lemma 1.35 and Lemma 1.36), one can replace general path-metric spaces $X_{v}$ and incidence maps $f_{e v}$ by (connected) metric graphs (equipped with graph-metrics) and simplicial incidence maps. Below we define the total space $X$ of a tree of spaces and a projection $\pi: X \rightarrow T$. Thus, we will frequently refer to trees of spaces as $\mathfrak{X}=(\pi: X \rightarrow T)$, since the map $\pi$ records the most important information about $\mathfrak{X}$.

In important class of trees of spaces consists of metric bundles. We refer to [MS09] for the general definition; for the purpose of this book the following will suffice:

Definition 2.7. An abstract tree of spaces $\mathfrak{X}=(\pi: X \rightarrow T)$ is a metric bundle if the incidence maps $f_{e v}$ are uniform quasiisometries, i.e. there exists $\epsilon \geq 0$ such that for each edge $e=[v, w] \in E(T)$, the image $f_{e v}\left(X_{e}\right)$ (and, hence, $f_{e w}\left(X_{w}\right)$, by reversing the orientation on $e$ ) is $\epsilon$-dense in $X_{v}$.

While the main motivation for trees of spaces comes from graphs of groups, the main group-theoretic examples of metric bundles over trees are short exact sequences

$$
1 \rightarrow K \rightarrow G \rightarrow H \rightarrow 1
$$

where $K$ is a finitely generated group and $H$ is a free group of finite rank.
Definition 2.8. The total space, or the push-out, of a tree of spaces $\mathfrak{X}$ is a metric space $X$ admitting a collection of $L^{\prime}$-coarse Lipschitz maps $X_{e} \rightarrow X, e \in E(T), X_{v} \rightarrow X, v \in$ $V(T)$, and satisfying the following universal property: For every metric space $Y$ and a compatible collection of $L_{1}$-coarse Lipchitz maps $X_{e} \rightarrow Y, X_{v} \rightarrow Y$, there exists a unique, up to a uniformly bounded error, $L_{2}$-coarse Lipschitz map $X \rightarrow Y$ forming diagrams which commute up to a uniform error $C$ :

Here $L_{2}$ and $C$ depend on $L_{1}$.
This definition implies uniqueness (up to a quasiisometry) of the total space $X$. We will prove the existence of $X$ below (Theorem 2.14).

Definition 2.9. An abstract tree of spaces is said to be retractible (or retractive), if there exists a collection of (uniformly) $L$-coarse Lipschitz maps (retractions) $f_{v e}: X_{v} \rightarrow$ $X_{e}$ defined for oriented edges $e=[v, w]$, which are uniformly coarse left-inverses to the incidence maps $f_{e v}$, i.e.

$$
\operatorname{dist}\left(f_{v e} \circ f_{e v}, \operatorname{id}_{X_{e}}\right) \leq \epsilon,
$$

for some uniform constants $L \geq 1, \epsilon \in[0, \infty)$.
Under the retractibility assumption, the incidence maps are not only uniformly proper but are also uniformly quasiisometric embeddings. While the definition is general, in this book, vertex and edge-spaces mostly will be uniformly hyperbolic, images of edge-spaces in vertex spaces will be uniformly quasiconvex and the retractions $f_{v e}$ will be given by nearest-point projections $P_{X_{v}, X_{e}}: X_{v} \rightarrow X_{e v}$.

Morphisms. Let $\mathfrak{X}, \mathfrak{X}^{\prime}$ be abstract trees of spaces over trees $T, T^{\prime}$ respectively with the respective vertex/edge spaces $X_{v}, X_{v^{\prime}}^{\prime}, X_{e}, X_{e^{\prime}}^{\prime}$. A morphism of abstract trees of spaces $\mathfrak{X} \rightarrow \mathfrak{X}^{\prime}$ is a graph-morphism $T \rightarrow T^{\prime}, v \mapsto v^{\prime}, e \mapsto e^{\prime}$, together with a collection of uniformly coarse Lipschitz maps, between respective vertex and edge-spaces

$$
h_{v}: X_{v} \rightarrow X_{v^{\prime}}^{\prime}, \quad h_{e}: X_{e} \rightarrow X_{e^{\prime}}^{\prime}
$$

such that the diagrams (where the horizontal arrows are the incidence maps)

commute up to uniformly bounded errors. An isomorphism of abstract trees of spaces is an invertible morphism, equivalently, it is an isomorphism of trees $T \rightarrow T^{\prime}$ and a collection of uniform quasiisometries $X_{v} \rightarrow X_{v^{\prime}}^{\prime}, X_{e} \rightarrow X_{e^{\prime}}^{\prime}$.

Remark 2.10. In this book we will be only considering monic morphisms of trees of spaces, i.e. ones for which the graph-morphism $T \rightarrow T^{\prime}$ is injective and the maps $X_{v} \rightarrow X_{v^{\prime}}, X_{e} \rightarrow X_{e^{\prime}}^{\prime}$ are $\zeta$-proper for some uniform function $\zeta$.

Example 2.11. The most common examples of morphisms of trees of spaces used in this book are subtrees of spaces. Namely, let $S \subset T$ is a subtree, $\mathfrak{X}$ is a trees of spaces over $T$. Then the pull-back of $\mathfrak{X}$ over $S$ is a tree of spaces $\mathfrak{Y}$ such that $Y_{v}=X_{v}, Y_{e}=X_{e}$, $v \in V(S), e \in E(S)$. The collection of identity maps $Y_{v} \rightarrow X_{v}, Y_{e} \rightarrow X_{e}$ defines a morphism of trees of spaces $\mathfrak{Y}) \rightarrow \mathfrak{X}$. We will use the notation $X_{S}$ for the total space of the tree of spaces $\mathfrak{Y}$. In the case when $S$ is an interval (resp. tripod) in $T$, we will refer to $X_{S}$ as an interval-space (resp. tripod-space).

While the above definition is the main definition used in this book, we now connect the notion of an abstract trees of spaces to the notion of a tree of spaces as defined by Mitra in [Mit98]. According to Mitra's definition, a tree of metric spaces is a path-metric space equipped with a certain auxiliary data, such as a map to a simplicial tree and a collection of maps to $X$ from certain spaces. Below, we use the $\ell_{1}$-metric on $X_{e} \times[v, w]$. Recall that for edges $e$ of $T, \dot{e}$ denotes the edge minus its end-points; below we will use the notation $m(e)$ for the midpoint of $e$.

Definition 2.12 (Tree of spaces). A tree of metric spaces, denoted $\mathfrak{X}$, is a path-metric space ( $X, d$ ) equipped with a 1-Lipschitz surjective map $\pi: X \rightarrow T$ onto a simplicial tree $T$, satisfying the following:
(1) For each $v \in V(T)$, the corresponding vertex-space $X_{v}:=\pi^{-1}(v) \subset X$ is rectifiably connected.
(2) For every edge $e \in E(T)$, the edge-space $X_{e}:=\pi^{-1}(m(e))$ is rectifiably connected. Every oriented edge $e=[v, w]$ comes equipped with an $L$-Lipschitz ${ }^{3}$ $\eta$-proper map

$$
f_{e}: X_{e} \times[v, w] \rightarrow X
$$

such that $f_{e v}\left(X_{e} \times\{v\}\right) \subset X_{v}$.
By abusing the notation, we will denote a tree of spaces by $\pi: X \rightarrow T$. We will use the notation $f_{e v}$ for the composition

$$
X_{e} \rightarrow X_{e} \times\{v\} \xrightarrow{f_{e}} X_{v}
$$

and $X_{e v}:=f_{e v}\left(X_{e}\right)$.
Remark 2.13. Mitra also assumes that inclusion maps $X_{v} \rightarrow X$ to be $\zeta$-proper for some function $\zeta$. We will see below that this is a consequence of uniform properness of the maps $X_{e} \rightarrow X_{v}$.

Observe that each tree of spaces $\mathfrak{X}$ yields naturally an abstract tree of spaces $\mathfrak{X}^{a b}$, the abstraction of $\mathfrak{X}$, with the incidence maps $f_{e v}$. The next theorem is a converse to this abstraction procedure.

Theorem 2.14 (An existence theorem for trees of spaces). For each abstract tree of spaces $\mathfrak{X}$ over a tree $T$, there exists a (unique up to an isomorphism) tree of spaces ( $\pi$ : $X \rightarrow T$ ), called a concretization of $\mathfrak{Y}$, such that $\mathfrak{X}$ is isomorphic to the abstraction $\mathfrak{X}^{a b}$ of $(\pi: X \rightarrow T)$. The total space $X$ of $\mathfrak{X}$ satisfies the universal property in the Definition 2.8.

[^5]Proof. Our proof mimics the definition of the underlying topological space (equipped with the weak topology) of a cell complex, where the latter is defined via an inductively defined collection of attaching maps. We let $X$ denote the topological space obtained by attaching the products $X_{e} \times[0,1]$ to the disjoint union

$$
\mathcal{X}=\coprod_{v \in V(T)} X_{v}
$$

via the attaching maps $f_{e v}: X_{e} \times\{v\} \rightarrow X_{v}, f_{e w}: X_{e} \times\{w\} \rightarrow X_{w}, e=[v, w] \in E(T)$. In other words, $X$ is the mapping cylinder

$$
\operatorname{Cyl}\left(f: \mathcal{X}_{E} \rightarrow \mathcal{X}_{V}\right)
$$

of the map

$$
f: \mathcal{X}_{E}:=\coprod_{e \in E(T)} X_{e} \rightarrow \mathcal{X}_{V}:=\coprod_{v \in V(T)} X_{v},
$$

given by the collection of incidence maps $f_{e v}$. For each edge $e$ of $T$ we will identify $X_{e} \times \dot{e}$ with its image in $X$.

We define admissible paths in $X$ (see Section 1.4) to be the continuous maps $c$ : $[a, b] \rightarrow X$ which are concatenations of vertical paths, which are rectifiable (with respect to the metrics on vertex-spaces) paths contained in the vertex-spaces of $X$ and horizontal paths, which are rectifiable paths contained in the intervals of the form $x \times[0,1]$, $x \in X_{e}, e \in E(T)$. For every admissible path $c$, we let length(c) be the sum of measures of lengths of its vertical and horizontal components. We leave it to the reader to verify that this defines a length-structure on $X$ and, hence, a path-metric $d$. We retopologize $X$ using this path-metric. By the construction, each inclusion map $X_{e} \times \dot{e} \rightarrow X$ is an isometry to its image, each vertex space is rectifiably-connected in $X$, each inclusion map $X_{v} \rightarrow X$ is 1-Lipschitz and the projection map

$$
\pi: X \rightarrow T
$$

is 1-Lipschitz as well. The verification that the space $X$ satisfies the universal property is rather straightforward. Given a collection of compatible coarse $L$-Lipschitz maps $h_{v}$ : $X_{v} \rightarrow Y, h_{e}: X_{e} \rightarrow Y$ to a metric space $Y$, we define a map $h: X \rightarrow Y$ by sending each open interval $\{x\} \times(0,1) \subset X_{e} \times(0,1)$ to the point $h_{e}(x)$. The uniqueness of $h$ (up to a bounded error) follows from the fact that the union

$$
\coprod_{v \in V(T)} X_{v} \sqcup \coprod_{e \in E(T)} X_{e}
$$

forms a $1 / 2$-net in $X$. We will leave it to the reader to check that $\mathfrak{X}$ is isomorphic to the abstraction of $(\pi: X \rightarrow T)$.

Remark 2.15. 1. A definition similar to our abstract tree of spaces and a construction analogous to the one in the proof of Theorem 2.14 appear in the work of Cashen and Martin [CM17, 2.4]. However, they work in the category of proper metric spaces and the metric spaces they produce do not satisfy all the properties in Definition 2.12 and, hence, we cannot directly use their work.
2. Throughout the book, we will work with geometric realizations of trees of spaces constructed in the proof of Theorem 2.14. In particular, the inclusion maps

$$
X_{v} \rightarrow X
$$

are 1-Lipschitz. For every edge $e=[u, v] \in E(T)$ we will be frequently using the pathmetric spaces

$$
X_{u v}=X_{\llbracket u, v \rrbracket}=\pi^{-1}(\llbracket u, v \rrbracket) .
$$

The inclusion maps $X_{u} \rightarrow X_{u v} \leftarrow X_{v}$ are also 1-Lipschitz.
3. One drawback of our construction is that even if vertex and edge-spaces are complete and geodesic, the tree of spaces we construct in the proof of Theorem 2.14 is a only a path-metric space and, a priori, is not a geodesic metric space and need not be complete. There are two ways to rectify this issue which we describe below.
a. In the book, when we say "a geodesic" we really mean a path which is $\epsilon$-short for a suitably chosen sufficiently small $\epsilon>0$. Similarly, when dealing with nearest-point projections, we frequently project to non-closed subsets. Then a nearest-point projection of $x \in X$ to $Y \subset X$ is a point $\bar{x} \in Y$ such that for a suitable chosen, sufficiently small $\epsilon>0$,

$$
d(x, \bar{x}) \leq d(x, Y)+\epsilon
$$

b. For a reader uncomfortable with such a fudge, we describe an alternative approach to rectifying the issue with geodesics and nearest-point projections.

First of all, as we noted earlier (Lemmata 1.35, 1.36) without loss of generality, we may assume that all vertex spaces and edge-spaces $X_{v}, X_{e}$ are connected graphs equipped with standard graph-metrics. We will replace each $X_{e}$ with its vertex-space. Then the space $X$ defined in the proof of Theorem 2.14 is a connected graph and the path-metric on this graph defined in the proof is the standard graph-metric. The drawback of this approach is the need to keep track of combinatorial issues which, are, ultimately, irrelevant.

From now on, we will work with abstract trees of spaces $\mathfrak{X}$ and their concretizations $\pi: X \rightarrow T$. The metric space $X$ is the total space of $\mathfrak{X}$. There is nothing particularly canonical about our choice of $X$ in this construction, it is just something we find convenient to work with. The reader could alternatively work for instance with, say, the $\ell_{1}$-metric coming from the products $X_{e} \times[v, w]$ in the mapping cylinder $X$. In fact, most of our arguments deal with vertex-spaces and pull-backs $X_{v w}$ : We will be using the fact that the natural inclusion maps $X_{v} \rightarrow X_{v w} \leftarrow X_{w}$ are 1-Lipschitz and either uniformly proper or, for trees of hyperbolic spaces, uniform qi embeddings.

Example 2.16. One motivation for our construction of $X$ comes from Cayley graphs of fundamental groups $G$ of graphs of groups. We assume that $(\mathcal{G}, Y)$ is a finite graph of finitely generated groups, $S \subset Y$ is a spanning tree, and $G=\pi_{1}(\mathcal{G}, Y, S)$ is the fundamental group. We will identify $S$ with a subtree in the Bass-Serre tree $T$ of $(\mathcal{G}, Y)$. Then form a graph $\Gamma$ using the generators of $G$ as described in Definition 2.2, except:
(a) We fix an orientation of the edges of $Y$ and use only one generator per each edge (not two).
(b) We use the given generating sets of the vertex-groups $G_{v}$ instead of the entire $G_{v}$.

Thus, in the graph $\Gamma$ there are vertical edges (corresponding to translates $\Gamma_{v}, v \in V(T)$, of Cayley graphs of vertex groups) and horizontal edges (corresponding to the generators coming from the edges of $Y$ ). The vertex-spaces $X_{v}$ are, then the graphs $\Gamma_{v}$. The edgespaces are the translates of the edge-groups, $g G_{e}, g \in G, e \in E(Y)$. The incidence maps $f_{e v}, f_{e w}$ for the oriented edges $e=[v, w]$ in $S$ come from the monomorphisms $\phi_{e, o(e)}$ and
 maps are obtained by composing with the action of $G$ by left multiplication. Thus, we obtain a tree of spaces $\mathfrak{X}$ over $T$ with vertex spaces isometric to Cayley graphs of the vertex-groups $G_{v}, v \in V(Y)$, and edge-spaces isometric to edge-groups $G_{e}, e \in E(Y)$, with
metrics obtained via pull-backs of word-metrics on the incident vertex-groups $G_{v}, v=t(e)$. Note that in the Cayley graph of $G$ there are no edges corresponding to generators of the edge-groups. This is consistent to our use of only horizontal paths over the edges of $T$ in the construction of the total space $X$ in the proof of Theorem 2.14. We leave it to the reader to check that the Cayley graph $\Gamma$ as above is $G$-equivariantly isometric to the total space $X$ of the tree of spaces $\mathfrak{X}$ defined in the proof of Theorem 2.14.

Proposition 2.17. There exists a continuous function $\eta_{2.17}$ depending on the parameters of an abstract tree of spaces $\mathfrak{X}$, such that for every subtree $S \subset T$, the inclusion map

$$
X_{S} \rightarrow X
$$

is an $\eta_{2.17}$-uniformly proper embedding.
Proof. The key case to understand is when $T$ has a single edge $e=[u, v]$ and $S=\{u\}$. We let $Y$ denote the total space of the corresponding tree of spaces. It suffices to estimate (from below, in terms of $d_{X_{u}}\left(x, x^{\prime}\right)$ ) lengths of paths $c$ in $Y$ connecting $x=x_{1}, x^{\prime}=x_{n} \in X_{u}$, such that $c$ is a concatenation of the form

$$
c\left(x_{1}, y_{1}\right) \star c\left(y_{1}, z_{1}\right) \star c\left(z_{1}, z_{2}\right) \star c\left(z_{2}, y_{2}\right) \star c\left(y_{2}, x_{2}\right) \star c\left(x_{2}, x_{3}\right) \star \ldots \star c\left(y_{n}, z_{n}\right)
$$

where $x_{i}=f_{e u}\left(y_{i}\right), z_{i}=f_{e v}\left(y_{i}\right)$ and paths $c\left(x_{i}, y_{i}\right), c\left(y_{i}, z_{i}\right)$ are horizontal, while the paths $c\left(x_{j}, x_{j+1}\right), c\left(z_{k}, z_{k+1}\right)$ are vertical geodesics in the vertex-spaces $X_{u}, X_{v}$. The lengths of this path is

$$
\text { length }(c)=\sum_{i=\text { even }} d_{X_{u}}\left(x_{i}, x_{i+1}\right)+n+\sum_{j=\text { odd }} d_{X_{v}}\left(z_{j}, z_{j+1}\right)
$$

Assume that length $(c) \leq D$. Then $n \leq D$ and $d_{X_{v}}\left(z_{j}, z_{j+1}\right) \leq D$ for each odd index $j$. We have (for $j$ odd):

$$
L^{-1} d_{X_{u}}\left(x_{j}, x_{j+1}\right) \leq d_{X_{e}}\left(y_{j}, y_{j+1}\right) \leq \psi\left(d_{X_{v}}\left(z_{j}, z_{j+1}\right)\right)
$$

and, hence,

$$
d_{X_{u}}\left(x_{j}, x_{j+1}\right) \leq L \psi\left(d_{X_{u}}\left(z_{j}, z_{j+1}\right)\right) \leq L \psi(D) .
$$

Thus, the concatenation $c_{u}$ of vertical geodesics $\left[x_{i} x_{i+1}\right]_{X_{u}}$ connecting $x$ to $x^{\prime}$ has total length length $\left(c_{u}\right)$ satisfying

$$
\begin{array}{r}
d_{X_{u}}\left(x, x^{\prime}\right) \leq \text { length }\left(c_{u}\right)=\sum_{j=\text { odd }} d_{X_{u}}\left(x_{j}, x_{j+1}\right)+\sum_{i=\text { even }} d_{X_{u}}\left(x_{i}, x_{i+1}\right) \leq \\
L \sum_{j=\text { odd }} \psi(D)+\sum_{i=\text { even }} d_{X_{u}}\left(x_{i}, x_{i+1}\right) \leq L D \psi(D)+D .
\end{array}
$$

It follows that $d_{X_{u}}\left(x, x^{\prime}\right) \leq L D \psi(D)+D$ and, hence, the inclusion map $X_{u} \rightarrow X_{u v}$ is $\eta$-proper, for $\eta(D):=D(L \psi(D)+1)$.

Remark 2.18. Assuming that the map $f_{e v}: X_{e} \rightarrow X_{v}$ is an $L$-qi embedding (which will be eventually our assumption for trees of hyperbolic spaces), we obtain a better estimate:

$$
\begin{gathered}
d_{X_{u}}\left(x, x^{\prime}\right) \leq \operatorname{length}\left(c_{u}\right)=\sum_{j=\text { odd }} d_{X_{u}}\left(x_{j}, x_{j+1}\right)+\sum_{i=\text { even }} d_{X_{u}}\left(x_{i}, x_{i+1}\right) \leq \\
\sum_{i=\text { even }} d_{X_{u}}\left(x_{i}, x_{i+1}\right)+L^{2} \sum_{j=\text { odd }} d_{X_{v}}\left(z_{j}, z_{j+1}\right)+L^{3} n \leq L^{3} \text { length }(c) .
\end{gathered}
$$

Thus, we conclude that each inclusion map $X_{u} \rightarrow X_{u v}$ in this case is an ( $L^{3}, 0$ )-qi embedding.

We now deal with the general case. Consider an admissible path $\beta:[0,1] \rightarrow X$ connecting $x, y \in X_{S}$. The projection $\pi \circ \beta$ is a path $p$ in $T$ connecting $\pi(x)$ to $\pi(y)$ whose length is $\leq$ length $(\beta)$. Without loss of generality, we may assume that $\pi(x), \pi(y)$ are vertices in $S$ and $p$ is a simplicial path in $T$. We now construct inductively a sequence of paths

$$
\beta_{0}=\beta, \beta_{1}, \ldots, \beta_{n}
$$

in $X$ with simplicial projections to $T$, all connecting $x$ to $y$, such that:
(1) $\beta_{n}$ is a path in $X_{S}$.
(2) The length of $\pi \circ \beta_{i+1}$ is at most length $\left(\pi \circ \beta_{i}\right)-2$.
(3)

$$
\text { length }\left(\beta_{i+1}\right) \leq \eta\left(\text { length }\left(\beta_{i}\right)\right)
$$

where $\eta(D):=D(L \psi(D)+1)$ as above.
Assume that $\beta_{i}$ is defined. If this path is contained in $X_{S}$, then $n=i$ we are done. Otherwise, there exists an edge $e=[v, w]$ in the tree $\pi \beta_{i}([0,1])$ such that $\beta$ contains a subpath $\beta^{\prime}$ connecting points $x^{\prime}, y^{\prime} \in X_{v}$ and contained in the subspace $X_{v w}$. We then replace $\beta^{\prime}$ with a geodesic in $X_{v}$ connecting the end-points $x^{\prime}, y^{\prime}$ of $\beta^{\prime}$. By the above estimate in $X_{\nu w}$,

$$
d_{X_{v}}\left(x^{\prime}, y^{\prime}\right) \leq \eta\left(\text { length }\left(\beta^{\prime}\right)\right)
$$

and, hence, the new path $\beta_{i+1}$ satisfies the required conditions.
Clearly, $n \leq$ length $(\beta)$, hence,

$$
\text { length }\left(\beta_{n}\right) \leq \eta^{(n)}(\text { length }(\beta))
$$

where $\eta^{(n)}$ is the $n$-fold iteration of the function $\eta$. Therefore, for $\eta_{2.17}=\eta^{(n)}$,

$$
n=\left\lceil d_{X}(x, y)\right\rceil
$$

we obtain

$$
d_{X_{S}}(x, y) \leq \eta_{2.17}\left(d_{X}(x, y)\right) .
$$

Applying the arguments of the proof of the proposition with the linear estimate in Remark 2.18 we obtain:

Corollary 2.19. If each incidence map $f_{e v}$ is an L-qi embedding, then each $X_{S}$ is at most exponentially distorted in $X$, i.e. is $\eta$-uniformly properly embedded in $X$ with $\eta(t)=\exp (a t)$ for some $a \geq 1$ depending only on $L$.

We omit the proof of this corollary since it is straightforward and the result is not used elsewhere.

Definition 2.20. Let $\mathfrak{X}=(\pi: X \rightarrow T)$ be a tree of spaces.
(1) By a $K$-qi section (or a $K$-qi lift of $S$ ) over a subtree $S \subset T$ we mean a map $\sigma: S \rightarrow X$ such that for each vertex $v \in S, \sigma(v) \in X_{v}$, for any pair of adjacent vertices $u, v \in S$, we have $d_{X_{u v}}(\sigma(u), \sigma(v)) \leq K$ and the restriction of $\sigma$ to the interval $u v$ is a parameterization of a geodesic $\sigma(u) \sigma(v)$ in $X_{u v}$.
(2) $K$-qi lifts of geodesic segments of $T$ will be referred to as $K$-qi leaves in $X$ and denoted by $\gamma$ or $\gamma_{x}$ or $\gamma_{x y}$, provided they start at $x$ and end at $y$. We will refer to such $\gamma$ 's as horizontal paths in $X$.
(3) A vertical path in $X$ is a path contained in one of the vertex-spaces.
(4) If $Y$ is a subset of $X$ then the fiberwise neighborhood of $Y$ in $X$ (denoted $N_{r}^{f i b}(Y)$ ) is the union

$$
\bigcup_{v \in V(T)} N_{r}\left(Y \cap X_{v}\right)
$$

where the latter neighborhood is taken with respect to the (intrinsic) metric of $X_{v}$.

Let $\mathfrak{X}$ be an abstract tree of spaces. A subtree of spaces in $\mathfrak{X}=(\pi: X \rightarrow T)$ is a tree of spaces $\mathfrak{X}^{\prime}=\left(\pi^{\prime}: X^{\prime} \rightarrow T^{\prime}\right)$ whose base tree is a subtree $T^{\prime} \subset T$, and vertex/edge spaces $X_{v}^{\prime}, X_{e}^{\prime}$ are rectifiably connected uniformly properly embedded subsets of $X_{v}, X_{e}$ respectively, so that the incidence maps of $\mathfrak{X}^{\prime}$ are uniformly close to restrictions of incidence maps of $\mathfrak{X}$.

### 2.3. Coarse retractions

In this section we prove a general existence theorem of coarse Lipschitz left-inverses (retractions) for morphisms of trees of spaces.

Let $T^{\prime}$ be a subtree of $T$ and let $\mathfrak{X}=(\pi: X \rightarrow T), \mathfrak{X}^{\prime}=\left(\pi^{\prime}: X^{\prime} \rightarrow T^{\prime}\right)$ be trees of spaces. We say that a morphism $h: X \rightarrow X^{\prime}$ of these trees of spaces is a relative $K-q i$ embedding if for each $v \in V\left(T^{\prime}\right), e \in E\left(T^{\prime}\right)$, the map $h_{v}: X_{v}^{\prime} \rightarrow X_{v}, h_{e}: X_{e}^{\prime} \rightarrow X_{e}$ is a $K$-qi embedding. Similarly, one can define a relatively retractible morphism of trees of spaces (a morphism which admits a relative $L$-coarse Lipschitz retraction) as a morphism $h$ such that for each $v \in V\left(T^{\prime}\right), e \in E\left(T^{\prime}\right)$ the maps $h_{v}: X_{v}^{\prime} \rightarrow X_{v}, h_{e}: X_{e}^{\prime} \rightarrow X_{e}$ admit $L$-coarse Lipschitz left-inverses $h_{v}^{\prime}: X_{v} \rightarrow X_{v}^{\prime}, h_{e}: X_{e} \rightarrow X_{e}^{\prime}$. If $\mathfrak{X}, \mathfrak{X}^{\prime}$ are trees of $\delta$-hyperbolic spaces then the two notions are equivalent and, moreover, the subspaces $h_{v}\left(X_{v}^{\prime}\right) \subset X_{v}, h_{e}\left(X_{e}^{\prime}\right) \subset X_{e}$ are $\lambda$-quasiconvex for $\lambda=\lambda(L, \delta)$. Our goal is to prove that, under some conditions, a relatively retractive morphism is absolutely retractive, i.e. admits a coarse left-inverse $h^{\prime}$ : $X \rightarrow X^{\prime}$. (Recall that the morphism $h^{\prime}$ is a collection of maps $h_{v}^{\prime}: X_{v} \rightarrow X_{v}^{\prime}, h_{e}^{\prime}: X_{e} \rightarrow X_{e}^{\prime}$ satisfying certain compatibility properties.) This result is motivated by Mitra's construction of a coarse retraction in [Mit98, Theorem 3.8]. For relatively retractible morphisms of trees, by abusing the notation, we will identify the vertex/edge spaces $X_{v}^{\prime}, X_{e}^{\prime}$ of $\mathfrak{X}^{\prime}$ with their images $h_{v}\left(X_{v}^{\prime}\right) \subset X_{v}$ and $h_{e}\left(X_{e}^{\prime}\right) \subset X_{e}$ respectively.

The following theorem is inspired by Mitra's coarse retraction theorem in [Mit98, Theorem 3.8] and its proof closely follows Mitra's argument.

Theorem 2.21 (Existence of a retraction). Suppose that for some constants $C$, $D$, a relatively retractive morphism of trees of spaces $h: \mathfrak{X}^{\prime} \rightarrow \mathfrak{X}$ satisfies the following conditions:
(i) For every boundary edge e of $T^{\prime}, e=[v, w], v \in V\left(T^{\prime}\right), w \in V(T)-V\left(T^{\prime}\right)$,

$$
\operatorname{diam}_{X_{v}^{\prime}}\left(h_{v}^{\prime} \circ f_{e v}\left(X_{e}\right)\right) \leq D
$$

(ii) For every edge $[v, w]=e \in E\left(T^{\prime}\right)$

$$
\operatorname{dist}_{X_{v}^{\prime}}\left(h_{v}^{\prime} \circ f_{e v}, f_{e v}^{\prime} \circ h_{e}^{\prime}\right) \leq C
$$

Then the map $h: X^{\prime} \rightarrow X$ admits a coarse $L_{2.21}$-Lipschitz retraction $h^{\prime}: X \rightarrow X^{\prime}$ whose restriction to $X_{v}$ equals $h_{v}^{\prime}$ for each $v \in V\left(T^{\prime}\right)$. Here $L_{2.21}$ depends only on $C, D$, coarse Lipschitz constants of the maps $h_{v}^{\prime}, h_{e}^{\prime}$, and the parameters of trees of spaces $\mathfrak{X}, \mathfrak{X}^{\prime}$.

Proof. We let $K$ denote the maximum of Lipschitz constants of the projections $\pi$ : $X \rightarrow T, \pi^{\prime}: X^{\prime} \rightarrow T^{\prime}$. For each $v \in V\left(T^{\prime}\right)$ then we let $h^{\prime}(x):=h_{v}^{\prime}(x)$. Let $p: T \rightarrow T^{\prime}$ denote the nearest-point projection.

Suppose $x \in X_{w}, w \in V(T) \backslash V\left(T^{\prime}\right)$; then $v=p(w) \in T^{\prime}$ is the vertex nearest to $w$. Let $e \in E(T)$ be the edge incident to $v$ and contained in the geodesic $w v$. Thus, $e$ is a boundary edge of the subtree $T^{\prime} \subset T$. By the assumption (i), the projection $h_{v}^{\prime}\left(X_{e v}\right) \subset X_{v}^{\prime}$ has the diameter $\leq D$. We let $h^{\prime}(x)$ be any point $x^{\prime}$ of this projection (we will use the same point $x^{\prime}$ for all vertices $w$ in each component of $\left.T-T^{\prime}\right)$.

In order to verify that $h^{\prime}$ is (uniformly) coarse Lipschitz it suffices to find a uniform upper bound on distances $d\left(h^{\prime}(x), h^{\prime}(y)\right)$ for points

$$
x, y \in \mathcal{X}=\coprod_{v \in V(T)} X_{v}
$$

which are within distance $K$ from each other. If $x, y$ belong to the same vertex space $X_{v}$, then $d\left(h^{\prime}(x), h^{\prime}(y)\right) \leq L$, the upper bound for coarse Lipschitz constants of the maps $h_{v}^{\prime}: X_{v} \rightarrow X_{v}^{\prime}$. Suppose that $x, y$ belong to $X_{v}, X_{w}, v, w \in V\left(T^{\prime}\right)$ are vertices spanning an edge $e \in E\left(T^{\prime}\right)$. Then, necessarily,

$$
x \in X_{e v}, y \in X_{e w}, x=f_{e v}(z), y=f_{e w}(z)
$$

for some $z \in X_{e}$. The condition (ii) then implies the estimates

$$
d\left(h_{v}^{\prime}(x), f_{e v}^{\prime} \circ h_{e}^{\prime}(z)\right) \leq C, \quad d\left(h_{w}^{\prime}(y), f_{e w}^{\prime} \circ h_{e}^{\prime}(z)\right) \leq C
$$

hence $d\left(h^{\prime}(x), h^{\prime}(y)\right) \leq 2 C$.
If $v, w \in V(T)-V\left(T^{\prime}\right)$ then the inequality $d_{T}(v, w) \leq 1$ implies that $p(v)=p(w)=u \in$ $V\left(T^{\prime}\right)$ and there is a common boundary edge $e$ of $T^{\prime}$ contained in the geodesics $u v, u w \subset T$. In particular, both $h^{\prime}(x), h^{\prime}(y)$ belong to the subset

$$
h_{u}^{\prime} \circ f_{e u}\left(X_{e}\right) \subset X_{u}^{\prime}
$$

and, hence, $d\left(h^{\prime}(x), h^{\prime}(y)\right) \leq D$ by the condition (i).
Lastly, consider the case when $x \in X_{v}, y \in X_{w}$, where $v \in V\left(T^{\prime}\right), w \in V(T)-V\left(T^{\prime}\right)$ and $v, w$ span a boundary edge $e$ of $T^{\prime}$. Since $d(x, y) \leq 1$, it follows that $x \in X_{e v}, y \in X_{e w}$. Then $p(w)=v$ and, by the definition of $h^{\prime}, h^{\prime}(x), h^{\prime}(y) \in h_{v}^{\prime}\left(X_{e v}^{\prime}\right)$ and, therefore,

$$
d_{X_{v}^{\prime}}\left(h^{\prime}(x), h^{\prime}(y)\right) \leq D
$$

An easy corollary of Theorem 2.21 is:
Corollary 2.22. Suppose that $\mathfrak{X}=(\pi: X \rightarrow T)$ is a retractive tree of spaces. For every edge $e=[u, v] \in E(T)$ there exists an $r=r_{2.22}$-coarse retraction $X_{u v} \rightarrow X_{u}$, where $r$ depends only on the parameters of $\mathfrak{X}$ and its retractivity constant.

Proof. We have a retractive tree of spaces $\mathfrak{Y}=\left(\pi: X_{u v} \rightarrow \llbracket u, v \rrbracket\right)$. In $\mathfrak{Y}$ we have a subtree of spaces $\pi^{\prime}: \mathfrak{Y}^{\prime}=\left(Y^{\prime} \rightarrow \llbracket u, v \rrbracket\right)$, whose vertex spaces are $Y_{u}^{\prime}=Y_{u}=X_{u}, Y_{e}^{\prime}=$ $Y_{e}=X_{e}, Y_{v}^{\prime}=X_{e}, f_{e v}^{\prime}=\mathrm{id}, f_{e u}^{\prime}=f_{e u}$, and the morphism $h: \mathfrak{Y}^{\prime} \rightarrow \mathfrak{Y}$ is defined by using id $: Y_{u}^{\prime} \rightarrow Y_{u}$ and $f_{e v}: Y_{v}^{\prime} \rightarrow Y_{v}$. Since $\mathfrak{X}$ is retractive, the morphism $h$ is relatively retractive. Hence, by Theorem 2.21, the identity map $X_{u} \rightarrow X_{u}$ and the retraction $X_{v} \rightarrow X_{e}$ define a coarse Lipschitz retraction $Y_{u v} \rightarrow Y^{\prime}$. Since $Y^{\prime}$ is Hausdorff-close to $X_{u}$, we obtain a coarse Lipschitz retraction $Y_{u v} \rightarrow X_{u}$. The reader will verify that the coarse Lipschitz bound for this retraction depends only on the parameters of $\mathfrak{X}$ and its retractivity constant.

Another useful application of Theorem 2.21 is in the setting of trees of hyperbolic spaces (which we will discuss in more detail in the next section):

Corollary 2.23. Suppose that the trees of spaces $\mathfrak{X}, \mathfrak{X}^{\prime}$ and a morphism $\mathfrak{X}^{\prime} \rightarrow \mathfrak{X}$ which is a fiberwise L-qi embedding, have the following properties:

1. For some $\delta$, all vertex and edge-spaces $X_{v}, X_{e}$ are $\delta$-hyperbolic. (Accordingly, the images vertex and edge-spaces $h_{v}\left(X_{v}^{\prime}\right) \subset X_{v}, h_{e}^{\prime}\left(X_{e}^{\prime}\right) \subset X_{e}$ are $\lambda$-quasiconvex subsets in $X_{v}, X_{e}$ respectively, where $\lambda_{1.55}(\delta, L)$.)
2. The retractions $h_{v}^{\prime}, h_{e}^{\prime}$ are "nearest-point projections" in the sense that

$$
h_{v}^{\prime}=P_{X_{v}, X_{v}^{\prime}} \circ h_{v}, h_{e}^{\prime}=P_{X_{e}, X_{e}^{\prime}} \circ h_{e}
$$

3. There is constant $K$, for every edge $e=[v, w] \in T^{\prime}$ the Hausdorff distances $\operatorname{Hd}_{X^{\prime}}\left(X_{v}^{\prime}, X_{e}^{\prime}\right)$ and $\operatorname{Hd}_{X^{\prime}}\left(X_{w}^{\prime}, X_{e}^{\prime}\right)$ are $\leq K$.
4. $T^{\prime}=T$.

Then the fiberwise nearest point projections $h_{v}^{\prime}, h_{e}^{\prime}$ extend to an $L_{2.23}(\delta, L, K)$-coarse retraction $h^{\prime}: X \rightarrow X^{\prime}$, where (without loss of generality)

$$
L_{2.23}(\delta, L, K) \geq \max (L, K)
$$

Proof. For vertices $v$ in $T$ incident to an edge $e$, the images $h_{v}\left(X_{v}^{\prime}\right), f_{e v} \circ h_{e}\left(X_{e}^{\prime}\right)$ are uniformly Hausdorff-close to each other. Therefore, the nearest-point projections (in $X_{v}$ ) to these uniformly quasiconvex subsets are also uniformly close to each other (see Corollary 1.105). Now, the claim follows from Theorem 2.21.

### 2.4. Trees of hyperbolic spaces

We now introduce hyperbolicity conditions for trees of spaces.
Definition 2.24. A tree of spaces $\mathfrak{X}$ satisfies Axiom $\mathbf{H}$ if there are constants $\delta_{0}$ and $L_{0}$ such that:
(1) Each vertex/edge space $X_{v}, X_{e}$ of $\mathfrak{X}$ is a $\delta_{0}$-hyperbolic geodesic metric space.
(2) Each incidence map $f_{e v}: X_{e} \rightarrow X_{v}$ is an $L_{0}$-qi embedding. We will refer to such $\mathfrak{X}$ as a tree of hyperbolic spaces.

A finite graph of finitely generated groups $\mathcal{G}$ satisfies Axiom $\mathbf{H}$ if the the corresponding tree of spaces does. In other words, all vertex and edge-groups have to be hyperbolic and edge-groups are quasiconvex in the incident vertex-groups.

A word of caution: Our terminology does not mean that a tree of hyperbolic spaces $\mathfrak{X}=(\pi: X \rightarrow T)$ has $\delta$-hyperbolic total space $X$. Simple examples are given by Euclidean plane and Cayley complexes of Baumslag-Solitar groups. One needs to add a suitable flaring condition on $\mathfrak{X}$ to ensure hyperbolicity of $X$, as discussed in Section 2.5. Note also that our terminology requires not only uniform hyperbolicity of vertex and edge-spaces but also uniform qi embedding condition for the incidence maps.

Definition 2.25. We will refer to $\delta_{0}$ and $L_{0}$ as the primary parameters of a tree of hyperbolic spaces $\mathfrak{X}$.

In general, throughout the book, we will suppress the dependence of various constants and functions on the parameters of $\mathfrak{X}$.

Definition 2.26. Suppose that $\mathfrak{X}$ is a tree of hyperbolic spaces. Let $A, B \subset X$ with $\pi(A) \subset \pi(B)$. If $X_{v} \cap A$ and $X_{v} \cap B$ are uniformly quasiconvex in $X_{v}$ for all $v \in \pi(A)$, we define the nearest projections in $X_{v}$ of $A \cap X_{v}$ to $B \cap X_{v}$. This gives us a map $A \rightarrow B$. We refer to this map as the fiberwise projection of $A$ to $B$.

It is immediate that for every tree of hyperbolic spaces, for every edge $e=[v, w] \in$ $E(T)$, the subset $X_{e v} \subset X_{v}$ is $\lambda_{0}=\lambda_{1.90}\left(\delta_{0}, L_{0}\right)$-quasiconvex. In particular, every tree of hyperbolic spaces is retractive (see Definition 2.9) with retractions

$$
f_{v e}: X_{v} \rightarrow X_{e}, e=[v, w],
$$

given by the nearest-point projections $P=P_{X_{v}, X_{e v}}$ to the quasiconvex subsets $X_{e v}=f_{e v}\left(X_{e}\right) \subset$ $X_{v}$; more precisely: $f_{v e}(x)$ is defined to be an arbitrary point in $f_{e v}^{-1}(P(x))$.

As an application of Remark 2.18 or, alternatively, of Corollary 2.22, we obtain:

Lemma 2.27. Suppose that $\mathfrak{X}$ is a tree of hyperbolic spaces with the primary parameters $\delta$ and $L$. Then for every edge $e=[u, v] \in E(T)$, the inclusion maps $X_{u} \rightarrow X_{u v}, X_{v} \rightarrow$ $X_{u v}$ are $L_{0}^{\prime}=L_{2.27}(\delta, L)$-qi embeddings where $L_{0}^{\prime}$ is the maximum of 2 and of the coarse Lipschitz constant for a retraction $X_{u v} \rightarrow X_{v}$ (see Corollary 2.22).

Remark 2.28. In this lemma we ensured that $L_{0}^{\prime} \geq 2$. This, somewhat artificial, convention will be used in the proof of Lemma 2.37 below.

Suppose that $\mathfrak{X}^{\prime}=\left(\pi: X^{\prime} \rightarrow T\right)$ is a tree of hyperbolic spaces, $G<\operatorname{Isom}\left(X^{\prime}\right)$ is a subgroup acting by automorphisms of $\mathfrak{X}$, such that the quotient graph $T / G$ is finite and for every vertex $v \in V(T)$ (resp. edge $e \in E(T)$ ) the action of the corresponding stabilizer $G_{v}<$ $G$ (resp. $G_{e}<G$ ) on $X_{v}^{\prime}$ (resp. $X_{e}$ ) is quasiconvex (see Definition 1.129). Thus, the group $G$ also has structure of a graph of finitely generated groups $\mathcal{G}$ (with the underlying graph $T / G$ ); in particular, $G$ is finitely generated. (Note that we are not assuming hyperbolicity of the space $X$.)

Since $G$ acts via automorphisms of $\mathfrak{X}^{\prime}$, for each edge $e=[v, w] \in E(T)$ the subspace $X_{e v}^{\prime} \subset X_{v}^{\prime}$ is $G_{e}$-invariant. We will also assume that for each $v \in V(T)$ the $G_{v}$-orbit of $X_{e v}^{\prime}$ is locally finite in $X_{v}^{\prime}$ (see Definition 1.5). Note that the local finiteness assumption is automatic for instance if there exists a larger discrete group $G_{v}^{\prime}$ (containing $G_{v}$ ) acting on $X_{v}^{\prime}$ geometrically (Lemma 1.6).

Proposition 2.29. Under the above assumptions, there exists a coarse Lipschitz retraction $X^{\prime} \rightarrow G x$ for each $G$-orbit in $X^{\prime}$. In particular, each orbit map $G \rightarrow G x \subset X^{\prime}$ is a qi embedding.

Proof. The proof is similar to that of Corollary 2.23. Let $\mathfrak{X}=(\pi: X \rightarrow T)$ denote the tree of hyperbolic spaces corresponding to the graph of groups $\mathcal{G}$. The isometric action of $G$ via automorphisms of $\mathfrak{X}^{\prime}$ defines a morphism of trees of spaces $\mathfrak{X} \rightarrow \mathfrak{X}^{\prime}$. This morphism is relatively retractive in view of the quasiconvexity assumption for the actions $G_{v} \curvearrowright$ $X_{v}^{\prime}, G_{e} \curvearrowright X_{e}^{\prime}$. In view of Proposition 1.134(4), the local finiteness assumption implies that for $y \in X_{v}^{\prime}$, the restriction to $X_{e}^{\prime}$ of the nearest-point projection $P_{X_{v}^{\prime}, G_{y} y}$ is within uniformly bounded distance from the projection $P_{X_{e v}^{\prime}, G_{e} y}$. Thus, Theorem 2.21 applies and the coarse Lipschitz retractions $X_{v}^{\prime} \rightarrow X_{v}, X_{e}^{\prime} \rightarrow X_{e}$ together give rise to a coarse Lipschitz retraction $X^{\prime} \rightarrow X$. Since $G$ acts cocompactly on $X$, we, thus, obtain a coarse Lipschitz retraction $X^{\prime} \rightarrow G x$.

Corollary 2.30. Suppose that $\mathcal{G}^{\prime}$ is a finite, connected graph of hyperbolic groups satisfying Axiom $\mathbf{H}$, with $\pi_{1}\left(\mathcal{G}^{\prime}\right)=G^{\prime}$ and let $T$ be the Bass-Serre tree of $\mathcal{G}^{\prime}$. Let $G<G^{\prime}$ be a subgroup such that:

1. For every vertex $v$ (resp. edge e) of $T$, the $G$-stabilizer $G_{v}<G$ of $v$ (resp. the $G$ stabilizer $G_{e}<G$ of $e$ ) is a quasiconvex subgroup of the $G^{\prime}$-stabilizer $G_{v}^{\prime}<G^{\prime}$ of $v$ (resp. of the $G^{\prime}$-stabilizer $G_{e}^{\prime}<G^{\prime}$ of e).
2. The quotient-graph $T / G$ is finite.

There exists a coarse Lipschitz retraction $G^{\prime} \rightarrow G$. In particular, the subgroup $G$ is $q i$ embedded in $G^{\prime}$.

Example 2.31. Let $H=\pi_{1}\left(S_{1}\right) \star \pi_{1}\left(S_{2}\right)$, where $S_{1}, S_{2}$ are closed connected hyperbolic surfaces, and let $\phi_{i}: \pi_{1}\left(S_{i}\right) \rightarrow \pi_{1}\left(S_{i}\right), i=1,2$, be automorphisms. Then $\phi_{1}, \phi_{2}$ define an automorphism $\phi: H \rightarrow H$ and we obtain subgroups $G_{i}=\phi_{1}\left(S_{i}\right) \rtimes_{\phi_{i}} \mathbb{Z}$ in $G^{\prime}=H \rtimes_{\phi} \mathbb{Z}$. The subgroups $G_{i}<G^{\prime}$ clearly satisfy the assumptions of the corollary (where $T$ is the line) which implies that they are coarse Lipschitz retracts of $G^{\prime}$. Note, furthermore, that if $\phi_{1}, \phi_{2}$
are induced by pseudo-Anosov homeomorphisms of the surfaces $S_{1}, S_{2}$, then the group $G^{\prime}$ is isomorphic to the amalgam of hyperbolic groups $G_{1} \star_{\mathbb{Z}} G_{2}$, where $\mathbb{Z}$ is a malnormal subgroup of both $G_{1}, G_{2}$. Hence, the group $G^{\prime}$ is hyperbolic (see Corollary 2.53 below) and the subgroups $G_{1}, G_{2}$ are quasiconvex in $G^{\prime}$.

Below, $H$ is a quasiconvex subgroup of $G_{v}^{\prime}$ for some vertex $v$ in $T$.
Lemma 2.32. For each edge e and vertex $w$ in $T^{\prime}$, the $H$-stabilizer of e (resp. w) is a quasiconvex subgroup of $H$ and $G_{e}^{\prime}\left(\right.$ resp. $\left.G_{w}^{\prime}\right)$.

Proof. Consider first an edge $e=[v, w]$. Then $H_{e}=H \cap G_{e}^{\prime}$ is the intersection of two quasiconvex subgroups of $G_{v}^{\prime}$, hence, is quasiconvex in $G_{v}^{\prime}, G_{e}^{\prime}$ and $H$ (see Corollary 1.133). The general case follows from induction on the edge-path connecting $e$ (resp. w) to $v$.

Lemma 2.33. Suppose, in addition, that the $H$-stabilizers of edges incident to $v$ are all finite. Then for each $R \geq 0, x \in X_{v}^{\prime}$ and all the edges e incident to $v$, the coarse intersections intersections $H x \cap N_{R}\left(X_{e v}^{\prime}\right)$ are uniformly bounded, with bound independent of $e$. In other words, the pairs $H x, X_{e}^{\prime}$ are uniformly cobounded.

Proof. By properness of the action, there exists an edge $e$ incident to $v$ such that the diameter of the intersection $H x \cap N_{R}\left(X_{e v}^{\prime}\right)$ is maximal. The subset $X_{e v}^{\prime}$ is Hausdorff-close to the orbit $G_{e}^{\prime} x$. According to Proposition 1.134, the coarse intersection $H x \cap N_{R}\left(X_{e v}^{\prime}\right)$ is Hausdorff-close to the orbit $H_{e} x$, where $H_{e}=H \cap G_{e}^{\prime}$. Since, by the hypothesis of the lemma, the subgroup $H_{e}$ is finite, the coarse intersection $H x \cap N_{R}\left(X_{e v}^{\prime}\right)$ is bounded.

Corollary 2.34. If the pair $H x, X_{e}^{\prime}$ is not cobounded then the intersection $H \cap G_{e}^{\prime}$ is infinite.

We will prove in Corollary 2.63 that there exists a function $\delta(n)$ (depending also on the constants $\delta_{0}$ and $L_{0}$ ) such that for each interval $J$ of length $n$, the pull-back space $X_{J}^{\prime}$ (with its intrinsic path-metric) is $\delta(n)$-hyperbolic. Thus, we can talk about cobounded pairs of subspaces in vertex-spaces $X_{v}^{\prime}, X_{w}^{\prime}, v, w \in V(J)$.

Continuing with the notation of Lemma 2.33, and applying Corollary 2.34 inductively (with Lemma 2.32), we obtain:

Lemma 2.35. Suppose that for some vertex $w \in T, x \in X_{v}^{\prime}$, the subsets $H x, X_{w}^{\prime}$ are not cobounded in $X_{J}^{\prime}, J=\llbracket v, w \rrbracket$. Then the $H$-stabilizer of the segment $J$ is an infinite subgroup of $H$.

Below are few more easy consequences of Axiom $\mathbf{H}$ for trees of spaces.
Lemma 2.36. Assume that $\mathfrak{F}$ is a tree of hyperbolic spaces. Then for every edge $e=$ $\left[v_{1}, v_{2}\right]$ of $T$, if $\alpha_{i}=\left[x_{i} y_{i}\right]_{\nu_{v_{i}}} \subset X_{v_{i}}$ are vertical geodesics such that

$$
d_{X_{v_{1} v_{2}}}\left(x_{1}, x_{2}\right) \leq C, \quad d_{X_{v_{1} v_{2}}}\left(y_{1}, y_{2}\right) \leq C,
$$

then the Hausdorff distance between these vertical geodesics in $X_{v_{1} v_{2}}$ is at most $C_{1}=$ $C_{2.36}(C)$.

Proof. Geodesics $x_{1} x_{2}, y_{1} y_{2}$ have to cross $X_{e}\left(\right.$ separating $\left.X_{\nu w}\right)$ at some points $x, y \in X_{e}$. Since both $X_{e v_{i}} \subset X_{v_{i}}$ are $\lambda_{0}$-quasiconvex, it follows that geodesics $\alpha_{i}$ lie in $N_{\lambda_{0}}\left(X_{e v_{i}}\right)$, $i=1,2$. Lemma 1.54 applied to the geodesic $\alpha_{i}$ and the $L_{0}$-quasigeodesic $\alpha_{i}^{\prime}=f_{e v_{i}}\left([x y]_{X_{e}}\right)$ implies that

$$
\operatorname{Hd}_{X_{v_{i}}}\left(\alpha_{i}, f_{e v_{i}}(\alpha)\right) \leq D=D_{1.54}\left(\delta_{0}, L_{0}, C\right)
$$

Since

$$
\operatorname{Hd}_{X_{v_{1} v_{2}}}\left(\alpha, f_{e v_{i}}(\alpha)\right) \leq 1
$$

we conclude:

$$
\operatorname{Hd}_{X_{v_{1} v_{2}}}\left(\alpha_{1}, \alpha_{2}\right) \leq 2(1+D)
$$

Lemma 2.37. Let $I=\llbracket v, w \rrbracket \subset T$ be a subinterval, we denote its consecutive vertices $v_{0}=v, v_{1}, \ldots, v_{n}=w$. Let $\gamma_{0}, \gamma_{1}$ be K-qi sections over I. Then the function

$$
\ell(i):=d_{X_{i}}\left(\gamma_{0, k}\left(v_{i}\right), \gamma_{1, k}\left(v_{i}\right)\right), i \in[0, n] \cap \mathbb{Z}
$$

satisfies

$$
\ell(n) \leq a^{n} \ell(0)+\frac{a^{n}-1}{a-1} b<a^{n}(\ell(0)+b)
$$

where $a=L_{0}^{\prime}, b=2 L_{0}^{\prime} K$.
Proof. Consider an edge $e=\left[v_{i}, v_{i+1}\right] \subset I$. The points

$$
\gamma_{0}\left(v_{i+1}\right), \gamma_{1}\left(v_{i+1}\right) \in X_{v_{i}}
$$

are connected by a path of length $\leq 2 K+\ell(i)$ in $X_{\llbracket v_{i}, v_{i+1} \rrbracket}$, obtained by concatenating a vertical geodesic $\left[\gamma_{0}\left(v_{i}\right) \gamma_{1}\left(v_{i}\right)\right]_{X_{v_{i}}}$ with two geodesics of length $\leq K$. Since $X_{v_{i+1}}$ is $L_{0}^{\prime}$-qi embedded in $X_{\llbracket v_{i}, v_{i+1} \rrbracket}$, we have

$$
\ell(i+1) \leq L_{0}^{\prime}(2 K+\ell(i))
$$

Then

$$
\ell(n) \leq a^{n} \ell(0)+\left(a^{n-1}+\ldots+1\right) b=a^{n} \ell(0)+\frac{a^{n}-1}{a-1} b<a^{n}(\ell(0)+b)
$$

Corollary 2.38. If $\ell(0) \geq a(M+b)$, then for all

$$
n \in[0, N], N=\left\lfloor\log _{a}\left(\frac{\ell(0)}{M+b}\right)\right\rfloor,
$$

we have

$$
\ell(n)>M .
$$

Proof. We first reverse the role of $\ell(0)$ and $\ell(n)$ and obtain from the lemma that

$$
\ell(n)<a^{-n} \ell(0)-b, n \in \mathbb{N}
$$

The inequality $\ell(n)>M$ then follows from

$$
n \leq N \leq \log _{a}\left(\frac{\ell(0)}{M+b}\right)
$$

The assumption that $\ell(0) \geq a(M+b)$ ensures that $N \geq 1$.
Another corollary (or, rather, a special case of the lemma) is
Corollary 2.39. For every edge $e=[u, v]$ in $T$, any pair points $x, y \in X_{u}$, and a pair of $K$-qi sections $\gamma_{0}, \gamma_{1}$ over the interval uv, we have

$$
d_{X_{v}}\left(\gamma_{0}(v), \gamma_{1}(v)\right) \leq D_{2.39}\left(K, d_{X_{u}}(x, y)\right)=L_{0}^{\prime}\left(2 K+d_{X_{u}}(x, y)\right)
$$

### 2.5. Flaring

Geodesics (and, hence, uniform quasigeodesics) in hyperbolic spaces diverge (exponentially fast). Since $k$-qi leaves in hyperbolic trees of spaces $\pi: X \rightarrow T$ are uniform quasigeodesics, they should also diverge if $X$ is hyperbolic. In this section we discuss several divergence conditions, called flaring conditions ${ }^{4}$, one can impose on qi-leaves in trees

[^6]of spaces. These conditions involve pairs $\Pi=\left(\gamma_{0}, \gamma_{1}\right)$ of $k$-sections $\gamma_{0}, \gamma_{1}$ over a common geodesic segment $J=\llbracket t_{-n}, t_{n} \rrbracket \subset T$ of length $2 n$ and prescribe the nature of growth of the vertical distances
$$
d_{X_{v_{i}}}\left(\gamma_{0}\left(v_{i}\right), \gamma_{1}\left(v_{i}\right)\right)
$$
for $i>0$ or $i<0$. The girth $\Pi_{0}$ of the pair $\left(\gamma_{0}, \gamma_{1}\right)$ is the vertical distance
$$
d_{X_{0}}\left(\gamma_{0}(0), \gamma_{1}(0)\right)
$$

Remark 2.40. $\Pi_{0}$ need not be equal to

$$
\min _{v \in V(J)} d_{X_{v}}\left(\gamma_{0}(v), \gamma_{1}(v)\right) .
$$

We will frequently use the notation $\Pi_{\max }$ for the maximal separation of the ends of the pair $\Pi=\left(\gamma_{0}, \gamma_{1}\right)$,

$$
\Pi_{\max }:=\max \left(d_{X_{t_{-n}}}\left(\gamma_{0}\left(t_{-n}\right), \gamma_{1}\left(t_{-n}\right)\right), d_{X_{t_{n}}}\left(\gamma_{0}\left(t_{n}\right), \gamma_{1}\left(t_{n}\right)\right)\right),
$$

describing the rate of growth of the above vertical distances (in one of the directions).

Figure 2. Flaring.
2.5.1. Proper and uniform flaring conditions. The proper flaring condition requires $k$-qi sections over the same geodesic in $T$ to diverge at some uniform rate in at least one direction. More precisely:

Definition 2.41 (Proper flaring). A tree of spaces $\mathfrak{X}=(\pi: X \rightarrow T)$ is said to satisfy the proper $\kappa$-flaring condition if there exists $m_{\kappa} \geq 0$ and a positive proper function $\phi_{\kappa}: \mathbb{N} \rightarrow \mathbb{R}_{+}$ such that for every pair $\Pi$ of $\kappa$-qi sections $\gamma_{0}, \gamma_{1}$ of girth $>m_{\kappa}$, over an interval of length $2 n$ in $T$, we have

$$
\Pi_{\max } \geq \phi_{\kappa}(n)
$$

In other words, $\kappa$-sections have to diverge uniformly fast but the rate of divergence is allowed to be, say, sublinear (unlike the the Bestvina-Feighn flaring condition where one has an exponential rate of flaring).

It is clear from the definition that if $\mathfrak{X}$ satisfies the proper $K$-flaring condition, then it also satisfies the $\kappa$-flaring condition for all $\kappa \in[1, K]$ : We simply take $\phi_{\kappa}:=\phi_{K}$ and $m_{\kappa}:=m_{K}$.

Note also that it would be too much to ask for

$$
\Pi_{\min }=\min \left(d_{X_{-m}}\left(\gamma_{0}(-m), \gamma_{1}(-m)\right), d_{X_{n}}\left(\gamma_{0}(n), \gamma_{1}(n)\right)\right) \geq \phi_{\kappa}(n),
$$

for some (uniform) proper function $\phi_{\kappa}$.
Definition 2.42. We will say that a pair $\Pi=\left(\gamma_{0}, \gamma_{1}\right)$ of sections over an interval $\llbracket-N, N \rrbracket$ in $T$ is flaring in the positive/negative direction if, respectively,

$$
d_{X_{n}}\left(\gamma_{0}(n), \gamma_{1}(n)\right) \geq \phi_{\kappa}(n)
$$

or

$$
d_{X_{-n}}\left(\gamma_{0}(-n), \gamma_{1}(-n)\right) \geq \phi_{\kappa}(n)
$$

for all $n \in \mathbb{N} \cap[1, N]$.
We will see in Lemma 2.55 and Corollary 2.57, that proper flaring (for all $\kappa \geq 1$ ) implies proper flaring in positive or negative direction (after a possible change of the function $\phi_{\kappa}$ ).

In the book we will be mostly using an alternative form of the proper flaring condition established in the next proposition. For the ease of the notation, in this section we will identify a geodesic, say $\llbracket v, w \rrbracket$, of length $\ell$ in $T$, where $v, w \in V(T)$ with an interval $[a, b] \subset$ $\mathbb{R}$ of length $\ell$, where $a, b \in \mathbb{Z}$ through an implicit isometry $[a, b] \rightarrow \llbracket v, w \rrbracket$; this means, in particular, that integers correspond to the vertices in $\llbracket v, w \rrbracket$.

Proposition 2.43. The following are equivalent:

1. A tree of spaces $\mathfrak{X}=(\pi: X \rightarrow T)$ satisfies the proper $\kappa$-flaring condition.
2. There exist $M_{\kappa}$ such that for all $D \geq 0$, there is $\tau=\tau_{2.43}(\kappa, D)$ satisfying the following:

For every pair $\Pi$ of $\kappa$-qi sections $\gamma_{0}, \gamma_{1}$ over a geodesic interval $[-m, n] \subset T(m, n \in$ $\mathbb{N}$ ), if

$$
d_{X_{i}}\left(\gamma_{1}(i), \gamma_{2}(i)\right)>M_{\kappa}, \forall i \in[-m+1, n-1]
$$

and

$$
\Pi_{\max }=\max \left(d_{X_{-m}}\left(\gamma_{0}(-m), \gamma_{1}(-m)\right), d_{X_{n}}\left(\gamma_{0}(n), \gamma_{1}(n)\right)\right) \leq D,
$$

then

$$
n+m \leq \tau
$$

Proof. First of all, we leave it to the reader to check that if (2) holds for all $m=n$ then it holds for all $m, n \in \mathbb{N}$. Therefore, in what follows, in (2) we will be always assuming that $n=m$.
i. Assume that the proper flaring condition holds. Take $M_{\kappa}:=m_{\kappa}$ and consider a pair $\Pi=\left(\gamma_{0}, \gamma_{1}\right)$ of $\kappa$-qi sections over an interval $[-n, n] \subset T$ as in part (2). In particular, girth of $\left(\gamma_{0}, \gamma_{1}\right)$ is $>M_{\kappa}$. By the proper flaring condition, we have

$$
D \geq \Pi_{\max } \geq \phi_{\kappa}(n) .
$$

Since $\phi_{\kappa}(t)$ is proper, the preimage $\phi_{\kappa}^{-1}([0, D])$ is contained in an interval $\left[0, t_{\kappa, D}\right]$. Then we take

$$
\tau(\kappa, D):=2 t_{\kappa, D}
$$

ii. Conversely, suppose that (2) holds but proper flaring fails. Then there exist a constant $D>0$ and a sequence $\Pi^{m}$ of pairs of $\kappa$-qi sections $\gamma_{0}^{m}, \gamma_{1}^{m}$ over some intervals $\llbracket s_{m}, t_{m} \rrbracket \subset T$ of length $2 n_{m}$ with the midpoint vertex $r_{m}$ such that $\Pi_{0}^{m} \rightarrow \infty, n_{m} \rightarrow \infty$, but

$$
\Pi_{\max }^{m}=\max \left(d_{X_{t_{m}}}\left(\gamma_{0}^{m}\left(t_{m}\right), \gamma_{1}^{m}\left(t_{m}\right)\right), d_{X_{s_{m}}}\left(\gamma_{0}^{m}\left(s_{m}\right), \gamma_{1}^{m}\left(s_{m}\right)\right)\right) \leq D
$$

We will isometrically parameterize the geodesic $\left[s_{m}, t_{m}\right]$ by the interval $\left[-n_{m}, n_{m}\right] \subset \mathbb{Z}$ so that $r_{m}$ corresponds to 0 . Set $\tau:=\tau(\kappa, M)$ where

$$
M=\max \left(D, M_{\kappa}\right)
$$

Define the function

$$
\ell_{m}(i):=d_{X_{i}}\left(\gamma_{0}^{m}(i), \gamma_{1}^{m}(i)\right), i \in\left[-n_{m}, n_{m}\right] ; \ell_{m}(0)=\Pi_{0}^{m}
$$

Then for sufficiently large $m$ we have

$$
\Pi_{0}^{m}=\ell_{m}(0)>a(M+b) ; a=L_{0}^{\prime}, b=2 L_{0}^{\prime} \kappa
$$

and, hence, according to Corollary 2.38, for all $n \in\left[-N_{m}+1, N_{m}-1\right]$, we have

$$
\ell_{m}(n)>M
$$

Here

$$
N_{m}=\left\lfloor\log _{a}\left(\frac{\Pi_{0}^{m}}{M+b}\right)\right\rfloor .
$$

Observe that the right hand side diverges to infinity as $m \rightarrow \infty$. Therefore, for sufficiently large $m, N_{m}>\tau / 2$. Thus, we obtain a contradiction with (2).

While the proper flaring condition is quite natural, it is the condition (2) in the proposition that we will use throughout the book.

Definition 2.44. We will say that a tree of spaces $\mathfrak{X}$ satisfies the uniform $\kappa$-flaring condition with the parameter $M_{\kappa}$ if the condition (2) in the proposition holds.

Convention 2.45. In what follows, unless indicated otherwise, $\kappa$-flaring always means uniform $\kappa$-flaring.

Lemma 2.46. Suppose that $\mathfrak{X}=(\pi: X \rightarrow T)$ is a tree of hyperbolic spaces with $\delta$-hyperbolic total space $X$. Then $\mathfrak{X}$ satisfies the uniform $\kappa$-flaring condition for all $\kappa \geq 1$.

Proof. As noted earlier, it suffices to consider the case $n=m$. Since $\gamma_{0}, \gamma_{1}$ are $\kappa$ quasigeodesics in $X$, they are within Hausdorff distance $D_{1.53}(\delta, \kappa)$ from geodesics $\gamma_{i}^{*}$ in $X$ connecting the endpoints of $g a_{0}, \gamma_{1}$ respectively. Take $x_{0}=\gamma_{0}(0)$ and $x_{0}^{*} \in \gamma_{0}^{*}$ a point within distance $D_{1.53}(\delta, \kappa)$ from $x_{0}$. The projections to $T$ of the geodesics $\left[\gamma_{0}(-n) \gamma_{1}(-n)\right]_{X}$, $\left[\gamma_{0}(n) \gamma_{1}(n)\right]_{X}$ each have length $\leq D$. Thus,

$$
d\left(x_{0}^{*},\left[\gamma_{0}( \pm n) \gamma_{1}( \pm n)\right]_{X}\right) \geq D
$$

Suppose for a moment that $n-D>2 \delta$. By the slim quadrilateral property, there is a point $x_{1}^{*} \in \gamma_{1}^{*}$ within distance $2 \delta$ from $x_{0}^{*}$. (A priori, this could have been a point on one of two other sides of the geodesic quadrilateral with the vertices $\gamma_{i}( \pm n), i=0,1$, but this possibility is ruled out by our assumption that $n-D>2 \delta$.) Thus, we find a point $x_{1} \in \gamma_{1} \cap X_{v}$, within distance

$$
D_{0}=2\left(\delta+D_{1.53}(\delta, \kappa)\right)+\kappa
$$

from $x_{0}$. While $v$ need not be equal to the vertex $0 \in \llbracket-n, n \rrbracket \subset T$, we still have

$$
d_{T}(0, v) \leq D_{0}
$$

In particular,

$$
d_{X_{0}}\left(\gamma_{0}(0), \gamma_{1}(0)\right)=\Pi_{0} \geq d_{X}\left(\gamma_{0}(0), \gamma_{1}(0)\right) \leq D_{1}=D_{0}(\kappa+1)
$$

We, therefore, set

$$
M_{\kappa}=D_{1}
$$

and $\tau(\kappa, D)=\delta+\frac{1}{2} D$. Since in the uniform $\kappa$-flaring property, it is assumed, in particular, that

$$
d_{X_{0}}\left(\gamma_{0}(0), \gamma_{1}(0)\right)>M_{\kappa},
$$

we obtain a contradiction with the above estimates, unless the inequality $n-D \geq 2 \delta$ is violated, i.e. unless $n \leq D+2 \delta$, equivalently, the length of the interval $\llbracket-n, n \rrbracket$ is at most $\tau$, as required.

The uniform flaring condition has an immediate consequence that we will use on few occasions:

Lemma 2.47 (Three flows lemma). Suppose that $\pi: X \rightarrow T$ satisfies the uniform $K$ flaring condition. Suppose that $\gamma_{1}, \gamma_{2}, \gamma_{3}$ are $K$-qi sections of $\pi: X \rightarrow T$ over an interval $\llbracket s, t \rrbracket$ such that for all $r \in \rrbracket s, t \llbracket$,

$$
d_{X_{r}}\left(\gamma_{1}(r), \gamma_{3}(r)\right)>M_{K}
$$

while

$$
\max _{i, j} d_{X_{s}}\left(\gamma_{i}(s), \gamma_{j}(s)\right) \leq C, \quad \max _{i, j} d_{X_{t}}\left(\gamma_{i}(t), \gamma_{j}(t)\right) \leq C .
$$

Then the length of the interval $\llbracket s, t \rrbracket$ is uniformly bounded, i.e is $\leq \tau_{2.47}(K, C)$.
The property appearing below will be also used quite often in our book:
Definition 2.48. We say that a tree of spaces $\mathfrak{X}$ satisfies the $R(K, C)$-thin K-bigon property if there is a function $R(K, C)$ such that for every pair $\Pi=\left(\gamma_{1}, \gamma_{2}\right)$ of $K$-qi sections of $\pi: X \rightarrow T$ over any interval $I=\llbracket v, w \rrbracket$,

$$
\Pi_{\max } \leq C \Rightarrow \quad \forall t \in V(I), d_{X_{t}}\left(\gamma_{1}(t), \gamma_{2}(t)\right) \leq R(K, C) .
$$

Here, as before,

$$
\Pi_{\max }=\max \left(d_{X_{v}}\left(\gamma_{1}(v), \gamma_{2}(v)\right), d_{X_{w}}\left(\gamma_{1}(w), \gamma_{2}(w)\right)\right) .
$$

Corollary 2.49. Aa tree of spaces $\mathfrak{X}=(X \rightarrow T)$ satisfies the uniform $K$-flaring condition if and only if it satisfies the $R(K, C)$-thin $K$-bigon property for some $R(K, C)=$ $R_{2.49}(K, C)$.

Proof. 1. Assume that $\mathfrak{X}$ satisfies the uniform $K$-flaring condition. Consider a pair of $K$-qi sections over an interval $I \subset T$. If for every vertex $t \in I, d_{X_{t}}\left(\gamma_{1}(t), \gamma_{2}(t)\right) \leq M_{K}$, then we are done. Otherwise, let $I^{\prime}=\llbracket v^{\prime}, w^{\prime} \rrbracket \subset \llbracket v, w \rrbracket$ be a maximal subinterval such that for all vertices $t \in I^{\prime}$ we have

$$
d_{X_{t}}\left(\gamma_{1}(t), \gamma_{2}(t)\right)>M_{K} .
$$

Then there are edges $\left[v^{\prime \prime}, v^{\prime}\right],\left[w^{\prime}, w^{\prime \prime}\right]$ in $I$ (not contained in $I^{\prime}$ ) such that

$$
d_{X_{s}}\left(\gamma_{1}(s), \gamma_{2}(s)\right) \leq C^{\prime}:=\max \left(M_{K}, C, 3 \delta_{0}\right), s \in\left\{v^{\prime \prime}, w^{\prime \prime}\right\}
$$

By Lemma 2.47 applied to $K$-qi sections $\gamma_{1}, \gamma_{2}=\gamma_{3}$, restricted to $I^{\prime \prime}:=\llbracket v^{\prime \prime}, w^{\prime \prime} \rrbracket$, we obtain:

$$
d_{T}\left(v^{\prime \prime}, w^{\prime \prime}\right) \leq \tau:=\tau_{2.47}\left(K, C^{\prime}\right) .
$$

By Lemma 2.37, we get that for all $t \in V\left(I^{\prime}\right)$,

$$
d_{X_{t}}\left(\gamma_{1}(t), \gamma_{2}(t)\right) \leq R_{2.49}(K, C):=a^{\tau}\left(C^{\prime}+\frac{b}{a-1}\right),
$$

with $a=L_{0}^{\prime}, b=2 L_{0}^{\prime} K$. (Recall that $L_{0}^{\prime} \geq 2$.)
2. We argue as in the proof of Proposition 2.43. Suppose that proper $\kappa$-flaring fails. Then there exist a constant $D>0$ and a sequence $\Pi^{m}$ of pairs of $\kappa$-qi sections $\gamma_{0}^{m}, \gamma_{1}^{m}$ over
some intervals $J_{m}=\llbracket s_{m}, t_{m} \rrbracket \subset T$ of length $2 n_{m}$ with the midpoint vertex $r_{m}$ such that $\Pi_{0}^{m} \rightarrow \infty, n_{m} \rightarrow \infty$, but

$$
\Pi_{\max }^{m}=\max \left(d_{X_{t_{m}}}\left(\gamma_{0, m}\left(t_{m}\right), \gamma_{1, m}\left(t_{m}\right)\right), d_{X_{s_{m}}}\left(\gamma_{0, m}\left(s_{m}\right), \gamma_{1, m}\left(s_{m}\right)\right)\right) \leq D
$$

Setting $C:=D$, the hypothesis in Part 2 of the corollary means that

$$
d_{X_{t}}\left(\gamma_{1}(t), \gamma_{2}(t)\right) \leq R(K, C)
$$

for all vertices $t \in J_{m}$. This contradicts $\Pi_{0}^{m} \rightarrow \infty$.
2.5.2. Acylindrical trees of spaces. An easy, and frequently occurring, sufficient condition for uniform $\kappa$-flaring is acylindricity:

Definition 2.50. Fix constants $\kappa \geq 1$ and $\tau \geq 1$. A tree of spaces ( $\pi: X \rightarrow T$ ) is $(M, \kappa, \tau)$-acylindrical if for every pair of $\kappa$-sections $\gamma_{0}, \gamma_{1}$ over an interval $J \subset T$ of length $\geq \tau$, we have

$$
d_{X_{v}}\left(\gamma_{0}(t), \gamma_{1}(t)\right) \leq M, \forall t \in V(J) .
$$

We give few geometric examples of acylindrical trees of spaces in Section 2.6.2. In order to see that acylindrical trees of spaces satisfy uniform flaring, we take $M_{\kappa}:=M$ and $\tau(\kappa, D):=\tau+2$. Then, regardless of $D$, if $\Pi=\left(\gamma_{0}, \gamma_{1}\right)$ is a pair of $\kappa$-qi sections over an interval $J=\llbracket u, v \rrbracket \subset T$ and

$$
d_{X_{i}}\left(\gamma_{1}(i), \gamma_{2}(i)\right)>M, i \in V(\rrbracket u, v \llbracket),
$$

then the length of $\rrbracket u, v \llbracket$ is $<\tau$ and, hence, $J$ has length $<\tau(\kappa, D)=\tau+2$.
The terminology acylindrical has its origin in 3-dimensional topology: A compact oriented 3-dimensional manifold with incompressible boundary $M$ is called (homotopically) acylindrical if every map of an annulus $(A, \partial A) \rightarrow(M, \partial M)$ is homotopic (rel. $\partial A$ ) to a map $A \rightarrow \partial M$. Algebraically speaking, this condition means that if two elements of $\pi_{1}(\partial M, m)$ are conjugate in $\pi_{1}(M, m)$, then they are conjugate in $\pi_{1}(\partial M, m)$. If one glues two connected acylindrical 3-manifolds $M_{1}, M_{2}$ along their boundary surfaces to form a 3-manifold $M$, then every subgroup of $\pi_{1}(M)$ isomorphic to $\mathbb{Z}^{2}$ is contained (up to conjugation) in $\pi_{1}\left(M_{1}\right)$ or in $\pi_{1}\left(M_{2}\right)$. Algebraically speaking, topological acylindricity corresponds to acylindricity in the sense of group actions on trees (Definition 2.4) as follows. The decomposition $M=M_{1} \cup M_{2}$ yields graph-of-groups decomposition of the fundamental $G=\pi_{1}(M)$. Let $G \times T \rightarrow T$ denote the action of $G$ on the Bass-Serre tree $T$ corresponding to this decomposition of $G$. Then the action of $G$ on $T$ is 1 -acylindrical if and only if both manifolds $M_{1}, M_{2}$ are acylindrical. Suppose again that $G$ is the fundamental group of a finite graph of finitely generated groups $(\mathcal{G}, Y)$; let $G \times T \rightarrow T$ be the corresponding $G$-action on the Bass-Serre tree and $\mathfrak{X}=(X \rightarrow T)$ the tree of spaces with $X$ equal to the Cayley graph of $G$ as discussed in Example 2.16. We will see in Proposition 2.51 that in this setting the tree of spaces $\mathfrak{X}$ is $(\kappa, \tau)$-acylindrical provided that the action of $G$ on $T$ is $k$-acylindrical for suitable values of $\kappa, \tau$ and $k$.
2.5.3. Group-theoretic examples. The following proposition was proved by Ilya Kapovich [Kap01]; below, we give a different proof.

Proposition 2.51. Suppose $(\mathcal{G}, Y)$ is a finite graph of hyperbolic groups satisfying Axiom $\mathbf{H}$ and $G:=\pi_{1}(\mathcal{G})$. If the $G$-action on the Bass-Serre tree $T$ of $\mathcal{G}$ is $R$-acylindrical in the sense of Sela [Sel97], then for all $\kappa \geq 1$ there is a constant $M_{\kappa}$ such that the induced tree of metric spaces $\mathfrak{X}=(\pi: X \rightarrow T)$ is $\left(M_{\kappa}, \kappa, R\right)$-acylindrical. In particular, in view Theorem 2.58, $G$ is hyperbolic.

Proof. The first part of the proof follows in the arguments in [Sar18, Section 3]. We will need some properties of the tree of spaces $\mathfrak{X}$ listed below.
(1) The vertex-spaces of $\mathfrak{X}$ are metric graphs which are isometric copies of various cosets of $G_{y}$ 's in $G$, where $y \in V(Y)$. The map $\pi: X \rightarrow T$ is $G$-equivariant. The $G$ action on $X$ is proper and cocompact, and the stabilizer of each $v \in V(T)$ acts on $V\left(X_{v}\right)$ transitively.
(2) Suppose that $\Gamma$ is a Cayley graph of $G$ with respect to a finite generating set. Let $f: G \rightarrow X$ be an orbit map. We know that for each $y \in V(Y)$ and $g \in G, g G_{y}$ is a vertex of $T$. We have $\operatorname{Hd}\left(X_{g V_{y}}, f\left(g G_{y}\right)\right) \leq D$, where $D$ is a constant independent of $g \in G, y \in V(Y)$.

Suppose that the claim of the proposition fails for some $\kappa$. Then there is a sequence of pairs of $\kappa$-qi sections $\gamma_{0, n}, \gamma_{1, n}$ over geodesic intervals

$$
\beta_{n}:[0, R+1] \rightarrow T
$$

of length $R+1$, such that for some integer $t \in[0, R+1]$ we have

$$
d_{X_{\beta_{n}(t)}}\left(\gamma_{0, n}(t), \gamma_{1, n}(t)\right) \geq n, \quad \forall n \in \mathbb{N} .
$$

Note that for all integers $s \in[0, R+1]$

$$
d_{X}\left(\gamma_{0, n}(s), \gamma_{1, n}(s)\right) \geq d_{X}\left(\gamma_{0, n}(t), \gamma_{1, n}(t)\right)-d_{X}\left(\gamma_{0, n}(s), \gamma_{0, n}(t)\right)-d_{X}\left(\gamma_{1, n}(s), \gamma_{1, n}(t)\right)
$$

Since $\gamma_{0, n}, \gamma_{1, n}$ are $\kappa$-qi sections, we have

$$
\begin{aligned}
d_{X}\left(\gamma_{0, n}(s), \gamma_{1, n}(s)\right) \geq & d_{X}\left(\gamma_{0, n}(t), \gamma_{1, n}(t)\right)-2 \kappa|s-t|-2 \kappa \geq \\
& d_{X}\left(\gamma_{0, n}(t), \gamma_{1, n}(t)\right)-2(R+1) \kappa-2 \kappa
\end{aligned}
$$

Since vertex-spaces of $\mathfrak{X}$ are uniformly properly embedded in the ambient space $X$ we see that $d_{X}\left(\gamma_{0, n}(t), \gamma_{1, n}(t)\right) \rightarrow \infty$ as $n \rightarrow \infty$. Thus, $d_{X}\left(\gamma_{0, n}(t), \gamma_{1, n}(t)\right) \rightarrow \infty$, which in turn implies that $d_{X_{\beta_{n}(s)}}\left(\gamma_{0, n}(s), \gamma_{1, n}(s)\right) \rightarrow \infty$ for all $s \in[0, R+1]$. Thus, passing to subsequence, if necessary, we may assume that $d_{X_{\beta_{n}(s)}}\left(\gamma_{0, n}(s), \gamma_{1, n}(s)\right) \geq n$ for all $n \in \mathbb{N}$ and $s \in[0, R+1]$. Also, since the group $G$ acts on $T$ cocompactly, we can assume, by passing to subsequence if necessary, that $\beta_{n}(0)$ is a fixed vertex $v$ and $\gamma_{0, n}(0)$ is a fixed point $x \in X_{v}$. Since $X$ is quasiisometric to $G$, by passing to a further subsequence, if necessary, we may assume that $\beta_{n}$ is a fixed geodesic $v w$ in $T$, where $d_{T}(v, w)=R+1$. We note that since $d_{X}\left(\gamma_{0, n}(v), \gamma_{1, n}(w)\right) \leq \kappa+\kappa R$, by Lemma 2.36 we have

$$
\operatorname{Hd}\left(\left[\gamma_{0, n}(v) \gamma_{1, n}(v)\right]_{X_{v}},\left[\gamma_{0, n}(w) \gamma_{1, n}(w)\right]_{X_{v}}\right) \leq C_{2.36}(\kappa+(R+1) \kappa)
$$

Now, by (2) above we have a constant $D_{1}$ and $y, y^{\prime} \in V(Y), g, g^{\prime} \in G$ such that
(i) $v=g G_{y}, w=g^{\prime} G_{y^{\prime}}$ and
(ii) the diameter of $N_{D_{1}}\left(g G_{y}\right) \cap g^{\prime} G_{y^{\prime}}$ is infinite in $\Gamma$.

The rest of the argument is borrowed from [Mit04, Theorem 4.6]. Let $\left\{h_{n}\right\} \subset g G_{y}$ and $\left\{h_{n}^{\prime}\right\} \subset g^{\prime} G_{y^{\prime}}$ be sequences of distinct elements such that $d_{\Gamma}\left(h_{n}, h_{n}^{\prime}\right) \leq D_{1}$ for all $n \in \mathbb{N}$. Hence, $d_{\Gamma}\left(1, h_{n}^{-1} h_{n}^{\prime}\right) \leq D_{1}$. But there are only finitely many elements of $G$ inside $B\left(1 ; D_{1}\right)$. Hence, passing to a subsequence, we may assume that the sequence $\left\{h_{n}^{-1} h_{n}^{\prime}\right\}$ is constant. Let $x=h_{n}^{-1} h_{n}^{\prime}$. Consider the equations $x=h_{m}^{-1} h_{m}^{\prime}=h_{n}^{-1} h_{n}^{\prime}$; whence $h_{m} x=h_{m}^{\prime}, h_{n} x=h_{n}^{\prime}$. Thus, we have

$$
\begin{gathered}
x^{-1} h_{m}^{-1} h_{n} x=h_{m}^{\prime-1} h_{n}^{\prime} \Rightarrow h_{m}^{-1} h_{n}=x h_{m}^{\prime-1} h_{n}^{\prime} x^{-1} \\
\Rightarrow h_{m}\left(h_{m}^{-1} h_{n}\right) h_{m}^{-1}=\left(h_{m} x\right) h_{m}^{\prime-1} h_{n}^{\prime}\left(h_{m} x\right)^{-1}=h_{m}^{\prime}\left(h_{m}^{\prime-1} h_{n}^{\prime}\right) h_{m}^{\prime-1}
\end{gathered}
$$

Clearly, $h_{m}^{-1} h_{n} \in G_{y}$ and, hence, $h_{m}\left(h_{m}^{-1} h_{n}\right) h_{m}^{-1} \in h_{m} G_{y} h_{m}^{-1}=g G_{y} g^{-1}$, since $h_{m} \in g G_{y}$. Similarly, $h_{m}^{\prime}\left(h_{m}^{\prime-1} h_{n}^{\prime}\right) h_{m}^{-1} \in g^{\prime} G_{y^{\prime}} g^{\prime-1}$. This implies that

$$
h_{m}\left(h_{m}^{-1} h_{n}\right) h_{m}^{-1}=h_{m}^{\prime}\left(h_{m}^{\prime-1} h_{n}^{\prime}\right) h_{m}^{\prime-1} \in g G_{y} g^{-1} \cap g^{\prime} G_{y^{\prime}} g^{\prime-1}
$$

However, $g G_{y} g^{-1}$ is the stabilizer of the vertex $v=g G_{y}$ and $g^{\prime} G_{y^{\prime}} g^{\prime-1}$ is the stabilizer of $w=g^{\prime} G_{y^{\prime}}$. Since $\left\{h_{n}\right\}$ and $\left\{h_{n}^{\prime}\right\}$ are sequences of distinct elements in $g G_{y}$ and $g^{\prime} G_{y^{\prime}}$ respectively, the intersection $G_{v} \cap G_{w}$ is infinite. Since $d_{T}(v, w)=R+1$ this contradicts the $R$-acylindricity of the $G$-action.

Remark 2.52. 1. The proof of Proposition 2.51 also works even if we assume that $G_{v} \cap G_{w}$ finite whenever $d_{T}(v, w) \geq k+1$.
2. In fact, to conclude hyperbolicity of $G$ in the proposition, one does not need the full power of the Combination Theorem, Theorem 2.58, one can derive the result from the cobounded quasiconvex chain-amalgamation, Theorem 2.59.

For the next corollary, we recall that a subgroup $H$ in a group $G$ is weakly malnormal if for every $g \in G \backslash H$ the intersection

$$
g H g^{-1} \cap H
$$

is finite.
Corollary 2.53. ([KM98, Theorem 2]) If $G_{1}, G_{2}$ are hyperbolic groups and $H$ is a common quasiconvex subgroup which is weakly malnormal in either in $G_{1}$ or in $G_{2}$, then $G=G_{1} *_{H} G_{2}$ is hyperbolic.

Proof. We claim that the action of $G$ on the Bass-Serre tree for the given amalgam decomposition is 3-acylindrical. Without loss of generality let us assume that $H<G_{1}$ is weakly malnormal. If $T$ is the Bass-Serre tree and $v, w \in V(T)$ with $d_{T}(v, w) \geq 4$, then there are is a sequence of consecutive vertices on $v w$ of the form $v_{1}=x G_{2}, v_{2}=y G_{1}, v_{3}=$ $z G_{2}$, where $x, y, z \in G$. Then $G_{v_{1}} \cap G_{v_{3}}$ is equal to the intersection of the stabilizers of the two edges:
(i) one edge connecting $v_{1}, v_{2}$, and
(ii) the one edge connecting $v_{2}, v_{3}$.

However, these are two distinct conjugates of $H$ in the stabilizer of $v_{2}=y G_{1}$, i.e. they are of the form $y g{H g^{-1}}^{1}, y g^{\prime} H g^{\prime-1} y^{-1}$ in $y G_{1} y^{-1}$ where $g, g^{\prime} \in G_{1}$. Since

$$
y g H g^{-1} y^{1} \cap y g^{\prime} H g^{\prime-1} y^{-1}=y\left(g H g^{-1} \cap g^{\prime} H g^{\prime-1}\right) y^{-1}
$$

(weak) malnormality of $H$ in $G_{1}$ proves our claim. Then the hyperbolicity follows from Proposition 2.51.

An example analogous to the situation of the corollary above in the context of a tree of spaces is discussed in Section 2.6.2.

### 2.5.4. Exponential flaring (Bestvina-Feighn flaring condition).

Definition 2.54 (Exponential flaring condition). We say that a tree $\mathfrak{X}$ of metric spaces $\pi: X \rightarrow T$ it satisfies the Bestvina-Feighn $\kappa$-flaring condition or the exponential $\kappa$-flaring condition, if there exist $\lambda_{\kappa}>1, M_{\kappa}>0$ and $n_{\kappa} \in \mathbb{N}$ such that the following holds:

For every pair $\Pi=\left(\gamma_{0}, \gamma_{1}\right)$ of $\kappa$-qi sections of $\mathfrak{X}$ over a length $2 n_{\kappa}$ geodesic interval $\llbracket-n_{\kappa}, n_{\kappa} \rrbracket \subset T$, if the girth $\Pi_{0}$ of the pair $\left(\gamma_{0}, \gamma_{1}\right)$ is $\geq M_{\kappa}$, then

$$
\lambda_{\kappa} \cdot \Pi_{0} \leq \Pi_{\max } .
$$

A form of this flaring condition first appeared in the paper [BF92] of Bestvina and Feighn. Actually, the original Bestvina-Feighn flaring condition was a bit different from the exponential flaring condition above as they required not just two qi sections but a 1 parameter family of $\kappa$-qi sections interpolating these two, i.e. a $\kappa$-hallway, see Definition 3.15. The existence of such a family (with a different but uniform qi constant $\kappa^{\prime}$ ) follows from [MS09]. It will be also proven in Lemma 3.17(b).

We will see below that the exponential flaring implies proper flaring with an exponential function $\phi_{\kappa}$ and that if $X$ is hyperbolic, then $\mathfrak{X}$ satisfies the exponential $\kappa$-flaring condition for all $\kappa \geq 1$. Note that while in their first paper [BF92] Bestvina and Feighn imposed the exponential flaring condition for all $\kappa \geq 1$, in the addendum [BF96] to their paper, the flaring condition was required only for some value of $\kappa$, cf. the statement of our main result, Theorem 2.58.

Lemma 2.55. Bestvina-Feighn $\kappa$-flaring implies exponential proper $\kappa$-flaring. Moreover, the proper flaring condition holds either in the negative or in the positive direction (see Definition 2.42).

Proof. We fix $\kappa$ and set $n:=n_{\kappa}, \lambda:=\lambda_{\kappa}$. Suppose that $\Pi=\left(\gamma_{0}, \gamma_{1}\right)$ is a pair of $\kappa$-qi sections over a geodesic interval $I$ of length $N=s n$ and of girth $\Pi_{0} \geq m_{\kappa}$. For concreteness, we assume that

$$
d_{X_{n}}\left(\gamma_{0}(n), \gamma_{1}(n)\right) \geq \lambda d_{X_{0}}\left(\gamma_{0}(0), \gamma_{1}(0)\right)=\Pi_{0} .
$$

Then, applying the flaring inequality to the subinterval in $I$ of length $2 n$ centered at $n$, we obtain

$$
\max \left(d_{X_{2 n}}\left(\gamma_{0}(2 n), \gamma_{1}(2 n)\right), \Pi_{0}\right) \geq \lambda d_{X_{n}}\left(\gamma_{0}(n), \gamma_{1}(n)\right)
$$

Since $\lambda>1$, the maximum in this inequality is attained by $d_{X_{2 n}}\left(\gamma_{0}(2 n), \gamma_{1}(2 n)\right)$ and, thus,

$$
d_{X_{2 n}}\left(\gamma_{0}(2 n), \gamma_{1}(2 n)\right) \geq \lambda d_{X_{n}}\left(\gamma_{0}(n), \gamma_{1}(n)\right) .
$$

Applying this argument inductively, we obtain:

$$
\lambda_{\kappa}^{s} \cdot \Pi_{0} \leq d_{X_{s n}}\left(\gamma_{0}(s n), \gamma_{1}(s n)\right) \leq \Pi_{\max }(s n) .
$$

By reducing $\lambda$ to $\mu>1$ if necessary and using Lemma 2.37, we also get

$$
\Pi_{\max }(m) \geq d_{X_{m}}\left(\gamma_{0}(m), \gamma_{1}(m)\right) \geq \mu^{m} \Pi_{0}, \forall m \geq n
$$

Since the function $m \mapsto \mu^{m}, m \in \mathbb{N}$, is proper, the exponential proper $\kappa$-flaring condition for $\mathfrak{X}$ follows.

Proposition 2.56. If $\mathfrak{X}$ satisfies the proper $\kappa$-flaring condition for all $\kappa \geq 1$, then $\mathfrak{X}$ also satisfies satisfies an exponential $\kappa$-flaring condition for all $\kappa \geq 1$. In particular, if $X$ is hyperbolic, then $\mathfrak{X}$ satisfies satisfies an exponential $\kappa$-flaring condition for all $\kappa \geq 1$.

Proof. Since $X$ is hyperbolic, the tree of spaces $\mathfrak{X}=(X \rightarrow T)$ satisfies both the proper $\kappa$-flaring and the property obtained in Corollary 2.49 for all $\kappa \geq 1$. We will use both of these in the proof. The proof is inspired by, but is conceptually simpler than [MS09, Proposition 5.8]. For each $K \geq 1$, we inductively define $K_{0}:=K$ and $K_{i}:=\max \left\{K_{i-1}, C_{2.36}\left(K_{i-1}\right)\right\}$, $i \geq 1$. Given $\kappa \geq 1$ we set

$$
L:=\eta_{2.17}\left(2 \kappa_{3}\right), \epsilon=3 \eta_{2.17}\left(2 \kappa_{3}\right), \quad R:=\max \left\{1, m_{\kappa_{3}}, L(5 \epsilon+4 L)\right\}
$$

and $D:=\max \left\{R, R_{2.49}\left(\kappa_{3}, R\right)\right\}$. Let $n=n_{\kappa}$ be any integer such that $\phi_{\kappa_{3}}(n) \geq 12 D$; set $\lambda_{\kappa}:=2$ and $M_{\kappa}:=D+1$.

If $\Pi=\left(\gamma_{0}, \gamma_{1}\right)$ is a pair of $\kappa$-qi sections over an interval $J=[-n, n] \subset T, \Pi_{0} \geq M_{\kappa}$, then we form a metric bundle $\mathfrak{Y}=(Y \rightarrow J)$ :

The vertex-spaces $Y_{i}$ of $Y$ are geodesic segments in $X_{i}$ joining $\gamma_{0}(i), \gamma_{1}(i)$. The edgespaces $Y_{e}, e=[i, i+1]$, of $\mathfrak{V}$ ) are geodesic segments in $X_{e}$ with end-points within distance $\kappa$ from the respective end-points of $Y_{i}$. The incidence maps of $\mathfrak{Y}$ are obtained by composing the incidence maps of $f_{e v}, v \in V(J)$, composed with the nearest-point projections to $Y_{v}$ (taken in $X_{v}$ ).

After that, the idea is to first decompose this interval-bundle into a finite number of subbundles by constructing qi sections in $Y$ (cf. [MS09, Proposition 3.14], also Proposition 4.11), where the subbundles intersect along the qi sections. We then use proper flaring to prove that the qi sections bounding each of the subbundles flare in at least one direction. Finally, as in the last step of the proof of [MS09, Proposition 5.8], we verify that at least half of these will flare in the same direction to finish the proof.

Step 1: Construction of qi sections in $Y$. We note that through any point of the metric bundle formed by two $K_{i-1}$-qi sections, there is a $K_{i}$-qi section, $i \geq 1$. Let $\alpha_{i}=Y \cap X_{i}$, $i \in V(J)$. For two consecutive integers $i, j$ we have a map $h_{i j}: \alpha_{i} \rightarrow \alpha_{j}$ such that for all $x \in \alpha_{i}, d_{X_{i j}}\left(h_{i j}(x), x\right) \leq \kappa_{3}$. This map is clearly $\eta_{2.17}\left(2 \kappa_{3}\right)$-coarsely Lipschitz, with a similarly defined $\eta_{2.17}\left(2 \kappa_{3}\right)$-coarse inverse $h_{j i}: \alpha_{j} \rightarrow \alpha_{i}$, which is also an $\eta_{2.17}\left(2 \kappa_{3}\right)$-coarsely Lipschitz map. Hence, by Lemma 1.14, the maps $h_{i j}, h_{j i}$ are both $\left(\eta_{2.17}\left(2 \kappa_{3}\right), 3 \eta_{2.17}\left(2 \kappa_{3}\right)\right)$ quasiisometries. By Lemma 1.23, if $x, y, z \in \alpha_{i}$ and $y$ is between $x, z$ with $d_{X_{i}}(x, y) \geq$ $L(5 \epsilon+4 L)$, and $d_{X_{i}}(y, z) \geq L(5 \epsilon+4 L)$, then $h_{i j}(y)$ is between $h_{i j}(x)$ and $h_{i j}(z)$. In particular, this is true if $d_{X_{i}}(x, y) \geq R$ and $d_{X_{i}}(y, z) \geq R$ by the choice of $R$.

Suppose $l\left(\alpha_{0}\right)=l$ and let $\alpha_{0}$ also denote the parametrization of this geodesic in $X_{0}$ so that $\alpha_{0}(0)=\gamma_{0}(0), \alpha_{0}(l)=\gamma_{1}(0)$. Next, we inductively construct a sequence of numbers $s_{0}=0, \cdots, s_{n}=l$ and a sequence of $\kappa_{1}$-qi sections $\gamma_{0}=\beta_{0}, \beta_{1}, \cdots, \beta_{n}=\gamma_{1}$ in $Y$ such that each $\beta_{i+1}$ is contained in the metric bundle formed by $\beta_{i}$ and $\beta_{n}, 0 \leq i \leq n-2$ as follows. Suppose $s_{0}, \cdots, s_{i}$ are chosen and so are $\beta_{0}, \cdots, \beta_{i}$ and $s_{i}<l$. To construct $s_{i+1}$ and $\beta_{i+1}$ consider the subset $S \subset\left(s_{i}, l\right]$ consisting of $s$ such that there is a $\kappa_{2}$-qi section $\beta$ through $s$ satisfying

$$
\min _{j} d_{X_{j}}\left(\beta(j), \beta_{i}(j)\right) \leq R
$$

If $S=\emptyset$ then define $s_{i+1}=s_{n}=\gamma_{1}$. Assume now that $S$ is nonempty. Suppose there is $s \in S$ and a $\kappa_{1}$-qi section $\beta$ in $Y$ through $\alpha_{0}(s)$ such that $\min _{j} d_{X_{j}}\left(\beta(j), \beta_{i}(j)\right)=R$. In this case, if $s \neq l$, then define $s_{i+1}=s, \beta_{i+1}=\beta$. Otherwise, if $s=l$, then we define $s_{i+1}=s_{n}=l$ and $\beta_{n}=\gamma_{1}$. Suppose there is no such $s \in S$. Then let $s_{i+1}=\min \{l, 1+\sup S\}$. If $s_{i+1} \neq l$, then let $\beta_{i+1}$ be any $\kappa_{1}$-qi section in $Y$ passing through $s_{i+1}$. Otherwise, define $s_{n}=s_{i+1}$ and $\beta_{i+1}=\gamma_{1}$. We note that $s_{i+1}-s_{i} \geq R$ unless $s_{i+1}=s_{n}$.

Step 2: Verification of the properties of the qi sections. Let $\Pi^{i}=\left(\beta_{i}, \beta_{i+1}\right)$ and let $Y^{i}$ denote the interval-bundle over $J$ formed by these qi sections. We claim that $Y^{i} \cap Y^{j}=\emptyset$, unless $|i-j| \leq 1$, and $Y^{i} \cap Y^{i+1}=\beta_{i+1}$ for all permissible $i$. Both claims follow from Lemma 1.23, cf. Lemma 3.12 of [MS09].

Step 3: Flaring of $\Pi^{i}=\left(\beta_{i}, \beta_{i+1}\right)$. We know that there is a $\kappa_{2}$-qi section $\bar{\beta}_{i}$ through either $s_{i+1}$ or $s_{i+1}-1$ inside the subbundle $Y^{i}$, such that

$$
d_{X_{j}}\left(\beta_{i}\left(u_{i}\right), \bar{\beta}_{i}\left(u_{i}\right)\right) \leq R
$$

for some $u_{i} \in V(J)$. Without loss of generality, we may assume that $u_{i}<0$. Now we construct a new set of $\kappa_{3}$-qi sections inside the bundle formed by $\beta_{i}$ and $\bar{\beta}_{i}$ as follows. Let $r=\left\lfloor\left(s_{i+1}-s_{i}-1\right) / D\right\rfloor$. Let $\beta_{j}^{\prime}, 0 \leq j \leq r$ be arbitrary $\kappa_{3}$-qi sections in the bundle formed by $\beta_{i}, \bar{\beta}_{i}$ such that $\beta_{0}^{\prime}=\beta_{i}$, and for $j \neq 0 \beta_{j}^{\prime}$ passes through $\alpha_{0}\left(s_{i}+j D\right)$. It follows from Lemma 2.49 that for all $j, k \geq 0 d_{X_{j}}\left(\beta_{k}^{\prime}(j), \beta_{k+1}^{\prime}(j)\right) \geq R$ and, thus, as in step 2, by Lemma 1.23 we see that

$$
\beta_{i}(j)=\beta_{0}^{\prime}(j), \cdots, \beta_{m}^{\prime}(0), \beta_{i+1}(j)
$$

is a monotonic sequence in the geodesic interval $\left[\beta_{i}(j) \beta_{i+1}(j)\right]_{X_{j}}$ for all $j \geq 0$. Thus,

$$
\begin{array}{r}
d_{X_{n}}\left(\beta_{i}(n), \beta_{i+1}(n)\right) \geq \sum_{j=0}^{r-1} d_{X_{n}}\left(\beta_{j}^{\prime}(n), \beta_{j+1}^{\prime}(n)\right) \geq \\
\sum_{j=0}^{r-1} 12 D=\sum_{j=0}^{r-1} 12 d_{X_{0}}\left(\beta_{j}^{\prime}(0), \beta_{j+1}^{\prime}(0)\right)=12 d_{X_{0}}\left(\beta_{0}^{\prime}(0), \beta_{r}^{\prime}(0)\right)
\end{array}
$$

by the proper flaring and by the choice of $n$. However,

$$
d_{X_{0}}\left(\beta_{i}(0), \beta_{i+1}(0)\right)=d_{X_{0}}\left(\beta_{0}^{\prime}(0), \beta_{r}^{\prime}(0)\right)+d_{X_{0}}\left(\beta_{r}^{\prime}(0), \beta_{i+1}(0)\right)
$$

where $d_{X_{0}}\left(\beta_{r}^{\prime}(0), \beta_{i+1}(0) \leq D+1\right.$. It follows that

$$
d_{X_{n}}\left(\beta_{i}(n), \beta_{i+1}(n)\right) \geq \frac{12 D}{2 D+1} d_{X_{0}}\left(\beta_{i}(0), \beta_{i+1}(0)\right) \geq 4 d_{X_{0}}\left(\beta_{i}(0), \beta_{i+1}(0)\right)
$$

since $D \geq 1$.
Step 4: Exponential flaring of $\gamma_{0}, \gamma_{1}$. We know that each pair $\Pi^{i}=\left(\beta_{i}, \beta_{i+1}\right)$ exponentially flares in at least one direction (say, in the positive direction) by Step 3. Then there is a subset of induces $I \subset\{1,2, \ldots\}$, such that

$$
\sum_{i \in \mathcal{I}} \Pi_{0}^{i} \geq \frac{1}{2} \Pi_{0}
$$

It follows that $\Pi$ flares exponentially in the positive direction with $\lambda_{\kappa}=2$.
Corollary 2.57. If $\mathfrak{X}$ satisfies the proper $\kappa$-flaring condition for all $\kappa \geq 1$, then (again, for all $\kappa \geq 1$ ) it satisfies proper flaring either in positive or in the negative direction.

### 2.6. Hyperbolicity of trees of hyperbolic spaces

2.6.1. The combination theorem. We are now ready to state our version of the combination theorem of Bestvina and Feighn [BF92]:

Theorem 2.58. There exist $K_{*}=K_{2.58}\left(\delta_{0}, L_{0}\right)$ and $\delta_{*}=\delta_{2.58}\left(\delta_{0}, L_{0}\right)$, depending only on $\delta_{0}$ and $L_{0}$, such that the following holds. Suppose $\mathfrak{X}=(\pi: X \rightarrow T)$ is a tree of hyperbolic spaces (with primary parameters $\delta_{0}, L_{0}$ ) satisfying the uniform $K_{*}$-flaring condition. Then $X$ is a $\delta_{*}$-hyperbolic metric space.

The constants $K_{*}$ and $\delta_{*}$ are computable. In Remark 6.12 we will give a formula for $K_{*}$, which is inductive in nature, as it relies upon earlier computations of various constants and functions scattered throughout the book. (We will not attempt to write a formula for $\delta_{*}$.) The reader unwilling to keep track of such computations, can simply assume that $\mathfrak{X}$ satisfies the uniform $\kappa$-flaring condition for all $\kappa \geq 1$.
2.6.2. Cobounded quasiconvex chain-amalgamation. In the book we will be frequently using the following very special case of Theorem 2.58 which is much easier to prove, see e.g. [MS09, Proposition 1.51]. This special case was motivated by a result of Hamenstadt, [Ham05, Lemma 3.5]. Although Hamenstadt used much stronger assumptions, it is clear that the proof of Hamenstadt goes through with the weaker hypothesis as well. We include a proof along the lines of Hamenstadt's arguments for the sake of completeness and also since we want a description of geodesics.

We assume that $X$ is a path-metric space that can be represented as a union of a finite chain of rectifiably-connected subsets equipped with induced path-metrics

$$
Y=Q_{0} \cup Q_{1} \cup \ldots \cup Q_{n},
$$

such that for some constants $C$ and $\delta$ the following hold:
(1) Each $Q_{i}$ is $\delta$-hyperbolic.
(2) For each $i<n$ the intersection $Q_{i, i+1}=Q_{i} \cap Q_{i+1}$ is rectifiably connected and $L$-qi embedded in $Q_{i}, Q_{i+1}$.
(3) Each $Q_{i, i+1}$ separates (in $Y$ ) $Q_{i}$ from $Q_{i+1}$ in the sense that every path $c$ in $X$ connecting $Q_{i}$ to $Q_{i+1}$ has to cross $Q_{i, i+1}$.
(4) Each pair of intersections $Q_{i-1, i}, Q_{i, i+1}$ is $C$-cobounded in $Q_{i}$.
(5) $d_{Q_{i}}\left(Q_{i-1, i}, Q_{i, i+1}\right) \geq 1$.

We will say that such $X$ is a cobounded quasiconvex chain-amalgam of $Q_{i}$ 's. If $n=1$, we will refer to $X=Q_{0} \cup Q_{1}$ simply as a quasiconvex amalgam.

Clearly, the collection $Q_{i}$ 's in a cobounded quasiconvex chain-amalgam gives $X$ structure of a tree of hyperbolic spaces with vertex-spaces $Q_{i}$ and edge-spaces $Q_{i, i+1}$, such that the tree $T$ is isometric to the interval $J$ of length $n+1$ in $\mathbb{R}$ with integer vertices. Conversely, consider a tree of hyperbolic spaces $\mathfrak{X}$ over an interval $T$ such that for each vertex $v$ with the incident edges $e_{ \pm}$, the corresponding subsets $X_{e_{ \pm} v}$ are $C^{\prime}$-cobounded in $X_{v}$. Then $\mathfrak{X}$ yields a cobounded quasiconvex chain-amalgam with subsets $Q_{i}=Q_{v}, v=v_{i}$, equal to the unions

$$
\begin{gathered}
X_{e_{-}} \times\left[\frac{1}{2}, 1\right] \cup_{f_{e_{-}}} X_{v} \cup_{f_{e_{+} v}} X_{e_{+}} \times\left[0, \frac{1}{2}\right], \\
Q_{i-1, i}=X_{e_{-}} \times \frac{1}{2}
\end{gathered}
$$

see Section 1.6 for the definition of mapping cylinders.
For each $i$ pick points

$$
x_{i}^{-} \in N_{C^{\prime}}\left(P_{Q_{i}, Q_{i-1, i}}\left(Q_{i, i+1}\right)\right) \cap Q_{i-1, i}, x_{i}^{+} \in N_{C^{\prime}}\left(P_{Q_{i}, Q_{i, i+1}}\left(Q_{i-1, i}\right)\right) \cap Q_{i, i+1},
$$

where the $C^{\prime}$-neighborhoods are taken with respect to the metric of $Q_{i}, Q_{i}$. Since both projections of $Q_{i-1, i}$ to $Q_{i, i+1}$ and of $Q_{i, i+1}$ to $Q_{i-1, i}$ have diameters $\leq C$, we obtain

$$
\begin{equation*}
d_{Q_{i}}\left(Q_{i-1, i}, Q_{i, i+1}\right) \leq d_{Q_{i}}\left(x_{i}^{-}, x_{i}^{+}\right) \leq d_{Q_{i}}\left(Q_{i-1, i}, Q_{i, i+1}\right)+2\left(C+C^{\prime}\right), \tag{2.1}
\end{equation*}
$$

i.e. the pair of points $x_{i}^{-}, x_{i}^{+}$"almost" realizes the minimal distance in $Q_{i}$ between the subsets $Q_{i-1, i}, Q_{i, i+1}$.

We will simultaneously prove hyperbolicity of $X$ and describe uniform quasigeodesics connecting points in $X$. For this description, given points $x \in Q_{i-1}, x^{\prime} \in Q_{k+1}$, it will be convenient to name their nearest-point projections (in $Q_{i-1}, Q_{k+1}$ ) to $Q_{i-1, i}, Q_{k, k+1}$ as $\bar{x}, \bar{x}^{\prime}$, respectively. Suppose, furthermore, that

$$
c\left(x_{i}^{+}, x_{i+1}^{-}\right)
$$

are $L^{\prime}$-quasigeodesic paths in $Q_{i, i+1}$ connecting $x_{i}^{+}$to $x_{i+1}^{-}$and

$$
c\left(x_{i}^{-}, x_{i}^{+}\right), c(x, \bar{x}), c\left(\bar{x}^{\prime}, x^{\prime}\right)
$$

are $L^{\prime}$-quasigeodesic paths in $Q_{i}$ connecting $x_{i}^{-}$to $x_{i}^{+}$, etc. We let $c^{*}(\cdot, \cdot)$ denote the corresponding geodesics paths in $Q_{i, i+1}, Q_{i}$, connecting the respective points.

Theorem 2.59. Under the above assumptions, $X$ is $\delta_{2.59}\left(\delta, L, L^{\prime}, C, C^{\prime}\right)$-hyperbolic. Moreover, the following paths $c\left(x, x^{\prime}\right)$ are $K=K_{2.59}\left(\delta, L, C, D, L^{\prime}\right)$-quasigeodesics in $X$ connecting $x \in Q_{i-1}, x^{\prime} \in Q_{k+1}, i \leq k$ :

1. If $x, x^{\prime}$ belong to $Q_{i}^{\prime}=Q_{i} \backslash\left(Q_{i-1, i} \cup Q_{i, i+1}\right)$ for some $i$, then we assume that $c\left(x, x^{\prime}\right)$ is an $L^{\prime}$-quasigeodesic in $Q_{i}$ connecting $x$ to $x^{\prime}$.
2. Otherwise,

$$
c\left(x, x^{\prime}\right)=c(x, \bar{x}) \star c\left(\bar{x}, x_{i}^{-}\right) \star c\left(x_{i}^{-}, x_{i}^{+}\right) \star c\left(x_{i}^{+}, x_{i+1}^{-}\right) \star \ldots \star c\left(x_{k}^{+}, \bar{x}^{\prime}\right) \star c\left(\bar{x}^{\prime}, x^{\prime}\right)
$$

Proof. This theorem is proven by verifying the assumptions of Corollary 1.64, i.e. axioms of a slim combing.
(a1) We will need to estimate the length of $c\left(x, x^{\prime}\right)$ in terms of $d\left(x, x^{\prime}\right)$. First of all,

$$
\text { length }\left(c\left(x, x^{\prime}\right)\right) \leq L^{\prime}\left(\text { length }\left(c^{*}\left(x, x^{\prime}\right)\right)+1\right)
$$

hence, it suffices to get an estimate for $c^{*}$.
Let $\gamma$ be any geodesic in $X$ connecting $x$ to $x^{\prime}$. In view of the separation property (3) in the theorem, for each $i \leq j \leq k, \gamma$ will contain subpaths $\gamma_{j} \subset Q_{j}$ (necessarily a geodesic in $Q_{j}$ ) connecting a point $p_{j}^{-} \in Q_{j-1, j}$ to some $p_{j}^{+} \in Q_{j, j-1}$.

Let $P_{-}, P_{+}$denote the projections $Q_{j} \rightarrow Q_{j-1, j}, Q_{j} \rightarrow Q_{j, j+1}$ respectively. According to Lemma 1.102, $\gamma_{j}$ contains points $y_{j}^{ \pm}$satisfying

$$
d_{Q_{j}}\left(y_{j}^{ \pm}, P_{ \pm}\left(p_{j}^{\mp}\right)\right) \leq 2 \delta+\lambda
$$

hence,

$$
d_{Q_{j}}\left(y_{j}^{ \pm}, x_{j}^{ \pm}\right) \leq D:=C+C^{\prime}+2 \delta+\lambda,
$$

where $\lambda=\lambda_{1.90}(\delta, L)$ is the quasiconvexity constant of $Q_{j, j \pm 1}$ in $Q_{j}$. Thus,

$$
\text { length }\left(\left[p_{j}^{-} x_{j}^{-}\right]_{Q_{j}} \star\left[x_{j}^{-} x_{j}^{+}\right]_{Q_{j}} \star\left[x_{j}^{+} p_{j}^{+}\right]_{Q_{j}}\right) \leq \text { length }\left(\gamma_{j}\right)+4 D .
$$

Since $Q_{j-1, j}, Q_{j, j+1}$ are $L$-qi embedded in $Q_{j}$ we also obtain

$$
\begin{equation*}
\text { length }\left(c\left(p_{j}^{-}, p_{j}^{+}\right)\right) \leq L \cdot \operatorname{length}\left(\gamma_{j}\right)+4 D(L+1) \tag{2.2}
\end{equation*}
$$

Since

$$
\text { length }(\gamma) \geq d\left(x, p_{i}^{-}\right)+\sum_{j=i}^{k} \text { length }\left(\gamma_{j}\right)+d\left(p_{k}^{+}, x^{\prime}\right)
$$

by combining the inequalities (2.2), we get:

$$
\text { length }\left(c^{*}\left(x_{i}^{-}, x_{k}^{+}\right)\right) \leq \text {length }\left(c\left(p_{i}^{-}, p_{k}^{+}\right)\right) \leq L \sum_{j=i}^{k} \operatorname{length}\left(\gamma_{j}\right)+4 D(L+1)(k-i+1)
$$

To estimate the term $4 D(L+1) m, m=k-i+1$, note that $d(x, y) \geq m$ (in view of the assumption 5 in the theorem). Thus,

$$
\text { length }\left(c^{*}\left(x_{i}^{-}, x_{k}^{+}\right)\right) \leq L d\left(x, x^{\prime}\right)+4 D(L+1) d\left(x, x^{\prime}\right)=(L+4 D(L+1)) d\left(x, x^{\prime}\right)
$$

Lastly, we deal with $d\left(x, x_{i}^{-}\right)$and $d\left(x^{\prime}, x_{k}^{+}\right)$. Recall that the metric space $\left(Q_{i}, d_{Q_{i}}\right)$ is $\eta$-properly embedded in $X$ (Proposition 2.17). We obtain:

$$
\begin{array}{r}
\text { length } c^{*}\left(x, x_{i}^{-}\right)=d_{Q_{i}}(x, \bar{x})+d_{Q_{i-1, i}}\left(\bar{x}, x_{i}^{-}\right) \leq \\
d_{Q_{i-1}}(x, \bar{x})+L+L d_{Q_{i-1}}\left(\bar{x}, x_{i+1}^{-}\right) \leq L+2 D+L d_{Q_{i-1}}\left(x, x_{i}^{-}\right) \leq \\
L+2 D+L \eta\left(d\left(x, x_{i}^{-}\right)\right) \leq \\
L+2 D+L \eta\left(d\left(x, y_{i}^{-}\right)+D\right) \leq L+2 D+L \eta\left(d\left(x, x^{\prime}\right)+D\right) .
\end{array}
$$

Similarly,

$$
\text { length } c^{*}\left(x^{\prime}, x_{k}^{+}\right) \leq L+2 D+\operatorname{L\eta }\left(d\left(x, x^{\prime}\right)+D\right)
$$

Combining the inequalities, we obtain:

$$
\begin{aligned}
& \text { length }\left(c^{*}\left(x, x^{\prime}\right)\right)=\text { length } c^{*}\left(x, x_{i}^{-}\right)+\text {length }\left(c\left(x_{i}^{-}, x_{k}^{+}\right)+\text {length } c^{*}\left(x^{\prime}, x_{k}^{+}\right) \leq\right. \\
& \eta_{2.59}\left(d\left(x, x^{\prime}\right)\right):=2\left(L+2 D+\operatorname{L\eta }\left(d\left(x, x^{\prime}\right)+D\right)\right)+(L+4 D(L+1)) d\left(x, x^{\prime}\right)
\end{aligned}
$$

(a2) Consider a triple of points $x \in Q_{i}, y \in Q_{j}, z \in Q_{k}, i \leq j \leq k$, and the "triangle"

$$
\Delta_{c}=c(x, y) \cup c(y, z) \cup c(z, x)
$$

By the definition of the paths $c$ in $X$, the paths $c(x, y), c(y, z)$ coincide away from $Q_{j}$, the same applies to the pair of paths $c(y, z), c(z, x)$. Therefore, it suffices to consider the case when $i=j=k$.

We will use the notation $p q$ for geodesics in $Q_{i}$. Our goal is to verify that each of the paths $c(p, q)$ connecting points $p, q \in Q_{i}$ are uniformly Hausdorff-close to a geodesic $p q$ : Once we are done with this, then uniform slimness of $\Delta_{c}$ will follow from $\delta$-hyperbolicity of $Q_{i}$.

If both $p, q$ are in $Q_{i}^{\prime}$ or in $Q_{i, i+1}$ or in $Q_{i-1, i}$, there is nothing to prove. Hence, up to permutation of the points $p, q$ and reversing the order in the interval $[0, n]$, there are two cases to consider, depending on the position of the points $p, q$ with respect to the subsets $Q_{i-1, i}, Q_{i, i+1}$ :

Case 1. Suppose that $p \notin Q_{i-1, i}$ and $q \in Q_{i, i+1}$. We will be using the notation $\bar{p}=$ $P_{Q_{i}, Q_{i, i+1}}(p)$. Then

$$
c(p, q)=c(p, \bar{p}) \cup c(\bar{p}, p)
$$

Since $Q_{i, i+1}$ is $L$-qi embedded in $Q_{i}$, this path is $D_{1.53}\left(\delta, L L^{\prime}\right)$-Hausdorff close to the union $p \bar{p} \cup \bar{p} q$. According to Lemma 1.100,

$$
\operatorname{Hd}_{Q_{i}}(p \bar{p} \cup \bar{p} q, p q) \leq \lambda+2 \delta,
$$

concluding the proof in this case.
Case 2. Suppose that $p \in Q_{i-1, i}$ and $q \in Q_{i, i+1}$. In view of the assumption that $Q_{i-1, i}, Q_{i, i+1}$ are $L$-qi embedded in $Q_{i}$, we will work with $Q_{i}$-geodesics connecting pairs of points points in $Q_{i-1, i}$ and pairs of points in $Q_{i, i+1}$ instead of the $c$-paths in $Q_{i-1, i}$ and $Q_{i, i+1}$. Continuing with the notation of Case 1 ,

$$
\operatorname{Hd}_{Q_{i}}(p q, p \bar{p} \cup \bar{p} q) \leq \lambda+3 \delta
$$

(see Lemma 1.102) and

$$
d\left(\bar{p}, x_{i}^{+}\right) \leq C .
$$

Thus,

$$
\operatorname{Hd}_{Q_{i}}\left(p q, p x_{i}^{+} \cup x_{i}^{+} q\right) \leq C+\lambda+4 \delta .
$$

Similarly,

$$
\operatorname{Hd}_{Q_{i}}\left(p x_{i}^{+}, p x_{i}^{-} \cup x_{i}^{-} x_{i}^{+}\right) \leq C+\lambda+4 \delta .
$$

Combining the inequalities, we obtain

$$
\operatorname{Hd}_{Q_{i}}\left(p q, p x_{i}^{+} \cup x_{i}^{-} x_{i}^{+} \cup x_{i}^{+} q\right) \leq 2(C+\lambda+4 \delta) .
$$

Remark 2.60. The flexibility of working with concatenations of quasigeodesics points $x_{i}^{ \pm}$uniformly close to nearest-point projections will be critical in several places in the book, e.g. in Chapter 8.

Corollary 2.61. Assuming that $X \rightarrow T$ is a tree of hyperbolic spaces satisfying the assumptions of Theorem 2.59, for every subinterval $S \subset T$, the inclusion map

$$
X_{S} \rightarrow X
$$

is an $L_{2.61}(\delta, L, C)$-qi embedding.
Proof. This is an immediate consequence of the of the fact that for any pair of points $x, y^{\prime} \in S_{X}$, the path $c_{X_{S}}\left(x, x^{\prime}\right)$ equals the path $c_{X}\left(x, x^{\prime}\right)$ where the subscript denotes the space in which we define the combing.

Corollary 2.62. Suppose that $\mathfrak{X}=(\pi: X \rightarrow T)$ is a tree of spaces satisfying Axiom H. Then, for every edge $e=[v, w]$ of $T$ the space $X_{v w}$ equipped with its natural pathmetric, is $\delta_{0}^{\prime}$-hyperbolic with the hyperbolicity constant $\delta_{0}^{\prime}$ depending only on the primary parameters of the tree of hyperbolic spaces $\mathfrak{X}$.

We now return to the general quasiconvex chain-amalgamation and relate this class of trees of spaces to acylindrical trees of spaces. Suppose that $\gamma$ is a $\kappa$-qi section of the tree of spaces $\mathfrak{X}=(\pi: X \rightarrow J)$, defined on an interval $I \subset J$. Thus, for each integer $i$ we have a point $x_{i} \in Q_{i}$ and $d_{Y}\left(x_{i}, x_{i+1}\right) \leq K$ for some $K$ depending on $\kappa$. If the length of $I$ is $\geq 3$, it follows that for each triple of indices $i-1, i, i+1$ the point $x_{i}$ is within uniform distance $D=D(K)$ from both $Q_{i-1, i}$ and $Q_{i, i+1}$ : There exist $y_{i}^{-} \in Q_{i-1, i}, y_{i}^{+} \in Q_{i, i+1}$ such that

$$
d\left(x_{i}, y_{i}^{ \pm}\right) \leq K
$$

Such a point $x_{i}$ might not even exist, which would mean that each $\kappa$-qi section $\gamma$ of $\mathfrak{X}$ is defined only on an interval of length $\leq 2$, and that would definitely ensure acylindricity of $\mathfrak{X}$. In general, one can say that

$$
d\left(P_{Q_{i}, Q_{i-1, i}}\left(y_{i}^{+}\right), x_{i}^{-}\right) \leq 2 K, \quad d\left(P_{Q_{i}, Q_{i, i+1}}\left(y_{i}^{-}\right), x_{i}^{+}\right) \leq 2 K,
$$

and, hence,

$$
d\left(x_{i}, x_{i}^{ \pm}\right) \leq 3 K .
$$

It follows that any two $\kappa$-qi sections $\gamma_{0}, \gamma_{1}$ defined on $I$ satisfy

$$
d\left(\gamma_{0}(i), \gamma_{1}(i)\right) \leq 6 K, i \in V(I)
$$

thereby ensuring $(6 K, \kappa, 3)$-acylindricity of $\mathfrak{X}$.
2.6.3. Hyperbolicity of finite trees of hyperbolic spaces. We will also need the following version of Theorem 2.59 in the situation when the coboundedness condition is dropped:

Corollary 2.63. Suppose that $T$ is a finite tree, $\mathfrak{X}=(\pi: X \rightarrow T)$ is a tree of hyperbolic spaces (satisfying Axiom $\mathbf{H}$ ). Then $X$ is $\delta$-hyperbolic with

$$
\delta=\delta_{2.63}\left(\delta_{0}, L_{0},|V(T)|\right),
$$

i.e. $\delta$ depends only on the parameters of $\mathfrak{X}$ and the cardinality of $|V(T)|$.

Proof. The proof is induction on $|V(T)|$. For $|V(T)|=1$, there is nothing to prove. For $n=2$, the corollary is nothing but Theorem 2.59 for the quasiconvex amalgam of pairs. We, thus, assume that the corollary holds for all trees $S$ with $|V(S)|=n \geq 2$. Let $\mathfrak{X}=(\pi: X \rightarrow T)$ be a tree of hyperbolic spaces with $|V(T)|=n+1$. Pick a valence 1 vertex $w$ of $T$ and let $e=[v, w]$ be the incidence edge. Set $Y_{v}:=X_{v w}$. We then form a new tree of spaces $\mathfrak{Y}=(Y \rightarrow S)$, where $S$ is obtained from $T$ by removing $w$ and $e$, hence, $S$ has one less vertex than $T$. For vertices of $S$ which are distinct from $v$ and edges which are not incident to $v$, we use the same incidence maps for $\mathfrak{Y}$ as we had for $\mathfrak{X}$. For edges $e_{i}=\left[v_{i}, v\right]$ incident to $v$ we use incidence maps $Y_{e_{i}}=X_{e_{i}} \rightarrow Y_{v}=X_{v w}$ equal to the corestrictions of the incidence maps $X_{e_{i}} \rightarrow X_{v}$. The new tree of spaces still satisfies the assumptions of the corollary since $Y_{v}=X_{v w}$ is $\delta_{1}=\delta\left(\delta_{0}, L_{0}, 2\right)$-hyperbolic and incidence maps

$$
f_{e_{i} v}: X_{e_{i}} \rightarrow Y_{v}=X_{v w}
$$

are $L_{1}=L_{0} \cdot L_{0}^{\prime}$-qi embeddings, where $L_{0}^{\prime}=L_{2.27}\left(\delta, L_{0}\right)$. Now, $\delta=\delta\left(\delta_{0}, L_{0}, n\right)$-hyperbolicity of $X$ follows from the induction hypothesis.
2.6.4. Secondary parameters of trees of hyperbolic spaces. In addition to the primary parameters of trees of hyperbolic spaces $\mathfrak{X}=(X \rightarrow T)$, we will be frequently using secondary parameters, which are functions of the primary parameters. Since these secondary parameters are used so often, we will give them special names. First of all, we recall some constants defined earlier, namely, $\lambda_{0}$, the quasiconvexity constant of the images $X_{e v}$ of incidence maps $X_{e} \rightarrow X_{v}$ and $L_{0}^{\prime} \geq 2$, the quasiisometry constant for the inclusion maps $X_{v} \rightarrow X_{v w}$, where $e=[v, w]$ runs over all edges of $T$ (Lemma 2.27). Also, $\delta_{0}^{\prime}$ is the supremum of hyperbolicity constants of the spaces $X_{u v}=X_{\llbracket u, v \rrbracket}$ (Corollary 2.62). Let $\lambda_{0}^{\prime}$ denote an upper bound on the quasiconvexity constants for the images in $X_{v w}$ of $4 \delta_{0}$-quasiconvex subsets in $X_{v}, X_{e}$ (in particular, each $X_{v}, X_{e}$ is $\lambda_{0}^{\prime}$-quasiconvex in $X_{v w}$ ). Explicitly, one can take

$$
\lambda_{0}^{\prime}=92\left(L_{0}^{\prime}\right)^{2}\left(L_{0}^{\prime}+3 \delta_{0}^{\prime}\right)
$$

We will also use the notation $L_{1}^{\prime}$ for an upper bound of coarse Lipschitz constants of projections $P=P_{X_{u v}, X_{v}}: X_{u v} \rightarrow X_{v}, L_{1}^{\prime}=\left(L_{0}^{\prime}+1\right) \cdot D_{1.99}\left(\delta_{0}^{\prime}, \lambda_{0}^{\prime}\right)$ (Lemma 1.99). Last, but not least, we define the constant

$$
\begin{equation*}
K_{0}:=\left(15\left(2 \lambda_{0}^{\prime}+5 \delta_{0}^{\prime}\right) L_{0}^{\prime}\right)^{3} \tag{2.3}
\end{equation*}
$$

The importance of this constant will become clear in Chapter 3 during the discussion of flows of quasiconvex subsets of vertex-spaces of $\mathfrak{X}$. This constant will be critical in computing the flaring constant $K_{*}$ in Theorem 2.58.

### 2.7. Flaring for semidirect products of groups

The purpose of this section is to illustrate the concept of flaring in the case of semidirect products of groups, $G=H \rtimes \mathbb{Z}$.

Suppose $H$ is a nonelementary finitely generated group (which we will eventually assume to be hyperbolic) with a finite generating set $S$ and the corresponding word-metric $d_{H}$. Recall that the word-length of an element $h \in H$, denoted $|h|_{H}$ or $|h|_{S}$, when the generating set is to be stressed, is related to $d_{H}$ by $|h|_{H}=d_{H}(1, h)$.

Let $f: H \rightarrow H$ be an automorphism and $G=H \rtimes_{f}\langle t\rangle$ the corresponding semidirect product. Let $S_{G}=S \cup\{t\}$ be a generating set of $G$, where $t$ is the stable letter corresponding to the infinite cyclic factor in the semidirect product. Let $X$ be the Cayley graph $\Gamma(G, S)$; define the linear tree $T=\Gamma(\mathbb{Z}, 1)$. Then we have a tree of metric spaces $\pi: X \rightarrow T$, where the vertex spaces are various left cosets $X_{i}:=t^{i} H, i \in \mathbb{Z}$, of $H$ in $G$. (Strictly speaking, $X$ is only quasiisometric to the 2-dimensional complex which is the total space of the abstract tree of spaces whose vertex spaces are isometric copies of the Cayley graph of H.) We shall denote the standard metric on $X$ by $d_{G}$ and the metrics on the left cosets $t^{i} H \subset G$ by $d_{t^{i} H}$; the latter are isometric to the word-metric on $H$ corresponding to the generating set $S$.

Given $m \in \mathbb{Z}, n \in \mathbb{N}$, a $\kappa$-qi section over the interval $\llbracket m-n, m+n \rrbracket$ in $T$ is a sequence ${ }^{5}$ $\left\{h_{i} t^{i}\right\}, m \leq i \leq n$, such that for each $i \in[m-n, m+n] \cap \mathbb{Z}, d_{X_{i, i+1}}\left(h_{i} t^{i}, h_{i+1} t^{i+1}\right) \leq \kappa$, where we identify integers $i \in[m-n, m+n]$ with the corresponding vertices of $T$. This inequality is satisfied, in particular, when $d_{X_{i}}\left(h_{i} t^{i}, h_{i+1} t^{i}\right) \leq \kappa-1$. Since the vertex spaces $X_{i}, X_{i+1}$ are qi embedded in $X_{i, i+1}$, after changing $\kappa$ if necessary, we can (and will) identify $\kappa$-qi sections with sequences $\left\{h_{i} t^{i}\right\}$ satisfying the inequality

$$
d_{X_{i}}\left(h_{i} t^{i}, h_{i+1} t^{i}\right)=d_{H}\left(1, t^{-i} h_{i}^{-1} h_{i+1} t^{i}\right)=d_{H}\left(1, f^{-i}\left(h_{i}^{-1} h_{i+1}\right)\right)=\left|f^{-i}\left(h_{i}^{-1} h_{i+1}\right)\right|_{H} \leq \kappa,
$$

[^7]equivalently,
\[

$$
\begin{equation*}
d_{H}\left(f^{-i}\left(h_{i}\right), f^{-i}\left(h_{i+1}\right)\right) \leq \kappa . \tag{2.4}
\end{equation*}
$$

\]

Here is an explicit example:
Example 2.64. Fix $h \in H$. Then $i \mapsto h t^{i}, i \in \mathbb{Z}$, is a 1 -qi section over $T$.
Now, let us see what, respectively, exponential and proper flaring conditions in this context mean in group-theoretic terms. Suppose $\gamma, \gamma^{\prime}$ are two $\kappa$-qi sections over $\llbracket m-$ $n, m+n \rrbracket$, where $m, n \in \mathbb{Z}$, given by maps $i \mapsto a_{i} t^{i}$ and $i \mapsto b_{i} t^{i}$. Then for each integer $i \in[m-n, m+n]$, the fiber-distance equals

$$
d_{t^{i} H}\left(\gamma(i), \gamma^{\prime}(i)\right)=d_{t^{i} H}\left(a_{i} t^{i}, b_{i} t^{i}\right)=d_{H}\left(t^{-i} a_{i} t^{i}, t^{-i} b_{i} t^{i}\right)=d_{H}\left(1, t^{-i} a_{i}^{-1} b_{i} t^{i}\right)=\left|f^{-i}\left(a_{i}^{-1} b_{i}\right)\right|_{H}
$$

If we denote the pair of sections $\left(\gamma, \gamma^{\prime}\right)$ by $\Pi$, then

$$
\Pi_{\max }=\max \left\{\left|f^{-m+n}\left(a_{m-n}^{-1} b_{m-n}\right)\right|_{H},\left|f^{-m-n}\left(a_{m+n}^{-1} b_{m+n}\right)\right|_{H}\right\}
$$

In the special case, when $m=0, n=1$,

$$
\begin{equation*}
\Pi_{\max }=\max \left\{\left|f\left(a_{-1}^{-1} b_{-1}\right)\right|_{H},\left|f^{-1}\left(a_{1}^{-1} b_{1}\right)\right|_{H}\right\} . \tag{2.5}
\end{equation*}
$$

Example 2.65. If $\gamma, \gamma^{\prime}$ are given by the maps $i \mapsto t^{i}$ and $i \mapsto h t^{i}$ respectively, where $h \in H$, then

$$
\Pi_{\max }=\max \left\{\left|f^{-m+n}(h)\right|_{H},\left|f^{-m-n}(h)\right|_{H}\right\} .
$$

Since $G$ acts on itself isometrically via the left multiplication, in order to formulate flaring conditions, without loss of generality, we may assume that the qi sections $\gamma, \gamma^{\prime}$ are defined over intervals of the form $\llbracket-n, n \rrbracket$ (i.e. $m=0$ ) and $\gamma(0)=1$.

One can also reformulate the above conditions and quantities using the notion of pseudo-orbits coming from the theory of dynamical systems.

Definition 2.66. Let $(Y, d)$ be a metric space and $\phi:(Y, d) \rightarrow(Y, d)$ be a homeomorphism. For a number $K$, a $K$-pseudo-orbit of $\phi$ in $Y$ is a biinfinite sequence $\left(y_{i}\right)_{i \in \mathbb{Z}}$ in $Y$ such that for each $i$

$$
d\left(y_{i+1}, \phi\left(y_{i}\right)\right) \leq K
$$

For instance, if $K=0$ then 0-pseudo-orbits are just orbits of $\phi$ (or, more precisely, the cyclic group generated by $\phi$ ) in $Y$. The element $y_{i}$ is called the $i$-th member of the pseudoorbit $\left(y_{i}\right)_{i \in \mathbb{Z}}$.

A partial $K$-pseudo-orbit is the restriction of a $K$-pseudo-orbit sequence to an interval in $\mathbb{Z}$.

Given an automorphism $f$ of the group $H$, set $\phi:=f^{-1}$. We will use $\left(H, d_{H}\right)$ as our metric space $(Y, d)$. For a section $\gamma, \gamma(i)=h_{i} t^{i}$, we define $g_{i}:=\phi^{i}\left(h_{i+1}\right)$. In particular, $g_{0}=h_{1}$. Then the inequality (2.4) is equivalent to

$$
d_{H}\left(\phi\left(g_{i}\right), g_{i+1}\right) \leq \kappa
$$

the $\kappa$-pseudo-orbit condition. In other words, instead of working with $\kappa$-sections, we can work with (partial) $\kappa$-pseudo-orbits. The case of a 1-qi section corresponds to the case when $\left(g_{i}\right)$ is the (partial) $\phi$-orbit of $g_{0}$. Given two sections $\gamma, \gamma^{\prime}$, we note that the corresponding partial pseudo-orbit sequences $\left(g_{i}\right),\left(g_{i}^{\prime}\right)$, satisfy

$$
d_{t^{i} H}\left(\gamma(i), \gamma^{\prime}(i)\right)=d_{H}\left(\phi\left(g_{i}\right), \phi\left(g_{i}^{\prime}\right)\right) .
$$

In particular, for fixed $\phi$, a uniform bound on $d_{t^{i} H}\left(\gamma(i), \gamma^{\prime}(i)\right.$ ) is equivalent to a (possibly different) uniform bound on $d_{H}\left(\phi\left(g_{i}\right), \phi\left(g_{i}^{\prime}\right)\right)$.

We can now restate various flaring conditions:
(1) The linear (Bestvina-Feighn) $\kappa$-flaring condition is equivalent to:

There exist constants $M_{\kappa} \geq 0, \lambda_{\kappa}>1$ and $n_{\kappa} \in \mathbb{N}$ such that for every pair of maps $i \mapsto a_{i} \in H$ and $i \mapsto b_{i} \in H, i \in\left[-n_{\kappa}, n_{\kappa}\right] \cap \mathbb{Z}$, satisfying:
(a) $a_{0}=1,\left|b_{0}\right|_{H} \geq M_{\kappa}$,
(b) $d_{H}\left(f^{-i}\left(a_{i}\right), f^{-i}\left(a_{i+1}\right)\right) \leq \kappa, d_{H}\left(f^{-i}\left(b_{i}\right), f^{-i}\left(b_{i+1}\right)\right) \leq \kappa, i \in[-n, n]$,
we have

$$
\max \left\{d_{H}\left(f^{n}\left(a_{-n}\right), f^{n}\left(b_{-n}\right)\right), d_{H}\left(f^{-n}\left(a_{n}\right), f^{-n}\left(b_{n}\right)\right)\right\} \geq \lambda\left|b_{0}\right|_{H}
$$

(2) The proper $\kappa$-flaring condition is equivalent to:

There exists a constant $M_{\kappa} \geq 0$ and a proper function $\phi_{\kappa}: \mathbb{N} \rightarrow \mathbb{R}_{+}$such that for every pair of maps $i \mapsto a_{i} \in H$ and $i \mapsto b_{i} \in H, i \in \mathbb{Z}$, satisfying:
(a) $a_{0}=1,\left|b_{0}\right|_{H} \geq M_{\kappa}$,
(b) $d_{H}\left(f^{-i}\left(a_{i}\right), f^{-i}\left(a_{i+1}\right)\right) \leq \kappa, d_{H}\left(f^{-i}\left(b_{i}\right), f^{-i}\left(b_{i+1}\right)\right) \leq \kappa, i \in[-n, n]$,
we have

$$
\max \left\{d_{H}\left(f^{n}\left(a_{-n}\right), f^{n}\left(b_{-n}\right)\right), d_{H}\left(f^{-n}\left(a_{n}\right), f^{-n}\left(b_{n}\right)\right)\right\} \geq \phi_{\kappa}(n)
$$

It is also useful to spell out the negation of the proper $\kappa$-flaring condition, which is most apparent as the negation of the bigon property from Corollary 2.49:

There exists elements $g, h \in H$ and pairs sequences of partial $\kappa$-pseudo-orbits $\left(g_{i, n}\right)_{n \in \mathbb{N}}$, $\left(g_{i, n}^{\prime}\right)_{n \in \mathbb{N}}$ of $f$ in $H$ defined for $i \in\left[0, N_{n}\right]$, such that:
(a) For all $n, g_{0, n}=1, g_{N_{n}, n}^{\prime}=g, g_{N_{n}}^{\prime}=h g_{N_{n}}$.
(b) $\lim _{n \rightarrow \infty} \max _{i \in\left[0, N_{n}\right]} d_{H}\left(g_{i, n}, g_{i, n}^{\prime}\right)=\infty$.

Note that, by possibly increasing $\kappa$ to $K:=\kappa+C$, where $C=\max \{|g|,|h|\}$, and working with partial $K$-pseudo-orbits, we can even ensure that $g=1, h=1$ and, hence, $g_{0, n}^{\prime}=1$, $g_{N_{n}, n}=g_{N_{n}, n}^{\prime}$.

We next relate flaring to hyperbolicity properties of the automorphism $f$.
Definition 2.67. (Bestvina, Feighn, [BF92]) Suppose $H$ is a finitely-generated group and $S$ is finite generating set for $H$. Suppose $f: H \rightarrow H$ is an automorphism. We say that $f$ is weakly hyperbolic if there is $m \in \mathbb{N}, \lambda>1$ and a finite subset $E \subset H$, such that for all $h \in H \backslash E$ we have

$$
\lambda|h| \leq \max \left\{\left|f^{m}(h)\right|,\left|f^{-m}(h)\right|\right\} .
$$

We say that $E$ is the exceptional subset. An automorphism is called hyperbolic if the above inequality holds with $E=\emptyset$.

Some remarks are in order regarding this definition.
Remark 2.68. (1) The notion of hyperbolicity of an automorphism was introduced by Bestvina and Feighn in [BF92] (the exceptional subset $E$ was absent). They also proved hyperbolicity of semidirect products $H \rtimes_{f}\langle t\rangle$ of hyperbolic automorphisms of hyperbolic groups, see Corollary in [BF92, section 5]. However, the original Bestvina-Feighn definition is too restrictive if the purpose is to conclude hyperbolicity of semidirect products. Lemma 2.71 below (which is already present in Gersten's paper [Ger98, Corollary 6.9]) shows that hyperbolicity of the semidirect product is equivalent to the weak hyperbolicity of the automorphism.
(2) If $f: H \rightarrow H$ is a weakly hyperbolic automorphism, then for any nontrivial finite group $H_{1}$, the automorphism $f^{\prime}=f \times$ id of $H^{\prime}=H \times H_{1}$ is also weakly hyperbolic but fixes the subgroup $H_{1}$ element-wise and, hence, is not hyperbolic.
(3) In Corollary 2.73 we will prove that for automorphisms of torsion-free hyperbolic groups weak hyperbolicity is equivalent to hyperbolicity.
(4) The only hyperbolic groups which admit weakly hyperbolic automorphisms are the ones commensurable to free products of surface groups and free groups, as follows for instance from [RS94].
(5) The hyperbolicity inequality trivially holds for the trivial element $h=1 \in H$. Suppose that the exceptional subset $E$ is a ball $B(1, r) \subset H$ and that (with $\lambda>1$ ) for $h \notin E,\left|f^{m}(h)\right| \geq \lambda|h|$. Then $f^{m}(h) \notin E$ and, thus, we can apply the same hyperbolicity inequality to $f^{m}(h)$. Clearly,

$$
\left|f^{2 m}(h)\right|=\max \left\{\left|f^{2 m}(h)\right|,\left|f^{-m+m}(h)\right|\right\} \geq \lambda^{2}|h| .
$$

Repeating this argument, we see that for each $i \geq 1$,

$$
\left|f^{i m}(h)\right| \geq \lambda^{i}|h| .
$$

Lemma 2.69. Hyperbolicity and weak hyperbolicity of an automorphism $f: H \rightarrow H$ are independent of the finite generating set of $H$.

Proof. We will verify the claim for the weak hyperbolicity property since the proof for hyperbolicity is identical (with $E=\emptyset$ ).

Suppose $f$ is weakly hyperbolic with respect to a finite generating set $S$, i.e. there exist $m \in \mathbb{N}, \lambda>1$ and a finite subset $E \subset H$ such that

$$
\lambda|h|_{S} \leq \max \left\{\left|f^{m}(h)\right|_{S},\left|f^{-m}(h)\right|_{S}\right\}
$$

for all $h \in H \backslash E$.
Suppose $S^{\prime}$ is another finite generating set of $H$. For any $h \in H$ let $|h|_{S}$ and $|h|_{S^{\prime}}$ denote the word-lengths of $h$ with respect to $S$ and $S^{\prime}$ respectively. Then there is a constant $C>0$ such that $\frac{1}{C}|h|_{S} \leq|h|_{S^{\prime}} \leq C|h|_{S}$ for all $h \in H$. Also, we note that for all $r \in \mathbb{N}$ we have $\lambda^{r}|h|_{S} \leq \max \left\{\left|f^{m r}(h)\right|_{S},\left|f^{-m r}(h)\right|_{S}\right\}$ for all $h \in G \backslash E_{r}$ where

$$
E_{r}=\bigcup_{-(r-1) \leq i \leq r-1} f^{i m}(E)
$$

Hence,

$$
\lambda^{r}|h|_{S^{\prime}} \leq C \lambda^{r}|h|_{S} \leq C \max \left\{\left|f^{m r}(h)\right|_{S},\left|f^{-m r}(h)\right|_{S}\right\} \leq C^{2} \max \left\{\left|f^{m r}(h)\right|_{S^{\prime}},\left|f^{-m r}(h)\right|_{S^{\prime}}\right\}
$$

for $h \in H \backslash E_{r}$. It follows that $C^{-2} \lambda^{r}|h|_{S^{\prime}} \leq \max \left\{\left|f^{m r}(h)\right|_{S^{\prime}},\left|f^{-m r}(h)\right|_{S^{\prime}}\right\}$ for $h \in H \backslash E_{r}$. Thus, if we choose $r=r_{1}$ large enough, we get $\lambda_{1}=C^{-2} \lambda^{r_{1}}>1$ and setting $m_{1}=r_{1} m$, we obtain

$$
\lambda_{1}|h|_{S^{\prime}} \leq \max \left\{\left|f^{m_{1}}(h)\right|_{S^{\prime}},\left|f^{-m_{1}}(h)\right|_{S^{\prime}}\right\}
$$

for all $h \in H \backslash E_{r_{1}}$. Whence $f$ is weakly hyperbolic with respect to the generating set $S^{\prime}$.

Example 2.70. (1) Suppose $H=\pi_{1}(\Sigma)$ where $\Sigma$ is a closed connected hyperbolic surface. Then an automorphism $f$ of $H$ is hyperbolic if and only if it is induced by a pseudo-Anosov automorphism of $\Sigma$, if and only if it has no nontrivial periodic conjugacy classes, if and only if the semidirect product $H \rtimes_{f} \mathbb{Z}$ is hyperbolic. (The equivalence of the last three properties is due to William Thurston, see e.g. [CB88, Ota01]. The equivalence with hyperbolicity of $f$ can be seeing either as a consequence of the pseudoAnosov property or of the combination of Lemma 2.71 and Corollary 2.73.)
(2) If $H=\mathbb{F}_{n}, n \geq 2$, then any automorphism $f \in \operatorname{Aut}(H)$ with no periodic conjugacy classes is hyperbolic (in the sense of Bestvina-Feighn). See Theorem 5.1 in [BFH97].

We refer the reader to $[$ Bri00, DT18, Mut21] for other results in this direction.
Lemma 2.71 ([BF92, Ger98]). If $f$ is weakly hyperbolic, then the tree of metric spaces $X=\Gamma\left(H \rtimes_{f} \mathbb{Z}, S_{G}\right) \rightarrow T=\Gamma(Z, 1)$ - as constructed in the beginning of this subsectionsatisfies the Bestvina-Feighn flaring condition. The converse is also true.

Proof. 1. Suppose $f$ is weakly hyperbolic. Let $R=\max \left\{d_{H}(1, h): h \in E\right\}$ where $E \subset H$ is a finite exceptional subset as in Definition 2.67. Then for all $x \in H$ with $|x|_{H}>R$ we have

$$
\lambda|x| \leq \max \left\{\left|f^{m}(x)\right|,\left|f^{-m}(x)\right|\right\} .
$$

First of all, since the Bestvina-Feighn flaring condition is equivalent to hyperbolicity of $G$ and the latter is equivalent to the hyperbolicity of the semidirect product $H \rtimes_{f^{m}} \mathbb{Z}$ (commensurable to the original group $G$ ), it suffices to consider the case when $m=1$. We will also assume that in the definition of a weakly hyperbolic automorphism the maximum is attained by $\phi=f^{-1}$ rather than $f$ (otherwise, we replace $f$ with $f^{-1}$ ). Then the weak hyperbolicity inequality reads

$$
\begin{equation*}
\lambda|x| \leq|\phi(x)| \tag{2.6}
\end{equation*}
$$

for all $x \in H \backslash E$.
Take $\kappa \geq 1$. As we noted earlier, it suffices to verify the Bestvina-Feighn flaring condition for pairs of $\kappa$-qi sections $\Pi=\left(\gamma, \gamma^{\prime}\right)$ defined over intervals of the form $\llbracket-m, m \rrbracket$, satisfying $\gamma(0)=1, h:=\gamma^{\prime}(0)$, where, as above, $m=1$, such that $\Pi_{0}=|h| \geq M_{\kappa}$ for a suitable uniform constant $M_{\kappa}$. Pick any $\lambda^{\prime}$ in the open interval $(1, \lambda)$; for concreteness, we take $\lambda^{\prime}=\frac{1}{2}(\lambda+1)$. We claim that

$$
\lambda^{\prime}|h|=d_{H}\left(\gamma(0), \gamma^{\prime}(0)\right) \leq d_{t H}\left(\gamma(m), \gamma^{\prime}(m)\right)
$$

Set $\gamma(1)=h_{1} t, \gamma^{\prime}(1)=h_{1}^{\prime} t$. Then (as we noted earlier, after changing $\kappa$ ) the $\kappa$-qi section condition for $\gamma, \gamma^{\prime}$ over the interval $[-1,0]$ is equivalent to the inequalities

$$
\begin{equation*}
d_{H}\left(\phi\left(h_{1}\right), 1\right) \leq \kappa, \quad d_{H}\left(\phi(h), \phi\left(h_{1}^{\prime}\right)\right) \leq \kappa \tag{2.7}
\end{equation*}
$$

We will estimate from below the distance (in $H$ ) between $\gamma(1), \gamma^{\prime}(1)$; according to the computation in (2.5), we need to estimate from below the distance

$$
d_{H}\left(\phi\left(h_{1}\right), \phi\left(h_{1}^{\prime}\right)\right)
$$

By the triangle inequality, combined with the inequalities (2.6) and (2.7), we have

$$
d_{H}\left(\phi\left(h_{1}\right), \phi\left(h_{1}^{\prime}\right)\right) \geq d_{H}(1, \phi(h))-2 \kappa \geq \lambda|h|-2 \kappa .
$$

Then the desired inequality $\lambda^{\prime}|h| \leq d_{t H}\left(\gamma(1), \gamma^{\prime}(1)\right)$ is equivalent to

$$
\left(\lambda-\lambda^{\prime}\right)|h| \geq 2 \kappa
$$

By out choice of $\lambda^{\prime}$, this amounts to

$$
|h| \geq \frac{2 \kappa}{\lambda-1}
$$

Therefore, taking $M_{\kappa}$ equal to the maximum of $\frac{2 \kappa}{\lambda-1}$ and $1+\operatorname{diam}_{H}(E)$, we ensure the Bestvina-Feighn flaring condition.
2. For the converse one applies the flaring condition to $\kappa=1$-qi sections. More precisely, we work with pairs of sections as in Example 2.65. We take the finite set in the definition of weak hyperbolicity to be $E=\left\{h \in H:|h|_{H} \leq M_{1}\right\}$. The rest is straightforward and hence left as an exercise for the reader.

Lemma 2.72. Suppose that $H$ is a hyperbolic group, $f: H \rightarrow H$ is weakly hyperbolic. Then the exceptional subset of $E$ can be chosen to contain only finite order elements.

Proof. Let $E \subset H$ be an exceptional subset of $f$, i.e. there exist $m \in \mathbb{N}, \lambda>1$ such that

$$
\lambda|h| \leq \max \left\{\left|f^{m}(h)\right|,\left|f^{-m}(h)\right|\right\}
$$

for all $h \in H \backslash E$. After replacing $f$ with $f^{m}$, we can assume that $\lambda|h| \leq \max \left\{|f(h)|,\left|f^{-1}(h)\right|\right\}$ unless $h \in E$. After enlarging $E$ is necessary, we can assume that it equals to the ball of certain radius $r$ in $H$ (centered at $1 \in H$ ). We define $E^{\prime} \subset E$, the subset consisting of infinite order elements.

Suppose that $h \in E$ is such that for infinitely many values of $m \geq 1$,

$$
\left|f^{m}(h)\right| \leq r
$$

We claim that $h$ has finite order. Indeed, then there exist two numbers $n>m \geq 1$ such that

$$
f^{m}(h)=f^{n}(h), f^{n-m}(h)=h .
$$

It follows that in the group $G=H \rtimes_{f} \mathbb{Z}$ we have

$$
t^{n-m} h=h t^{n-m}
$$

Since $f$ is weakly hyperbolic, the semidirect product $G$ is a hyperbolic group, see Lemma 2.71. Hence, the abelian subgroup $A<G$ generated by $t^{n-m}$ and $h$ is virtually cyclic, i.e. $h$ has finite order.

Thus, as noted above, for each $h \in E^{\prime}$ there exists a smallest natural number $n=n_{h}$ such that $\left|f^{n}(h)\right|>r$, which, in particular, implies that $f^{n}(h) \notin E^{\prime}$. Thus,

$$
\max \left\{\left|f \circ f^{n}(h)\right|,\left|f^{-1} \circ f^{n}(h)\right|\right\} \geq \lambda\left|f^{n}(h)\right| \geq \lambda|h|
$$

Since $n_{h}$ was chosen to be smallest, it follows that the above inequality holds for $f \circ f^{n}(h)=$ $f^{n+1}(h)$. By the same argument as in the proof of Lemma 2.55, we see that for each $m \geq \max \left\{n_{h}: h \in E^{\prime}\right\}$, and $h \in E^{\prime}$,

$$
\lambda|h| \leq\left|f^{m}(h)\right| .
$$

Since the hyperbolicity inequality holds for all $h \in H \backslash E$, we conclude that $f$ satisfies the hyperbolicity condition except for the subset $E^{\prime \prime} \subset E$ consisting of torsion elements.

Corollary 2.73. If $H$ is torsion-free then each weakly hyperbolic automorphism of $H$ is hyperbolic.

## CHAPTER 3

## Flow-spaces, ladders and their retractions

In this chapter we introduce and analyze four classes of subtrees of spaces in hyperbolic trees of spaces:

- Ladders
- Metric bundles
- Carpets
- Flow-spaces

These spaces play key role in proving hyperbolicity and describing geodesics in trees of spaces $(\pi: X \rightarrow T)$ : Uniform quasigeodesics in $X$ will be inductively described as concatenations of uniform quasigeodesics in carpets, ladders and flow-spaces. The main result of this and the next chapter is that all ladders, carpets and flow-spaces are hyperbolic and admit coarse Lipchitz retractions from $X$. We note that our definitions of ladders and flow-spaces are inspired by the ladder construction of Mitra, [Mit98], while the notion of metric bundles is adapted from [MS09].

### 3.1. Semicontinuous families of spaces

All four classes of spaces discussed in this (and the next) chapter are special cases of semicontinuous families of spaces, which are certain subtrees of spaces $\mathfrak{y} \subset \mathfrak{X}$. In what follows, given a subtree of spaces $\mathfrak{V}=(\pi: Y \rightarrow S) \subset \mathfrak{X}=(\pi: X \rightarrow T)$, it will be notationally convenient to extend $\mathfrak{Y}$ ) to a tree of spaces (still denoted $\mathfrak{Y})$ ) over the entire tree $T$ by declaring $Y_{v}=\emptyset, Y_{e}=\emptyset$ for each $v \in V(T)-V(S)$ and $e \in E(T)-E(S)$.

Definition 3.1. Suppose that $\mathfrak{X}=(\pi: X \rightarrow T)$ is a tree of hyperbolic spaces. Fix constants $\lambda \in[0, \infty), E, K \in[1, \infty), D \in[0, \infty]$. We will say that a subtree of spaces $\mathfrak{Y}=(\pi: Y \rightarrow S), S \subset T$, in $\mathfrak{X}$ forms a ( $K, D, E, \lambda$ )-semicontinuous family, relative to a vertex $u \in V(S)$, called the center of $\mathfrak{Y}$, if the following conditions hold:

1. Each vertex/edge space $Y_{v} \subset X_{v}, Y_{e} \subset X_{e}, v \in V(S), e \in E(S)$, is $\lambda$-quasiconvex.
2. Each $y \in \mathcal{Y}$ is connected to $Y_{u}$ by a $K$-leaf $\gamma_{y}$ in $Y$.
3. For each edge $e=[v, w] \in E(T)$ we define the (possibly empty!) projection

$$
\begin{equation*}
Y_{w}^{v}:=P_{X_{v w}, X_{w}}\left(Y_{v}\right) \subset X_{w} . \tag{3.1}
\end{equation*}
$$

We require that whenever $e=[v, w] \in E(S)$ is oriented away from $u$,

$$
\begin{equation*}
\operatorname{Hd}_{X_{v w}}\left(Y_{w}^{v}, Y_{w}\right) \leq E \tag{3.2}
\end{equation*}
$$

and

$$
\begin{equation*}
\operatorname{Hd}_{X_{v w}}\left(Y_{w}, Y_{e}\right) \leq K \tag{3.3}
\end{equation*}
$$

4. For every edge $e=[v, w]$ such that $v \in V(S), w \notin V(S)$, we require the pair of quasiconvex subsets ( $Y_{v}, X_{w}$ ) in $X_{v w}$ to be $D$-cobounded.

Figure 3. A semicontinuous family

Remark 3.2. i. Condition 2 implies that $Y_{w} \subset N_{K}^{e}\left(Y_{v}\right)$, hence, $Y_{w} \subset N_{\eta_{0}(2 K)}\left(Y_{w}^{v}\right)$ with respect to the metric of $X_{w}$. (Recall that $\eta_{0}$ is the distortion function of $X_{v}$ in $X$, hence, in $X_{u v}$.)
ii. Condition 2 in this definition ensures that $Y_{w}$ cannot be "much larger" than $Y_{v}$, while Condition 3 ensures a certain lower bound on $Y_{w}$. Thus, as we move away from $X_{u}$, vertex spaces of $\mathfrak{Y}$ can shrink substantially (even disappear) but they cannot substantially increase.
iii. In most examples in our book, $\lambda=4 \delta_{0}$, hence, we will be suppressing the dependence on this parameter and record only the triple of numbers $(K, D, E)$.
iv. To ensure uniform coboundedness of the pairs $\left(Y_{v}, X_{w}\right)$ in Axiom 4, it suffices to get a uniform upper bound $C$ on the diameters of $Y_{w}^{v}$ : It will then follow that the pair $\left(Y_{v}, X_{w}\right)$ is $D$-cobounded for some $D=D\left(\delta_{0}^{\prime}, \lambda_{0}^{\prime}, C\right)$, see Corollary 1.140.
v. We do not insist on the converse implication in Axiom 4: There will be important situations when we have to consider $\mathfrak{Y}$ 's with uniformly bounded fibers over non-boundary vertices of $S$.
vi. Axioms 3 and 4 will be needed in order to have a uniform coarse Lipschitz retraction $X \rightarrow Y$, see Theorem 3.3.
vii. The edge-spaces $Y_{e}$ of are largely irrelevant for our discussion.
viii. The projections $P_{X_{v w}, X_{w}}$ restricted to $X_{v}$ are at uniformly bounded distance (as measured in $X_{v w}$ ) from the projections $P_{X_{v}, X_{e v}}$. The same, of course, applies to restrictions of the projections $P_{X_{v w}, X_{v}}$. However, we decided to work with the projections $P_{X_{v w}, X_{w}}$ as computations tend to be simpler in this setting.

Theorem 3.3. Suppose that $\mathfrak{Y}$ is $a(K, D, E, \lambda)$-semicontinuous family of spaces with $D<\infty$. Then there exists an $L_{3.3}(K, D, E, \lambda)$-coarse Lipschitz retraction $\rho_{9}: X \rightarrow Y$.

Proof. We will verify that the subtree of spaces $\mathfrak{Y}$ ) is (uniformly) retractible; we use Theorem 2.21 as follows.
(i) We let $h_{v}^{\prime}: X_{v} \rightarrow Y_{v}$ denote the restriction of the nearest-point projections $P_{X_{v v}, Y_{v}}$. According to Theorem 2.21(i), we need to bound the diameter of the image of $X_{e v}$ in $Y_{v}$ under $h_{v}^{\prime}$. However, $X_{e v}$ is contained in the unit neighborhood of $X_{w}$ (taken in $X_{v w}$ ); thus,
we need to bound the diameter of the projection (in $X_{v w}$ ) of $X_{w}$ to $Y_{v}$, which is the content of Axiom 4 of the definition of a semicontinuous family of spaces: This diameter is $\leq D$.
(ii) Assuming that $e=[v, w]$ is an edge of $S$ oriented away from $u$, we need to get a uniform bound

$$
\operatorname{dist}_{X_{v}^{\prime}}\left(h_{v}^{\prime} \circ f_{e v}, f_{e v}^{\prime} \circ h_{e}^{\prime}\right) \leq \text { Const. }
$$

The subsets $Y_{e v}, Y_{e} \subset X_{v w}$ are within unit Hausdorff distance, while

$$
\operatorname{Hd}_{X_{v w}}\left(Y_{e}, Y_{w}\right) \leq E \text { and } \operatorname{Hd}_{X_{v w}}\left(Y_{w}^{v}, Y_{w}\right) \leq E
$$

Since $d_{X_{v w}}\left(Y_{w}, X_{v}\right) \leq K$, by applying Lemma 1.127 to the subsets $U_{1}=X_{v}, U_{2}=Y_{w}$ in $X_{v w}$, we conclude that

$$
\operatorname{Hd}_{X_{v w}}\left(P_{X_{v w}, Y_{v}}\left(X_{w}\right), P_{X_{v w}, X_{w}}\left(Y_{v}\right)\right) \leq 2 \lambda_{0}^{\prime}+3 \delta_{0}^{\prime}+K
$$

Taking into account that the projection $P_{X_{v w}, Y_{v}}$ is uniformly coarse Lipschitz, we conclude that $Y_{e v}$ is uniformly close to the image of $X_{e}$ under the nearest-point projection $P_{X_{v v}, Y_{v}}$ and, accordingly, the nearest-point projection $h_{e}^{\prime}: X_{e} \rightarrow Y_{e}$ is uniformly close to the restriction of the nearest-point projection $X_{v w} \rightarrow P_{X_{v}, Y_{v}}\left(X_{e}\right)$ (see Lemma 1.108). Taking also into account that the map $f_{e v}^{\prime}$ moves points by distance $\leq K$ in $X_{v w}$, we can replace $f_{e v}^{\prime} \circ h_{e}^{\prime}$ with the restriction of the projection $X_{v w} \rightarrow P_{X_{v}, Y_{v}}\left(X_{e}\right)$ to $X_{e}$. Similarly, the map $f_{e v}$ moves points distance $\leq 1$ in $X_{v w}$ and, hence (in view of the uniform coarse Lipschitz property of $h_{v}^{\prime}$ ), we can replace the composition $h_{v}^{\prime} \circ f_{e v}$ with the restriction of the nearest-point projection $P_{X_{v w}, Y_{v}}$ to $X_{e}$. But now, the projections $X_{v w} \rightarrow P_{X_{v}, Y_{v}}\left(X_{e}\right)$ and $P_{X_{v w}, Y_{v}}$ are uniformly close to each other according to Corollary 1.107 applied to the $\lambda_{0}^{\prime}$-quasiconvex subsets $Y_{v}$ and $X_{e}$ in the ambient hyperbolic space $Z=X_{v w}$.

Corollary 3.4. If $\mathfrak{Y})=(\pi: Y \rightarrow S)$ is a $(K, D, E, \lambda)$-semicontinuous family of spaces with $D<\infty$, then the inclusion map $Y \rightarrow X$ is an $L_{3.3}(K, D, E, \lambda)$-qi embedding.

We next describe a class of semicontinuous subtrees of spaces, called metric bundles. The theory of metric bundles was developed in [MS09] in a more general setting when the base is allowed to be an arbitrary geodesic metric space but we will not need that in our book. The following definition of metric bundles is adapted from [MS09] in a form suitable for our purposes. It is easy to verify that the two definitions (ours and that of [MS09]) are equivalent when the base is a tree. The reader should also compare this definition with the notion of an abstract metric bundle given in Definition 2.7: Each metric bundle defined below is also an abstract metric bundle.

Definition 3.5 (Metric bundles). A subtree of spaces $\mathfrak{Y})=(\pi: Y \rightarrow S) \subset \mathfrak{X}=(\pi$ : $X \rightarrow T$ ) is called a $K$-metric bundle if:

1. Every vertex/edge space of $\mathfrak{Y}$ is $\lambda$-quasiconvex in the respective vertex/edge space of $\mathfrak{X}$.
2. For every vertex $u \in V(S)$ and edge $e=[v, w] \in E(S)$ (directed away from $u$ ), and $x \in Y_{w}, x \in Y_{e}$, there exist $K$-qi sections $\gamma_{x}$ in $\mathfrak{Y}$ on $\llbracket w, u \rrbracket$, such that $\gamma_{x}(w)=x$.

It follows immediately that each $K$-metric bundle forms a ( $K, \infty, E, \lambda$ )-semicontinuous family of spaces in $\mathfrak{X}$ (relative to any vertex $u \in S$ ), with $E=\eta_{0}(2 K)$. The reader uncomfortable with using $D=\infty$ here can simply restrict $\mathfrak{X}$ to $S$, then one can take $D=0$.

While Theorem 3.3 does not directly apply to metric bundles $\mathfrak{Y} \subset X($ unless $S=T)$, we will see in Corollary 3.63 that under certain extra assumption weakening condition 4 in Definition 3.1, these too admit uniform coarse Lipschitz retraction from $\mathfrak{X}$.

### 3.2. Ladders

Ladders are certain semicontinuous subtrees of spaces $\mathfrak{L}=(\pi: L \rightarrow S) \subset \mathfrak{X}$ whose fibers are geodesic segments. However, in addition to the properties of a semicontinuous family of spaces, we will impose a certain extra structure on $\mathcal{L}$.

Each ladder $\mathfrak{L}=(\pi: L \rightarrow S)$ comes equipped with certain parameters and two pieces of extra data: An orientation of the fibers (hence, ladders generalize oriented line bundles) and a canonical choice of a maximal $K$-qi section $\Sigma_{x} \subset L$ through each point $x \in L$. The choice of $\Sigma$. can be regarded as a "connection" on $\mathfrak{L}$. Thus, ladders can be regarded as "oriented line semi-bundles equipped with connections."

We will be primarily interested in ladders such that $\mathcal{L}$ is contained in the $4 \delta_{0}$-fiberwise neighborhood of a $k$-flow space $\mathcal{F} l_{k}\left(Q_{u}\right) \subset X$ (these will be defined in Section 3.3). For the ease of notation, we will be ignoring the flow-spaces for now; formally speaking, one can regard the flow-space $\mathfrak{F} l_{k}\left(Q_{u}\right)$ as a tree of hyperbolic spaces satisfying a uniform flaring condition.

We now begin with an axiomatic definition of ladders. Let $\mathfrak{X}=(\pi: X \rightarrow T)$ be a tree of hyperbolic spaces satisfying Axiom $\mathbf{H}$. Fix positive numbers $K, D, E$ and a vertex $u \in T$; these are the parameters of a ladder $\mathfrak{L}$. A ladder with these parameters (a $(K, D, E)$-ladder centered at $u$ ) is a subtree of oriented geodesic intervals in $\mathfrak{X}, \mathcal{L}=(\pi: L \rightarrow S), S=\pi(L)$ which satisfies further axioms described below. Each fiber $L_{v}:=L \cap X_{v}, v \in V(T), L_{e}=$ $L \cap X_{e}, e \in E(T)$, of $\mathfrak{L}$ is an oriented geodesic segment denoted $\left[x_{v} y_{v}\right]_{X_{v}}$ or $\left[x_{e} y_{e}\right]_{X_{e}}$.

Furthermore, we fix once and for all a family $\Sigma_{\text {. of maximal partial } K \text {-qi sections } \Sigma_{x}, ~(1)}$ of $\pi: L \rightarrow S$, whose domains $T_{x}$ are subtrees in $S$ containing the vertex $u$ (and $\pi(x)$, of course). Maximality here is understood in the sense that if $\Sigma_{x}^{\prime}$ is another partial $K$-qi section containing $\Sigma_{x}$, then $\Sigma_{x}=\Sigma_{x}^{\prime}$. The subscript $x$ in $\Sigma_{x}$ indicates that $x \in \Sigma_{x}$. We will assume that $x$ belongs to a vertex-space of $\mathfrak{X}$.

Axiom L0. We will require the family of sections $\Sigma$. to be consistent in the sense that whenever $v=\pi(y)$ is between $u$ and $w=\pi(x)$, the sections $\Sigma_{y}$ and $\Sigma_{x}$ agree on the interval $\llbracket u, v \rrbracket \subset T$.

Definition 3.6. Let $\mathfrak{L}$ be a ladder centered at the vertex $u, L_{u}=\left[x_{u} y_{u}\right]_{X_{u}}$. We will refer to the subsets $\Sigma_{x_{u}}=\operatorname{bot}(\mathfrak{L}), \Sigma_{y_{u}}=\operatorname{top}(\mathfrak{L})$ as, respectively, the bottom and the top of the ladder $\mathfrak{L}$.

Thus, $\Sigma_{\bullet}$ defines a family of maps

$$
\Pi_{w, v}: L_{w} \rightarrow L_{v}
$$

for every vertex $v \in V(S)$ between $u$ and $w \in V(S)$ :

$$
\Pi_{w, v}(x)=\Sigma_{x} \cap L_{v}, x \in \mathcal{L}_{w}
$$

(Note that this intersection is nonempty since $\pi\left(\Sigma_{x}\right)$ is a subtree containing both $w$ and $u$, hence, also containing v.) These maps can be regarded analogues of parallel transport maps in the conventional theory of connections on bundles. Consistency of sections implies the following semigroup property:

$$
\Pi_{w_{1}, w_{3}}=\Pi_{w_{2}, w_{3}} \circ \Pi_{w_{1}, w_{2}}
$$

whenever $w_{2}, w_{3}$ belong to the interval $\llbracket u, w_{1} \rrbracket$ and appear there in the following order:

$$
u \leq w_{3} \leq w_{2} \leq w_{1}
$$

As we will see below, axioms of a ladder require each map $\Pi_{w, v}$ to be either constant or an orientation-preserving topological embedding. The maps $\Pi_{w, v}$ need not be surjective; for every oriented edge $e=[v, w]$ in $S$ (oriented away from $u$ ) we have an oriented subsegment

$$
L_{v}^{\prime}=\left[x_{v}^{\prime} y_{v}^{\prime}\right]_{X_{v}}:=\Pi_{w, v}\left(L_{w}\right)
$$

in $L_{v}$. Here $x_{v}^{\prime}=\Pi_{w, v}\left(x_{w}\right), y_{v}^{\prime}:=\Pi_{w, v}\left(y_{w}\right)$. The orientation of the segment $L_{v}^{\prime}$ is then consistent with that of $L_{v}$ (since $\Pi_{w, v}$ is orientation-preserving). Observe also that the mere existence of $K$-qi sections $\Sigma_{x}$ implies some semicontinuity of the ladder $\mathfrak{L}$ : For every edge $e=[v, w] \subset S$ (oriented away from $u$ )

$$
\begin{equation*}
L_{w} \subset N_{K}^{e}\left(L_{v}^{\prime}\right) \subset N_{K}^{e}\left(L_{v}\right), \tag{3.4}
\end{equation*}
$$

where the $K$-neighborhood is taken in the subspace $X_{v w}$ (which is what the superscript $e$ indicates). However, $L_{w}$ can be much smaller than $L_{v}$.

For $\mathfrak{L}$ (equipped with $\Sigma_{\bullet}$ ) to be a ladder, it has to satisfy three further axioms listed below. Note, however, that the assumption that the fibers $L_{v}, L_{e}$ of $\mathfrak{L}$ are geodesic segments ensures Property 1 in Definition 3.1 with $\lambda=\delta_{0}$, while Axiom L1 implies Property 2 in that definition, thus making Axiom L3 somewhat redundant.

We now fix $K \in[1, \infty), E \geq 1$ and $D \in[0, \infty]$. While all other two parameters in the triple $(K, D, E)$ are real numbers, as with general semicontinuous subtrees of spaces, it is convenient to allow for infinite values of the parameter $D$.

Figure 4. Ladder

## Ladder Axioms:

- L1 Each $x \in L$ belongs to some $\Sigma_{x}$.
- L2 Each map $\Pi_{w, v}$ is either constant or is an orientation-preserving topological embedding.
- $\mathbf{L 3} \mathfrak{L}$ is a $\left(K, D, E, \delta_{0}\right)$-semicontinuous family of spaces.

Remark 3.7. In general, $\pi(\operatorname{top}(\mathfrak{L}))$ and $\pi(\operatorname{bot}(\mathfrak{I}))$ are smaller than the base $S$. If

$$
\pi(\operatorname{top}(\mathfrak{L}))=\pi(\operatorname{bot}(\mathfrak{L}))=S
$$

then $\mathfrak{P}$ will be a $K$-metric bundle. This will happen in the important case of carpets.

Definition 3.8. A $(K, D, E)$-ladder in $\mathfrak{X}$ is a subtree of spaces

$$
\mathfrak{L}=(\pi: L \rightarrow S) \subset \mathfrak{X}=(\pi: X \rightarrow T)
$$

whose vertex and edge-spaces are oriented geodesic segments, equipped with a family of $K$-qi sections $\Sigma$. and satisfying Axioms L0-L3.

Example 3.9. Let $x$ be a point in $X_{u}$ and let $\Sigma_{x}$ be a $K$-qi section of $\pi: X \rightarrow T$ defined over a subtree $S \subset T$ such that $x \in \Sigma_{x}$. Then $L=\Sigma_{x}$ is the total space of a $\left(K, 0, \eta_{0}(2 K)\right.$ )ladder.

Definition 3.10. A subladder in $\mathfrak{L}$ is a ladder $\mathfrak{Z}^{\prime}=\mathfrak{L}\left(\alpha^{\prime}\right) \subset \mathfrak{L}=\mathfrak{Q}(\alpha)$ with the same center $u$ as $\mathfrak{L}$, such that the sections $\Sigma_{\bullet}^{\prime}$ of $\mathfrak{L}^{\prime}$ are restrictions of the sections $\Sigma_{\bullet}$ of $\mathfrak{L}$. In particular, top and the bottom of $\mathfrak{Z}^{\prime}$ are contained in sections of $\mathfrak{L}$ through the end-points of $\alpha^{\prime}$.

In what follows, given a ladder $\mathfrak{L}=\mathfrak{L}_{K}(\alpha), \alpha \subset X_{u}$, for each point $x \in \mathcal{L}$ let $\gamma_{x} \subset \Sigma_{x} \subset$ $L$ denote the section over the interval $\llbracket u, \pi(x) \rrbracket$, connecting $x$ to a point in $\alpha$. Similarly, given two points $x, y \in \mathcal{L}$, if $\Sigma_{x} \cap \Sigma_{y} \neq \emptyset$ and the restriction of $\pi$ to $\Sigma_{x} \cup \Sigma_{y}$ is 1-1, then there exists a unique $K$-leaf $\gamma_{x, y}$ in $\Sigma_{x} \cup \Sigma_{y} \subset \mathcal{L}$ connecting $x$ to $y$.

We omit a proof of the next lemma as it is straightforward:
Lemma 3.11 (Bisecting a ladder). Suppose $u \in V(T), \alpha=[x y]_{X_{u}} \subset X_{u}$ and we are given a ladder $\mathfrak{L}=\mathfrak{L}_{K, D, E}(\alpha)$. Then for every point $z \in[x y]_{X_{u}}$ the $K$-qi section $\Sigma_{z} \subset \mathcal{L}$ decomposes $\mathfrak{Z}$ into two $(K, D, E)$-subladders $\mathfrak{L}^{+}, \mathfrak{Q}^{-}$such that
(1) $L_{u}^{+}=[z y]_{X_{u}} \subset \alpha, L_{u}^{-}=[x z]_{X_{u}} \subset \alpha$,

$$
\begin{equation*}
\operatorname{top}\left(\mathfrak{L}^{-}\right)=\Sigma_{z}=\operatorname{bot}\left(\mathfrak{Q}^{+}\right) . \tag{2}
\end{equation*}
$$

Applying this lemma twice, we obtain:
Corollary 3.12 (Trisecting a ladder). Suppose $u \in V(T), \alpha=[x y]_{X_{u}} \subset X_{u}$ and we are given a ladder $\mathfrak{L}=\mathfrak{L}_{K, D, E}(\alpha)$. Then for every subsegment $\alpha^{\prime}=\left[x^{\prime} y^{\prime}\right]_{X_{u}} \subset \alpha$ there exists a subladder $\mathfrak{Z}^{\prime}=\mathfrak{L}_{K, D, E}\left(\alpha^{\prime}\right) \subset \mathfrak{L}$ bounded by the $K$-qi sections $\Sigma_{x^{\prime}}, \Sigma_{y^{\prime}} \subset \mathfrak{Z}$ (its bottom and top respectively).

Since a $(K, D, E)$-ladder $\mathfrak{P}=(\pi: L \rightarrow S)$ is a $\left(K, D, E, \delta_{0}\right)$-semicontinuous subtree of spaces in $\mathfrak{X}$, as an application of the retraction Theorem 3.3 we obtain:

Corollary 3.13 (Retraction to ladders). For every ( $K, D, E$ )-ladder $\mathfrak{Z}=(\pi: L \rightarrow S)$ there exists a $L_{3.3}\left(K, D, E, \delta_{0}\right)$-coarse Lipschitz retraction $\rho_{\mathfrak{Q}}: X \rightarrow L$.

We next define carpets which are both ladders and metric bundles. While in Axiom L3 of a ladder we assume that fibers over all boundary vertices of $S$ have uniformly bounded diameter when projected to adjacent vertex-spaces $X_{w}, w \notin V(S)$, in the definition of carpets (where the base $S$ is an oriented interval $\llbracket u, w \rrbracket$ ) we will allow one of the boundary vertices of $S$ (namely the vertex $u$ ) to violate this property (which is why $D=\infty$ ). However, instead, we will add a stronger requirement on the other boundary vertex $w$ and a requirement on the top and the bottom.

Definition 3.14. A $\left(K, \infty, \eta_{0}(2 K)\right)$-ladder $\mathfrak{A}=(\pi: A \rightarrow S) \subset \mathfrak{X}$ is called a $(K, C)$ narrow carpet or just a $(K, C)$-carpet if:

1. $S$ is an interval $\llbracket u, w \rrbracket$ and, furthermore, the top and the bottom of $\mathfrak{A}$ connect the two end-points of $A_{u}$ to that of $A_{w}$, i.e.

$$
\pi(t o p(\mathfrak{H}))=\pi(\operatorname{bot}(\mathfrak{A}))=S .
$$

In this case, we will say that $\mathfrak{A}$ is bounded by the $K$-qi sections $\gamma_{1}=\operatorname{bot}(\mathfrak{Z}), \gamma_{2}=\operatorname{top}(\mathfrak{Q})$ of the carpet. We will refer to $\beta=A_{w}$ as the (narrow) end of the carpet and will say that $\mathfrak{A}$ is from $\alpha=A_{u}$ to $\beta=A_{w}$.
2. $A_{w}$ has length $\leq C$.

We will use the notation $\mathfrak{A}=\mathfrak{A}_{K}(\alpha)$ for such carpets to indicate the two key parameters.
Definition 3.15. A $(K, \infty)$-carpet is called a $K$-hallway.
Remark 3.16. 1. Every $K$-hallway is a $K$-metric bundle.
2. The pair of sections $\gamma_{1}, \gamma_{2}$ determines a hallway $\mathfrak{A}$ "coarsely uniquely": The ambiguity in the definition comes from the choice of the vertical geodesics $A_{t}, t \in V(S)$, and, hence, is uniformly controlled. Therefore, in what follows, we will ignore this ambiguity.

The next lemma establishes existence of ladder and hallway structures on subsets in $X$ which are unions of vertical geodesic segments.

Lemma 3.17. Suppose that $\mathfrak{X}$ is a tree of hyperbolic spaces. There exists a function $K^{\prime}=K_{3.17}^{\prime}(K)$ such that the following holds:
a0. Suppose that $\mathcal{L} \subset \mathcal{X}$ is a subset whose projection to $T$ is the vertex-set of a subtree $S \subset T$ containing a vertex u satisfying:
a1. Every fiber $L_{v}=\mathcal{L} \cap X_{v}, v \in V(S)$, is an oriented geodesic segment $\left[x_{v} y_{v}\right]_{X_{v}}$ in $X_{v}$.
a2. $\mathcal{L}$ satisfies Property 4 of a semicontinuous family of spaces with the parameter D. Furthermore, in line with Property 3, for every oriented away from u edge $e=[v, w] \in$ $E(S), \operatorname{Hd}_{X_{v v}}\left(L_{w}^{v}, L_{w}\right) \leq E$, where, as before,

$$
L_{w}^{v}=P_{X_{v w}, X_{w}}\left(L_{v}\right) \subset X_{w} .
$$

a3. Points $x_{w}, y_{w}$ are within distance $K\left(\right.$ in $\left.X_{v w}\right)$ from points $x_{v}^{\prime}, y_{v}^{\prime} \in L_{v}$ respectively, so that

$$
x_{v} \leq x_{v}^{\prime} \leq y_{v}^{\prime} \leq y_{v}
$$

on the oriented segment $L_{v}$.
Then $\mathcal{L} \subset X$ is the union of vertex-spaces of a $\left(K^{\prime}, D, E\right)$-ladder $\mathfrak{L} \subset \mathfrak{X}$ centered at $u$.
b0. Suppose that $\mathcal{A} \subset \mathcal{X}$ is a subset whose projection to $T$ is the vertex-set of an interval $S=\llbracket u, w \rrbracket \subset T$ such that:
b1. Every fiber $A_{v}, v \in V(S)$, of $\mathcal{A}$, is an oriented geodesic segment $\left[x_{v} y_{v}\right]_{X_{v}}$ in $X_{v}$.
b2. For every edge $\left[v_{1}, v_{2}\right]$ in $S, d_{X_{v_{1} v_{2}}}\left(x_{v_{1}}, x_{v_{2}}\right) \leq K, d_{{V_{v_{1}} v_{2}}}\left(y_{v_{1}}, y_{v_{2}}\right) \leq K$.
Then $\mathcal{A}$ is the union of vertex-spaces of a $K^{\prime}$-hallway $\mathfrak{A} \subset X$.
Proof. Our first goal is to define the function $K^{\prime}$.
We let $r^{\prime}:=D_{1.54}\left(\delta_{0}^{\prime}, L_{0}^{\prime}, K\right)$ be given by Lemma 1.54. For $k=K_{1.13}\left(r^{\prime}, L_{0}^{\prime}\right)$ given by Lemma 1.13, we let $\lambda^{\prime}=k_{1.24}(k)$ be given by Lemma 1.24. Lastly, set

$$
K^{\prime}:=r^{\prime}+D_{1.24}(k) .
$$

We now prove the lemma.
a. We define inductively the projections $\Pi_{v_{1}, v_{2}}$ (where $e=\left[v_{1}, v_{2}\right]$ is an edge in $S$ oriented away from $u$ ), as well as the edge-spaces $L_{e}$.

Suppose that for the subtree $B_{n} \subset S$, which is the closed $n$-ball centered at $u$, we defined (partial) $K$-qi sections $\Sigma$ and maps $\Pi$ satisfying all the requirements of a ladder with respect to the parameter $K^{\prime}$.

We extend the definitions of these sections and maps to the vertices in the ball $B_{n+1} \subset S$ as follows. Let $e=\left[v_{1}, v_{2}\right]$ be an edge of $S$ with $v_{1} \in B_{n}, v_{2} \notin B_{n}$. Let $L_{v_{1}}^{\prime}$ denote the
oriented subsegment of $L_{v_{1}}$ bounded by $x_{v_{1}}^{\prime}, y_{v_{1}}^{\prime}$ respectively. Similarly, we define the edgespace $L_{e}$ as the oriented geodesic segment in $X_{e}$ spanned by the nearest-point projections of the end-points $x_{v_{2}}, y_{v_{2}}$ of $L_{v_{2}}$.

According to Lemma 1.54, we have

$$
\begin{gathered}
\operatorname{Hd}_{X_{v_{1} v_{2}}}\left(L_{v_{1}}^{\prime}, L_{v_{2}}\right) \leq r^{\prime}=D_{1.54}\left(\delta_{0}^{\prime}, L_{0}^{\prime}, K\right) \leq K^{\prime} \\
\operatorname{Hd}_{X_{v_{1} v_{2}}}\left(L_{e}, L_{v_{2}}\right) \leq r^{\prime}
\end{gathered}
$$

These conditions ensure Property 3 of Definition 3.1, i.e. Axiom L3 of a ladder.
By Lemma 1.13, we extend the map $x_{v_{2}} \mapsto x_{v_{1}}^{\prime}, y_{v_{2}} \mapsto y_{v_{1}}^{\prime}$ to a $k=K_{1.13}\left(r^{\prime}, L_{0}^{\prime}\right)$ quasiisometry of geodesic segments $q: L_{v_{2}} \rightarrow L_{v_{1}}^{\prime}$, which moves each point distance $\leq r^{\prime}$ (with respect to the metric of $X_{v_{1} v_{2}}$ ). Applying Lemma 1.24, we can replace the quasiisometry $q$ by an increasing homeomorphism $\tilde{q}$ (or a constant function) within distance $D_{1.24}(k)$ from $q$, such that $\tilde{q}$ is a $k_{1.24}(k)$-quasiisometry.

Since $q$ was moving every point of $L_{v_{2}}$ at most distance $r^{\prime}$, it follows that $\tilde{q}$ moves every point within distance $K^{\prime}=r^{\prime}+D_{1.24}(k)$ in $X_{v_{1} v_{2}}$. We set

$$
\Pi_{v_{2}, v_{1}}:=\tilde{q}
$$

Thus, we obtain maps $\Pi_{w, v}: L_{v_{2}} \rightarrow L_{v_{1}}$ for oriented edges $\left[v_{1}, v_{2}\right.$ ] of the tree $S=\pi(\mathcal{L})$, such that $d_{{v_{1}, v_{2}}^{2}}\left(x, \Pi_{v_{2}, v_{1}}(x)\right) \leq K^{\prime}, x \in L_{v_{2}}$. For vertices $v_{1}, v_{2}$ of $S$ such that $v_{1}$ is between $u$ and $v_{2}$ we define the map $\Pi_{v_{2}, v_{1}}: L_{v_{2}} \rightarrow L_{v_{1}}$ as the composition of maps defined for the sequence of edges connecting $v_{2}$ to $v_{1}$. If $\Pi_{v_{2}, v_{1}}$ is injective, then for $z \in L_{v_{1}}^{\prime}$ we define the section $\Sigma_{z} \cap L_{v_{2}}$ as

$$
\Pi_{v_{2}, v_{1}}^{-1}(z) .
$$

If the map is not injective, i.e. constant, we choose an arbitrary point in $L_{v_{2}}$ as $\Sigma_{z} \cap L_{v_{2}}$.
b. The proof of this part is exactly the same as of Part a, except that we use $x_{v_{1}}^{\prime}=$ $x_{v_{1}}, y_{v_{1}}^{\prime}=y_{v_{1}}$.

### 3.3. Flow-spaces

3.3.1. $K$-flow spaces and Mitra's retraction. Suppose that $\mathfrak{X}=(\pi: X \rightarrow T)$ is a tree of hyperbolic spaces. We fix a vertex $u \in T$, the center of the flow and orient all edges $e=[v, w]$ of $T$ so that $v$ is closer to $u$ than $w$. For each $4 \delta_{0}$-quasiconvex subset $Q_{u} \subset X_{u}$ we will define the $K$-flow-space

$$
\mathfrak{F} l_{K}\left(Q_{u}\right)=\left(\pi: F l_{K}\left(Q_{u}\right) \rightarrow S\right) \subset \mathfrak{X}
$$

which, unlike ladders and carpets, depends only on $Q_{u}$ and on $K$, and which will be a ( $K, D, E, 4 \delta_{0}$ )-semicontinuous family of spaces (relative to the vertex $u$ ), with the parameter $E$ depending only on $K$ and $D=D_{0}$, where

$$
\begin{equation*}
D_{0}=D_{1.139}\left(\delta_{0}^{\prime}, \lambda_{0}^{\prime}\right) \tag{3.5}
\end{equation*}
$$

is independent of $K$.
However, for the construction to work, the parameter $K$ has to be sufficiently large, specifically, $K \geq K_{0}$, where $K_{0}$ (which depends only on the parameters of the tree of spaces $\mathfrak{X}$ ) is given by the equation (2.3). As before, we will use $\mathcal{F} l_{K}\left(Q_{u}\right)$ to denote the union of vertex-spaces of $\mathfrak{F} l_{K}\left(Q_{u}\right)$. We first compute the auxiliary parameter $E$ and a certain parameter $R$ (depending on $K$ ) which will be used to define the $K$-flow.

Suppose that $\lambda \geq \frac{3}{2} \delta_{0}$. Recall (Lemma 1.110) that if the image of a subset $Q$ of $X_{v}$ is $\lambda$-quasiconvex in $X_{v w}$ then $Q$ is $\hat{\lambda}$-quasiconvex in $X_{v}$ with

$$
\begin{equation*}
\hat{\lambda}=1500\left(L_{0}^{\prime} \lambda\right)^{3} \tag{3.6}
\end{equation*}
$$

Take

$$
\begin{equation*}
R \geq R_{0}:=\max \left(2\left(\lambda_{0}^{\prime}+\delta_{0}^{\prime}\right), R_{1.145}\left(\delta_{0}^{\prime}, \lambda_{0}^{\prime}\right)\right)=2 \lambda_{0}^{\prime}+5 \delta_{0}^{\prime} \tag{3.7}
\end{equation*}
$$

Set (cf. (3.6))

$$
\begin{gather*}
\lambda^{\prime}:=1500\left(L_{0}^{\prime}\left(R+2 \delta_{0}^{\prime}\right)\right)^{3},  \tag{3.8}\\
E:=2\left(2 \lambda_{0}^{\prime}+3 \delta_{0}^{\prime}+R\right)+\left(\lambda^{\prime}+\delta_{0}\right) . \tag{3.9}
\end{gather*}
$$

While our proofs will work whenever

$$
\begin{equation*}
K \geq R+\lambda^{\prime}+\delta_{0} \tag{3.10}
\end{equation*}
$$

concretely, we will use

$$
\begin{equation*}
K=R^{\wedge}:=\left(15 L_{0}^{\prime} R\right)^{3} \text {, i.e. } R=K^{\vee}:=\frac{1}{15 L_{0}^{\prime}} K^{1 / 3} \tag{3.11}
\end{equation*}
$$

(The reader will verify that this $K$ satisfies the inequality (3.10).) Thus, the inequality (3.7) translates into the inequality

$$
\begin{equation*}
K \geq K_{0}=15^{3}\left(2 \lambda_{0}^{\prime}+5 \delta_{0}^{\prime}\right)^{3}\left(L_{0}^{\prime}\right)^{3} \tag{3.12}
\end{equation*}
$$

Note also that (3.9) makes $E$ a function of $K$

$$
\begin{equation*}
E=E_{3.13}(K) \tag{3.13}
\end{equation*}
$$

while and $R$ also becomes a function of $K$.
We inductively define $4 \delta_{0}$-quasiconvex subsets $Q_{v} \subset X_{v}, Q_{e} \subset X_{e}, v \in V(T), e \in E(T)$, and, at the same time, verify conditions of Definition 3.1 for the collection of subsets $Q_{v}, Q_{e}$, aiming eventually to Prove Theorem 3.20. Assuming that for $v \in V(T)$ a $4 \delta_{0^{-}}$ subset $Q_{v} \subset X_{v}$ is defined, for the oriented edge $e=[v, w]$ of $T$ (oriented away from $u$ ) we set

$$
Q_{w}^{v}:=P_{X_{v w}, X_{w}}\left(Q_{v}\right), \quad Q_{w}^{\prime}:=N_{R}^{e}\left(Q_{v}\right) \cap X_{w}
$$

According to Corollary 1.128,

$$
\operatorname{Hd}_{X_{v w}}\left(Q_{w}^{v}, Q_{w}^{\prime}\right) \leq 2\left(2 \lambda_{0}^{\prime}+3 \delta_{0}^{\prime}+R\right)
$$

Note that both $X_{w}, Q_{v}$ are $\lambda_{0}^{\prime}$-quasiconvex in $X_{v w}$.
Furthermore, by Lemma 1.126, since $R \geq R_{0} \geq 2 \lambda_{0}^{\prime}+2 \delta_{0}^{\prime}$, the intersection $Q_{w}^{\prime}:=$ $N_{R}^{e}\left(Q_{v}\right) \cap X_{w}$ is $\lambda_{1.126}=R+2 \delta_{0}^{\prime}$-quasiconvex in $X_{v w}$. Hence, $Q_{w}^{\prime}$ is $\lambda^{\prime}=\widehat{R+2 \delta_{0}^{\prime}}$-quasiconvex in $X_{w}$, where

$$
\lambda^{\prime}=1500\left(L_{0}^{\prime}\left(R+2 \delta_{0}^{\prime}\right)\right)^{3}
$$

see Lemma 1.110.
Therefore, by (1.3), the $\delta_{0}$-hull, taken in $X_{w}$,

$$
Q_{w}:=\operatorname{Hull}_{\delta_{0}}\left(Q_{w}^{\prime}\right)
$$

is $\left(\lambda^{\prime}+\delta_{0}\right)$-Hausdorff close to $Q_{w}^{\prime}$, thus,

$$
\operatorname{Hd}_{X_{v w}}\left(Q_{w}^{v}, Q_{w}\right) \leq E=2\left(2 \lambda_{0}^{\prime}+3 \delta_{0}^{\prime}+R\right)+\left(\lambda^{\prime}+\delta_{0}\right)
$$

verifying the condition (3.2) in Part 3 of a semicontinuous family of spaces (in the case when $Q_{w}^{\prime} \neq \emptyset$, equivalently, $Q_{w} \neq \emptyset$ ).

We define the edge-space $Q_{e}$ as the $\delta_{0}$-null (in $X_{e}$ ) of the projection

$$
P_{X_{v v}, X_{e}}\left(Q_{w}\right) .
$$

Thus,

$$
\operatorname{Hd}_{X_{v w}}\left(Q_{w}^{v}, Q_{e}\right) \leq \delta_{0}+1
$$

At the same time, since each point of $Q_{w}^{\prime}$ is within distance $R$ from $Q_{v}$, each point of $Q_{w}$ is within distance

$$
R+\lambda^{\prime}+\delta_{0}
$$

from $Q_{v}$, where both distances are computed in $X_{v w}$. Since

$$
K=\left(15 L_{0}^{\prime} R\right)^{3} \geq R+\lambda^{\prime}+\delta_{0}
$$

we conclude that each point of $Q_{w}$ is within distance $K$ from $Q_{v}$. From this, since $Q_{e}$ was defined as the projection of $Q_{w}$ to $X_{e}$, it also follows that $\operatorname{Hd}_{X_{v w}}\left(Y_{w}, Y_{e}\right) \leq K$. Thus, we verified Part 3 of Definition 3.1 (for the edge $e$ ). Since the subsets $Q_{w}, Q_{e}$ were defined as $\delta_{0}$-hulls in $\delta_{0}$-hyperbolic spaces, we conclude that $Q_{e} \subset X_{e}, Q_{w} \subset X_{w}$ are $4 \delta_{0}$-quasiconvex, verifying Part 1 of Definition 3.1.

Lastly, we turn to Part 4 of Definition 3.1. As we noted earlier, $Q_{w}=\emptyset$ if and only if $Q_{w}^{\prime}=N_{R}^{e}\left(Q_{v}\right) \cap X_{w}=\emptyset$. In other words, the $\lambda_{0}^{\prime}$-quasiconvex subsets $Q_{v}, X_{w} \subset X_{v w}$ are $R$-separated. Since $R$ was chosen to satisfy

$$
R \geq R_{0}=R_{1.139}\left(\delta_{0}^{\prime}, \lambda_{0}^{\prime}\right)=2 \lambda_{0}^{\prime}+5 \delta_{0}
$$

Corollary 1.139 implies that subsets $Q_{v}, X_{w} \subset X_{v w}$ are $D=D_{1.139}\left(\delta_{0}^{\prime}, \lambda_{0}^{\prime}\right)$-cobounded. This verifies Part 4 of Definition 3.1.

Definition 3.18. We define the $K$-flow space $\mathfrak{F} l_{K}\left(Q_{u}\right)$ of $Q_{u}$ as the subtree of spaces in $\mathfrak{X}$ as follows. The nonempty subsets $Q_{v}, Q_{e}$ defined by the inductive procedure above will be the vertex/edge spaces of $\mathfrak{F} l_{K}\left(Q_{u}\right)$. The incidence maps $g_{e v}$ of $\mathfrak{F} l_{K}\left(Q_{u}\right)$ are the compositions of the incidence maps $f_{e v}$ with fiberwise nearest-point projections in $X_{v}$ to $Q_{v}$. The vertex and edge-spaces of $\mathfrak{F} l_{K}\left(Q_{u}\right)$ are equipped with path-metrics induced from the ambient path-metrics on vertex and edge-spaces of $\mathfrak{x}$. We let $F l_{K}\left(Q_{u}\right) \subset X$ denote the total space of $\mathfrak{F} l_{K}\left(Q_{u}\right)$, set $S:=\pi\left(F l_{K}\left(Q_{u}\right)\right)$; we will use the notation $\mathcal{F} l_{K}\left(Q_{u}\right)$ for the disjoint union

$$
\coprod_{v \in V(S)} Q_{v},
$$

which is the union of vertex-spaces of $\mathfrak{F} l_{K}\left(Q_{u}\right)$. We will equip $F l_{K}\left(Q_{u}\right)$ with the standard path-metric of a tree of spaces.

Sometimes it will be convenient to restrict flow-spaces to subtrees $T^{\prime} \subset T$. We will denote such "subflows" by

$$
\mathfrak{F} l_{K}^{T^{\prime}}\left(Q_{u}\right) .
$$

Remark 3.19. 1. The $\delta_{0}$-neighborhoods in the definition of flow-spaces are taken in order to ensure that the each inclusion map $Q_{w} \rightarrow X_{w}$ is a $\left(1, C_{1.93}\left(\delta_{0}\right)\right)$-quasiisometric embedding, where $Q_{w}$ is equipped with the path-metric induced from $X_{w}$, see Lemma 1.93.
2. In general, it is not true that for Hausdorff-close subsets $A, B \subset X_{u}$, the $K$-flow spaces are Hausdorff-close to each other. However, if

$$
B \subset N_{r}^{f i b}\left(Q_{u}\right) \subset X_{u}
$$

then (by the very definition of a flow-space)

$$
F l_{K}(B) \subset F l_{K+r}\left(Q_{u}\right)
$$

Similarly,

$$
N_{r}^{f i b}\left(F l_{K}\left(Q_{u}\right)\right) \backslash N_{r}^{f i b}\left(Q_{u}\right) \subset F l_{K+r}\left(Q_{u}\right)
$$

The discussion preceding the definition of flow-spaces proves:

Theorem 3.20. For every $K \geq K_{0}$, the flow-space $\mathfrak{F} l_{K}\left(Q_{u}\right)$ is a ( $K, D, E$ )-semicontinuous family of spaces in $\mathfrak{X}$, where $D=D_{0}=D_{1.139}\left(\delta_{0}^{\prime}, \lambda_{0}^{\prime}\right)$ and $E=E_{3.20}(K)$ is given by the equation (3.9). In particular, every $x \in F l_{K}\left(Q_{u}\right)$ belongs to a $K$-leaf $\gamma_{x}$ in $F l_{K}\left(Q_{u}\right)$ connecting $x$ to $Q_{u}$.

Combining with with the existence of uniform coarse Lipschitz retractions to semicontinuous subtrees of spaces (Theorem 3.3), we conclude:

Theorem 3.21 (Mitra's Retraction). Suppose that $\mathfrak{X}$ is a tree of hyperbolic spaces. Then for each $K \geq K_{0}$, there exists an $L_{3.21}(K)$-coarse Lipschitz retraction, called Mitra's retraction, $\rho=\rho_{F l_{K}\left(Q_{u}\right)}: X \rightarrow F l_{K}\left(Q_{u}\right)$, where

$$
L_{3.21}(K)=L_{3.3}\left(K, D_{0}, E_{3.20}(K), 4 \delta_{0}^{\prime}\right) .
$$

Below we collect several consequences of Theorem 3.21.
Corollary 3.22. The inclusion map $F l_{K}\left(Q_{u}\right) \rightarrow X$ is an $L_{3.21}(K)$-qi embedding.
Corollary 3.23 (M. Mitra, [Mit98]). If X were a hyperbolic metric space then for all $u \in V(T)$ and $4 \delta_{0}$-quasiconvex subsets $Q_{u} \subset X_{u}$, the flow-spaces $F l_{K}\left(Q_{u}\right)$ would be uniformly quasiconvex subsets in $X$.

Corollary 3.24. If $\pi\left(F l_{K}\left(X_{u_{1}}\right)\right) \cap \pi\left(F l_{K}\left(X_{u_{2}}\right)\right)=\emptyset$, then the flow-spaces $F l_{K}\left(X_{u_{1}}\right)$, $F l_{K}\left(X_{u_{2}}\right)$ are $L_{3.21}(K)$-Lipschitz-cobounded in $X$ (cf. Definition 1.25).

Proof. We will be using Mitra's projections

$$
\rho_{i}=\rho_{F l_{K}\left(X_{u_{i}}\right)}, i=1,2 .
$$

Since these projections are $L_{3.21}(K)$-coarsely Lipschitz, it suffices to show that diameters of $\rho_{i}\left(F l_{K}\left(X_{u_{3-i}}\right)\right), i=1,2$, are uniformly bounded. Let $v_{i} \in \pi\left(F l_{K}\left(X_{u_{i}}\right)\right), i=1,2$, denote the vertices realizing the minimal distance between these subtrees of $T$. Let $e_{1}=\left[v_{1}, w_{1}\right]$, $e_{2}=\left[v_{2}, w_{2}\right]$ be the edges incident to $v_{1}, v_{2}$ and contained in the interval $\llbracket v_{1}, v_{2} \rrbracket$ (it is possible that $w_{1}=v_{2}, w_{2}=v_{1}$ ). Then, by the definitions of Mitra's projection (see the proof of Theorem 2.21) and the $K$-flow, for $i=1,2$,

$$
\rho_{3-i}\left(F l_{K}\left(X_{u_{i}}\right)\right) \subset \rho_{3-i}\left(X_{v_{i}}\right)=\left\{x_{3-i}\right\} \subset F l_{K}\left(X_{u_{3-i}}\right) \cap X_{v_{3-i}}
$$

i.e., $\rho_{3-i}\left(F l_{K}\left(X_{u_{i}}\right)\right)$ is the singleton $\left\{x_{3-i}\right\}$. Thus, the flow-spaces $F l_{K}\left(X_{u_{1}}\right), F l_{K}\left(X_{u_{2}}\right)$ are $L_{3.21}(K)$-Lipschitz-cobounded in $X$, see Definition 1.25.

Example 3.25. One can realize the hyperbolic plane as the total space (up to a quasiisometry) of a metric line bundle over a line. Namely, let $T=\mathbb{R}$, where the vertices are the integer points. We will identify $T$ with the $y$-axis in the upper half-plane model of the hyperbolic plane (of course, we parameterize the $y$-axis in $\mathbb{H}^{2}$ by the hyperbolic arc-length). The projection $\pi: \mathbb{H}^{2} \rightarrow T$ is given by the $y$-coordinate of the points in $\mathbb{H}^{2}$. Examples of 1-qi sections of the bundle $\pi: \mathbb{H}^{2} \rightarrow T$ are given by hyperbolic geodesics in $\mathbb{H}^{2}$ which are vertical rays in the half-plane model. For $K=1$, the $K$-flow space of a singleton $Q_{u}=\{q\}$ is then such a hyperbolic geodesic through this point. Mitra's retraction to $L=F l_{K}(Q)$ in this example is within finite distance from the horocyclic projection $\mathbb{H}^{2} \rightarrow L$. While it is 1 -Lipschitz, it is not close to the nearest-point projection $\mathbb{H}^{2} \rightarrow L$. For a general $K \geq 1$, the $K$-flow of a singleton $Q_{u}=\{q\}$ is Hausdorff-close to a geodesic in $\mathbb{H}^{2}$, equivalently, to a $K$-qi section through $q$.
3.3.2. Basic properties of flow-spaces. Most of the time, besides Mitra's retractions and the fact that each flow-space forms a semicontinuous subtree of spaces in $\mathfrak{X}$, instead of the definition of flow-spaces we will use their properties summarized in the next proposition (we recall the equations (3.7) and (3.11) defining the constants $K_{0}, R_{0}$ and the function $\left.R \mapsto R^{\wedge}=K\right)$ :

Proposition 3.26. Suppose that $Q_{u} \subset X_{u}$ is a $4 \delta_{0}$-quasiconvex subset.
(1) Suppose that a vertex $w$ lies between vertices $u$ and $v$. Then for every $r \geq 0$, and all $K \geq K_{0}$,

$$
\begin{equation*}
N_{r}^{f i b}\left(F l_{K}\left(X_{u}\right)\right) \cap N_{r}^{f i b}\left(F l_{K}\left(X_{v}\right)\right) \subset N_{r}^{f i b}\left(F l_{K}\left(X_{w}\right)\right), \tag{3.14}
\end{equation*}
$$

and

$$
\begin{equation*}
N_{r}\left(F l_{K}\left(X_{u}\right)\right) \cap N_{r}\left(F l_{K}\left(X_{v}\right)\right) \subset N_{r}\left(F l_{K}\left(X_{w}\right)\right) \tag{3.15}
\end{equation*}
$$

(2) Suppose that $R \geq R_{0}$ and let $\gamma$ is a $R$-qi leaf in $X$ emanating from some $\gamma(u) \in Q_{u}$. Then $\gamma \cap \mathcal{X}$ is contained in $\mathcal{F} l_{K}\left(Q_{u}\right)$, where $K=R^{\wedge}$.
(3) For all $K \geq R_{0}$ and $Q_{v}:=F l_{K}\left(Q_{u}\right) \cap X_{v}$, we have

$$
Q_{u} \subset F l_{K^{\wedge}}\left(Q_{v}\right)
$$

(4) For every boundary edge $e=[v, w]$ of $S=\pi\left(F l_{K}\left(Q_{u}\right)\right)$, the subsets $Q_{v}, X_{w}$ are $D_{0}$-cobounded in $X_{v w}$, where $D_{0}$ is given by (3.5).

Proof. (1) The first containment follows from the inductive nature of the definition of flows. We now prove the second inclusion. Let $x \in F l_{K}\left(X_{u}\right), y \in F l_{K}\left(X_{v}\right)$ and $z \in$ $\bar{B}(x, r) \cap \bar{B}(y, r) \subset X$. Up to relabeling, there are two cases:
a. $w$ lies in the geodesic segment $\pi(y) v \subset T$. Then $y \in F l_{K}\left(X_{w}\right)$ (according to (3.14) with $r=0$ ), which implies that $z \in N_{r}\left(F l_{K}\left(X_{w}\right)\right)$.
b. The vertex $w$ is not in $u \pi(x) \cup v \pi(y)$, hence, $w$ separates $\pi(x), \pi(y)$ in $T$. Therefore, after relabeling, $w$ separates $\pi(x)$ from $\pi(z)$. In particular the geodesic $x z \subset X$ crosses $X_{w}$ and, hence, $z \in N_{r}\left(X_{w}\right) \subset N_{r}\left(F l_{K}\left(X_{w}\right)\right)$.
(2) The proof is by induction on the distance from vertices of $\pi(\gamma)$ to $u$. We will use the notation Let $Q_{v}, Q_{w}^{\prime}$, etc. as in the definition of the flow-space $F l_{K}\left(Q_{u}\right)$.

The base of induction (for the vertex $u$ ) is clear. Suppose that $e=[v, w]$ is an edge in $\pi(\gamma)$ oriented away from $u$ such that $x=\gamma(v) \in Q_{v}, y=\gamma(w) \in X_{w}$. Arguing inductively, we assume that the claim holds for the point $x$, i.e.

$$
x \in Q_{v}=\mathcal{F} l_{K}\left(Q_{u}\right) \cap X_{v}
$$

Since $\gamma$ is an $R$-qi leaf in $X$,

$$
d_{X_{v w}}(x, y) \leq R
$$

i.e. by the definition of the function $R \mapsto R^{\wedge}=K$,

$$
y \in N_{R}^{e}\left(Q_{v}\right) \cap X_{w}=Q_{w}^{\prime} \subset Q_{w} .
$$

Part (3) is an immediate consequence of (2).
Notation 3.27. In what follows, we will refer to $K$-qi leaves in $F l_{K}\left(Q_{u}\right)$ as leaves in $F l_{K}\left(Q_{u}\right)$ and denote them $\gamma$ with some subscripts. We will use the notation $\gamma_{x}, \gamma_{x, y}$ for such leaves provided that $\gamma$ has $x$ as one of its end-points (in the former case) or $\gamma$ connects $x$ and $y$.

Lemma 3.28. Given any point $x \in F l_{K}\left(X_{u}\right)$, there is a maximal ${ }^{1} K$-qi section $\Sigma_{x}$ in $F l_{K}\left(X_{u}\right)$ over a subtree $T_{x}$ of $T$ such that $x \in \Sigma_{x}$ and $u \in T_{x}$.

Proof. Let $w=\pi(x)$. By Theorem 3.20, there exists a $K$-qi section $\Sigma_{\llbracket u, w \rrbracket, x}$ over the geodesic $\llbracket u, w \rrbracket \subset T$ connecting $u$ and $w$ such that $x \in \Sigma_{\llbracket u, w \rrbracket, x}$. We define a poset consisting of $K$-qi sections $\Sigma_{S, x}$ over subtrees $S \subset T$ and containing $\Sigma_{\llbracket u, w \rrbracket, x}$. Define the partial order $\Sigma_{S, x} \leq \Sigma_{S^{\prime}, x}$ if the qi section $\Sigma_{S^{\prime}, x}$ extends $\Sigma_{S, x}$. This poset is clearly nonempty. The existence of a maximal element in this poset follows from Zorn's lemma.

In chapter 8 we will also use the following property of flow-spaces:
Lemma 3.29. Suppose that $Q_{w}=F l_{K}\left(X_{u}\right) \cap X_{w} \neq \emptyset$. Then $N_{R}\left(F l_{K}\left(X_{u}\right)\right) \cap X_{w}$ is contained in

$$
N_{D}^{f i b}\left(X_{u}\right)
$$

$D=D_{3.29}(R, K)$.
Proof. Let $S$ denote the subtree $S=\pi\left(F l_{K}\left(X_{u}\right)\right) \subset T$. Since $Y=X_{S}$ is $\eta_{0}$-properly embedded in $X$, it suffices to measure distances and consider geodesics in $Y$. Let $v$ be a vertex in $S$ and consider a point $x \in X_{v}$ such that

$$
d_{Y}\left(x, Q_{v}\right) \leq r
$$

and suppose that $y \in X_{w}$ is within distance $R$ from $x$. Our goal is to bound $d_{X_{w}}\left(y, Q_{w}\right)$ in terms of $R$ and $r$. Lemma will then follow by considering the case $r=0$, as

$$
\left.d_{X_{w}}\left(y, Q_{w}\right) \leq \eta_{0}\left(d_{( } y, Q_{w}\right)\right)
$$

Since the length of the projection of $[x y]_{Y}$ to $S$ is bounded from above by $R$, the proof can be done by induction on $d_{S}(v, w)$. The base-case $n=0$ is clear as

$$
d_{Y}\left(y, Q_{w}\right) \leq R+r
$$

Suppose that there is a function $\theta(n, r, R)$ such that if $d_{S}(v, w)=n$, then

$$
d_{Y}\left(y, Q_{w}\right) \leq \theta(n, r, R)
$$

Consider now points $x, y$ such that $d_{S}(v, w)=n+1$.
Let $[z y]_{Y}$ be a subsegment in $[x y]_{Y}$ connecting $z \in X_{t}$ to $y$, such that $d_{S}(t, w)=1$. We will consider the more difficult case when $t$ lies between $u$ and $w$ and leave the case when $w$ is between $u$ and $t$ to the reader. By the induction hypothesis (applied to the points $x, z$ ), there exists $p \in Q_{t}$ such that $d(p, z) \leq \theta(n, r, R)$. Let $\bar{p}$ denote the projection (taken in $X_{t w}$ ) of $p$ to $X_{w}$. Then

$$
d_{Y}\left(\bar{p}, Q_{w}\right) \leq d_{X_{t w}}\left(\bar{p}, Q_{w}\right) \leq E=E_{3.20}(K)
$$

Since $y \in X_{w}$ and

$$
d_{X_{t v}}(p, y) \leq L_{0}^{\prime}(d(p, y)+1) \leq L_{0}^{\prime}(R+\theta(n, r, R)+1)
$$

it follows that $d(p, \bar{p}) \leq L_{0}^{\prime}(R+\theta(n, r, R)+1)$ as well. By combining the inequalities, we obtain:

$$
d_{Y}\left(y, Q_{w}\right) \leq \theta(n+1, r, R):=E+2 L_{0}^{\prime}(R+\theta(n, r, R)+1)
$$

[^8]3.3.3. Generalized flow-spaces. In this section we discuss several generalizations of flow-spaces and retractions to these, generalizing Mitra's projection. We recall (see Definition 3.18) that superscript in the form of a subtree $S \subset T$ in the notation of a flowspace, means that the flow-space is taken in the subtree of spaces $\mathfrak{X}_{S} \subset \mathfrak{X}$ over the subtree $S \subset T$.

Definition 3.30. Assume that $K \geq K_{0}$.

1. We define flow-spaces of quasiconvex subsets $Q_{e} \subset X_{e}$ of edge-spaces, $e=[v, w]$. Define subtrees $T_{v}$ (resp, $T_{w}$ ) in $T$ as the maximal subtree in $T$ containing $v$ (resp. $w$ ) and disjoint from $w$ (resp. $v$ ). We define the flow-space $\mathfrak{F} l_{K}\left(Q_{e}\right)$ of such $Q_{e}$ so that its union of vertex-spaces is

$$
\mathcal{F} l_{K}\left(Q_{e}\right):=\mathcal{F} l_{K}^{T_{v}}\left(\operatorname{Hull}_{\delta_{0}} f_{e v}\left(Q_{e}\right)\right) \cup \mathcal{F} l_{K}^{T_{w}}\left(\operatorname{Hull}_{\delta_{0}} f_{e w}\left(Q_{e}\right)\right)
$$

2. Similarly, we define flow-spaces in $X$ of $X_{S} \subset X$, where $S \subset T$ is a subtree. For each $w \in V(S)$ we define the maximal subtree $T_{w} \subset T$ whose intersection with $S$ equals $\{w\}$. We then define the $K$-flow-space $\mathfrak{F} l_{K}\left(X_{S}\right)$ in $X$ so that $X_{S} \subset \mathfrak{F} l_{K}\left(X_{S}\right)$ and the union of vertex-spaces of $\mathfrak{F} l_{K}\left(X_{S}\right)$ equals

$$
\begin{equation*}
\mathcal{F} l_{K}\left(X_{S}\right)=\bigcup_{v \in V(S)} \mathcal{F} l_{K}^{T_{v}}\left(X_{\nu}\right) \tag{3.16}
\end{equation*}
$$

Corollary 3.31. For oriented edges $e=[u, v]$ of $T$ the inclusion maps

$$
F l_{K}\left(X_{e}\right) \rightarrow F l_{K}\left(X_{u}\right)
$$

are uniformly quasiisometric embeddings.
Proof. Apply Theorem 3.21 to the $\delta_{0}$-quasiconvex hull of $Q_{u}:=f_{e u}\left(X_{e}\right)$ and observe that $F l_{K}\left(X_{e}\right) \subset F l_{K}\left(Q_{u}\right) \subset F l_{K}\left(X_{u}\right)$.

Proposition 3.32. There exists $L=L_{3.32}(K)$ such that for every subtree $S \subset T$ and $K \geq K_{0}$, the flow-space $F l_{K}\left(X_{S}\right)$ is L-qi embedded in $X$.

Proof. We continue with the notation introduced in Definition 3.30. For each $w \in$ $V(S)$ we define Mitra's retraction $\rho_{w}=\rho_{X_{w}}: X_{T_{w}} \rightarrow F l_{K}^{T_{w}}\left(X_{w}\right)$. Hence, the collection of maps $\rho_{w}$ is uniformly coarsely Lipschitz. We then obtain a (uniformly) coarse Lipschitz retraction

$$
X \rightarrow F l_{K}\left(X_{S}\right)
$$

whose restriction to $\pi^{-1}(S)$ is the identity and whose restriction to each $X_{T_{w}}$ equals $\rho_{w}$.
We now define flow spaces of metric bundles. Let $S \subset T$ be a subtree and $\mathfrak{Q}=(\pi$ : $Q \rightarrow S$ ) be a metric $K_{1}$-bundle in $X$ whose vertex spaces $Q_{v} \subset X_{v}$ are $4 \delta_{0}$-quasiconvex subsets. Let $Q=\bigcup_{v} Q_{v}$ denote the union of vertex-spaces of $\mathfrak{Q}$. For each vertex $v \in V(S)$, as above, we have the associated subtree $T_{v} \subset T$, which is the maximal subtree in $T$ such that $T_{v} \cap S=\{v\}$. Accordingly, we have subtrees of spaces $X_{T_{v}} \subset X$.

For each vertex $v \in S$ we take the $K_{2}$-flow-space

$$
\mathcal{F}_{v}:=\mathcal{F} l_{K_{2}}\left(Q_{v}\right) \cap X_{T_{v}}
$$

inside $X_{T_{v}}$. Lastly, set

$$
\mathcal{F} l_{K_{2}}\left(Q_{u}\right):=\bigcup_{v \in V(S)} \mathcal{F}_{v} .
$$

Then, as in the case when $Q$ was the union of vertex spaces $X_{v}, v \in V(S)$ (see in Definition $3.30(2)), \mathcal{F} l_{K_{2}}\left(Q_{u}\right)$ is the union of vertex-spaces of a tree of spaces $\mathfrak{F} l_{K_{2}}(\mathfrak{Q})$.

Definition 3.33. We will refer to $\mathfrak{F} l_{k}(\mathfrak{Q})$ (and its total space $F l_{k}(\mathfrak{Q})$ ) as a generalized $k$-flow-space, or the $k$-flow-space of a metric bundle.

The following is an extension of Mitra's theorem to such generalized flow-spaces:
Theorem 3.34. For every $K_{2} \geq K_{0}$, there exists an $L=L_{3.34}\left(K_{1}, K_{2}\right)$-coarse Lipschitz retraction $X \rightarrow \operatorname{Fl}_{K_{2}}(\mathfrak{Q})$.

Proof. The proof is similar to that of Proposition 3.32. Over subtrees $T_{w}, w \in V(S)$, we use Mitra's retractions $X_{T_{w}} \rightarrow F l_{K_{2}}(\mathfrak{Q}) \cap X_{T_{w}}$. The fact that these maps define a uniformly coarse Lipschitz retraction $X_{S} \rightarrow Q$ (over the three $S$ ) follows from the assumption that $\mathfrak{Q}=(\pi: Q \rightarrow S)$ is a $K_{1}$-bundle, cf. Corollary 2.23.

This theorem will be used in Section 6.1.2.
3.3.4. Boundary flows. In this section we will define ideal boundary flows, which are ideal counterparts of flow-spaces discussed above. Ideal boundary flows will be used only in chapters 7 (specifically, Section 7.3) and 8. The definition of boundary flows given below was latent in [Sar18, Definition 4.3].

Fix a vertex $u \in V(T)$ and consider a subset $Z_{u} \subset \partial_{\infty} X_{u}$. We will define the flow-space $\mathfrak{F} l\left(Z_{u}\right)$ of $Z_{u}$ in $\partial_{\infty} X$, analogously to the definition of flow-spaces $\mathfrak{F} l_{K}\left(Q_{u}\right)$ of quasiconvex subsets $Q_{u} \subset X_{u}$ given in Section 3.3. Each $\mathfrak{F} l\left(Z_{u}\right)=3$ will be a tree of topological spaces over a subtree $S \subset T$, with vertex-spaces $Z_{v} \subset \partial_{\infty} X_{v}$ and edge-spaces $Z_{e} \subset \partial_{\infty} X_{e}$.

Our definition of subsets $Z_{v} \subset \partial_{\infty} X_{v}, Z_{e} \subset \partial_{\infty} X_{e}$, is inductive on $d_{T}(u, v)$, analogously to the definition of $\mathfrak{F} l_{K}\left(Q_{u}\right) \subset X$. We assume that subsets $Z_{v}, Z_{e}$ are defined for all vertices and edges of $T$ contained in the ball (in $T$ ) of radius $n$ centered at $u$. Consider an edge $e=[v, w]$ in $T$ oriented away from $u$, such that $d_{T}(u, v)=n$. We have qi embeddings $f_{e v}: X_{e} \rightarrow X_{v}$ and $f_{e w}: X_{e} \rightarrow X_{w}$. They induce topological embeddings (boundary maps)

$$
\partial_{\infty} f_{e v}: \partial_{\infty} X_{e} \rightarrow \partial_{\infty} X_{v}, \quad \partial_{\infty} f_{e w}: \partial_{\infty} X_{e} \rightarrow \partial_{\infty} X_{w}
$$

see Section 1.13. Define

$$
Z_{e}:=\left(\partial_{\infty} f_{e v}\right)^{-1}\left(Z_{v}\right), \quad \text { and } \quad Z_{w}:=\partial_{\infty} f_{e w}\left(Z_{e}\right)
$$

The boundary maps $\partial_{\infty} f_{e v}, \partial_{\infty} f_{e w}$ provide incidence maps $Z_{e} \rightarrow Z_{v}, Z_{e} \rightarrow Z_{w}$. We continue inductively. Define $S$ as the subtree in $T$ spanned by the vertices $v \in T$ such that $Z_{v} \neq \emptyset$. Thus, we obtain a tree $3=(Z \rightarrow S), Z=F l\left(Z_{u}\right)$, of topological spaces with the vertexspaces $Z_{v}, v \in V(S)$, the edge-spaces $Z_{e}, e \in E(S)$ and incidence maps $\partial_{\infty} f_{e v}$ as above, see Definition 2.5. We will use the notation $\mathcal{F} l\left(Z_{u}\right)$ for $\mathcal{Z}$, the union of vertex-spaces of 3. Note that since the maps $\partial_{\infty} f_{e v}$ are $1-1$, the set $\mathcal{F} l\left(Z_{u}\right)$ breaks as a disjoint union of flow-spaces $\mathcal{F} l(\{z\})$ of singletons $\{z\} \subset Z_{u}$. For each $v \in V(T)$, the intersection

$$
F l_{v}(\{z\}):=\mathcal{F} l(\{z\}) \cap \partial_{\infty} X_{v}
$$

is either empty or is a singleton. Similarly, for each edge $e=[v, w] \in E(T)$, the intersection $F l_{e}(\{z\}):=F l(\{z\}) \cap Z_{e}$ is either empty or is a singleton. In view of the inductive definition of $F l\left(Z_{u}\right)$, if $F l_{w}(\{z\}) \neq \emptyset$ for a vertex $w$, then for every vertex $v \in u w, F l_{v}(\{z\})=\left\{z^{\prime}\right\}$ is also nonempty and we have

$$
F l_{v}\left(\left\{z^{\prime}\right\}\right)=F l_{w}(\{z\})
$$

Furthermore, for each edge $e$ in the interval $u v, F l_{e}(\{z\})$ is nonempty as well. For $z \in$ $\partial_{\infty} X_{u}$ we define a tree $T_{z} \subset S$ such that $V\left(T_{z}\right)$ consists of vertices $v$ for which $F l_{v}(\{z\})$ is nonempty.

The next lemma is partially proven in [Sar18, Lemma 4.4]; we include a proof for the sake of completeness:

Lemma 3.35. Suppose that $\mathfrak{X}=(\pi: X \rightarrow T)$ is a tree of hyperbolic spaces. Consider a point $z \in \partial_{\infty} X_{u}$ and a geodesic ray $\alpha_{u} \subset X_{u}$ asymptotic to $z$. Then for a vertex $v \in V(T)$ the following are equivalent:

1. $F l_{\nu}(\{z\})$ is nonempty.
2. There is a geodesic ray $\alpha_{v} \subset X_{v}$ such that $\operatorname{Hd}\left(\alpha_{u}, \alpha_{v}\right)<\infty$. In this case $F l_{v}(\{z\})=$ $\left\{\alpha_{v}(\infty)\right\}$.
3. $\alpha_{u}$ is Hausdorff-close to a subset of $X_{v}$.

Proof. It suffices to prove the equivalence in the case when $u, v$ span an edge $e=[v, w]$ in $T$ (the general case is proven by induction on $\left.d_{T}(u, v)\right)$. As we noted earlier, $F l_{v}(\{z\})=$ $\left\{z_{v}\right\} \neq \emptyset$ if and only if $F l_{e}(\{z\})=\left\{z_{e}\right\} \neq \emptyset$. The latter holds if and only if there is a geodesic ray $\alpha_{e}$ in $X_{e}$ such that $\alpha_{e}(\infty)=z_{e}$ and

$$
\partial_{\infty} f_{e u}\left(z_{e}\right)=z, \quad \partial_{\infty} f_{e v}\left(z_{e}\right)=z_{v}
$$

The paths $f_{e u}\left(\alpha_{e}\right), f_{e v}\left(\alpha_{e}\right)$ are quasigeodesic rays in $X_{u}$ and $X_{v}$ respectively, which are asymptotic, respectively, to the points $\{z\},\left\{z_{v}\right\}$. By the stability of quasigeodesics we have $\operatorname{Hd}\left(\alpha_{u}, f_{e u}\left(\alpha_{e}\right)\right)<\infty$ and there is a geodesic ray $\alpha_{v}$ in $X_{v}$ Hausdorff-close to $f_{e v}\left(\alpha_{e}\right)$. This proves the equivalence of (1) and (2).

The implication (2) $\Rightarrow(3)$ is clear. If (3) holds, then the image of $\alpha_{u}$ under the projection $P=P_{X_{u v}, X_{v}}$ is again a quasigeodesic in $X_{v}$ (which is Hausdorff-close to $\alpha_{u}$ ). By the stability of quasigeodesics, $P\left(\alpha_{u}\right)$ is Hausdorff-close to a geodesic $\alpha_{v}$ in $X_{v}$.

Corollary 3.36. The following is an equivalence relation on $\bigcup_{v \in V(T)} \partial_{\infty} X_{v}$ :
Two points $z_{i} \in \partial_{\infty} X_{u_{i}}, i=1,2$ are related iff $F l_{u_{2}}\left(\left\{z_{1}\right\}\right)=\left\{z_{2}\right\}$.
We next relate boundary flow-spaces to the flow-spaces in $\mathfrak{F}$.
Lemma 3.37. There is a constant $K$ depending on the parameters of $\mathfrak{X}$ such that the following holds:
(1) If $\alpha_{u} \subset X_{u}$ is a geodesic ray asymptotic to $z \in \partial_{\infty} X_{u}$, then $F l_{v}(\{z\})=\partial_{\infty}\left(F l_{K}\left(\alpha_{u}\right) \cap\right.$ $\left.X_{v}, X_{v}\right)$ for all $v \in V\left(T_{z}\right)$.
(2) $F l_{v}\left(\partial_{\infty} X_{u}\right)=\partial_{\infty}\left(F l_{K}\left(X_{u}\right) \cap X_{v}, X_{v}\right)$ for all $v \in V(T)$.

Proof. (1) The inclusion $\partial_{\infty}\left(F l_{K}\left(\alpha_{u}\right) \cap X_{v}, X_{v}\right) \subset F l_{v}(\{z\})$ is clear, we will prove the opposite inclusion. Suppose first that $v_{1}, v_{2}$ are vertices in the tree of $T_{z}$ satisfying

$$
d_{T}\left(u, v_{2}\right)=d_{T}\left(u, v_{1}\right)+1,
$$

and let $\alpha_{i} \subset X_{v_{i}}, i=1,2$, be geodesic rays such that $F l_{v_{i}}(\{z\})=\left\{\alpha_{i}(\infty)\right\}, i=1,2$. According to Lemma 3.35,

$$
\operatorname{Hd}_{{V_{v_{1} v_{2}}}}\left(\alpha_{1}, \alpha_{2}\right)<\infty
$$

Since $X_{v_{1} v_{2}}$ is $\delta_{0}^{\prime}$-hyperbolic and $\alpha_{1}, \alpha_{2}$ are $L_{0}^{\prime}$-quasigeodesics in $X_{v_{1} v_{2}}$, it follows that there are subrays in $\alpha_{1}^{\prime} \subset \alpha_{1}, \alpha_{2}^{\prime} \subset \alpha_{2}$ which are $R$-Hausdorff close in $X_{v_{1} v_{2}}$, where $R$ depends only on the parameters of $\mathfrak{X}$ (see Corollary 1.84). Set $K:=R^{\wedge}$. Then, if $\alpha_{1}$ is contained in $F l_{K}\left(\alpha_{u}\right)$, then so does $\alpha_{2}^{\prime}$ (see Proposition 3.26(2)). Now, Part (1) of lemma follows by induction on $d_{T}(u, v)$.

Part (2) follows immediately from (1).
3.3.5. Geometry of the flow-incidence graph. In this section we will assume that $K \geq K_{0}$. We will analyze (to some degree) the intersection pattern of projections to $T$ of the flow-spaces $F l_{K}\left(X_{u}\right), u \in V(T)$. Some of these results will be important (specifically, Subdivision Lemma and its corollary, Corollary 3.45) in Chapter 6.

Definition 3.38. An interval $J=\llbracket u, v \rrbracket \subset T$ is special (more precisely, $K$-special) if one of its end-points (say, $u$ ) has the property that $J \subset \pi\left(F l_{K}\left(X_{u}\right)\right)$. In this case, the vertex $u$ is said to be special in $J$.

For instance, for every edge $e=[u, v] \in E(T)$, the interval $J=\llbracket u, v \rrbracket$ is special.
Remark 3.39. The notion of a special interval can be refined and one can say that an oriented interval $J=\llbracket u, v \rrbracket \subset T$ is special if $J \subset \pi\left(F l_{K}\left(X_{u}\right)\right)$. We will not need this refinement.

The importance of special intervals comes from the following simple fact:
Lemma 3.40. Suppose that $u, v \in V(T)$ are such that $\pi\left(F l_{K}\left(X_{u}\right)\right) \cap \pi\left(F l_{K}\left(X_{v}\right)\right)$ contains a vertex $t$. Then the center $w$ of the triangle $\Delta t u v$ subdivides the interval $I=\llbracket u, v \rrbracket$ in two special subintervals

$$
J=\llbracket u, w \rrbracket, J^{\prime}=\llbracket w, v \rrbracket .
$$

Proof. Since $w$ separates $u$ and $v$ from $t$, Proposition 3.26(1) implies that

$$
J \subset \pi\left(F l_{K}\left(X_{u}\right)\right), J^{\prime} \subset \pi\left(F l_{K}\left(X_{v}\right)\right)
$$

Of prime importance for us will be whether intersections as in the lemma are empty or not, since empty intersection will imply that the pair of subsets $F l_{K}\left(X_{u}\right), F l_{K}\left(X_{v}\right)$ of $X$ is $L_{3.21}(K)$-Lipschitz cobounded, see Corollary 3.24. This observation motivates the following definition:

Definition 3.41. For each $K$ we define the flow-incidence graph $\Gamma=\Gamma_{K}$. Its vertexset is $V(T)$. Two vertices $u, v$ of $\Gamma$ are connected by an edge $e \in E(\Gamma)$ if and only if $\pi\left(F l_{K}\left(X_{u}\right)\right) \cap \pi\left(F l_{K}\left(X_{v}\right)\right) \neq \emptyset$.

Lemma 3.40 implies:
Corollary 3.42. $d_{\Gamma}(u, v) \leq 1$ if and only if the interval $\llbracket u, v \rrbracket$ is the union of two special subintervals.

While the graph $\Gamma$ is not necessarily a tree, we will see that it is a quasi-tree. Recall that a geodesic metric space $Y$ is called a quasi-tree (see Manning's paper [Man05]) if it is quasiisometric to a simplicial tree. According to [Man05], $Y$ is a quasi-tree if and only if there exists a constant $r$ such that for every geodesic segment $x y \subset Y$, the (closed) ball $B(m, r)$ centered at the midpoint $m$ of $x y$ separates $x$ and $y$. (Here and below, separation is understood in the sense that every path connecting $x$ and $y$ has to pass through $B(z, r)$.) Alternatively, one characterizes quasi-trees by the existence of $r$ such that for every geodesic segment $x y \subset Y$ and every $z \in x y$, the ball $B(z, r)$ separates $x$ and $y$.

Lemma 3.43. Suppose that $p$ is a point ${ }^{2}$ in an interval $J=\llbracket u, v \rrbracket \subset T$. Then:

1. The closed unit ball $B_{\Gamma}(p, 1) \subset \Gamma$ separates $u$ and $v$.
2. $d_{\Gamma}(u, v) \geq d_{\Gamma}(u, w)$.

Proof. Both parts of the lemma are proven by the same argument. Suppose that $w_{0}=$ $u, w_{1}, \ldots, w_{n}, w_{n+1}=v$ is a vertex-path in $\Gamma$ connecting $u$ to $v$. Since $p$ separates $u$ from $v$, there exists $i \leq n$ such that $w_{i}, w_{i+1}$ are separated by $p$ in $T$ and, of course, $d_{\Gamma}\left(w_{i}, w_{i+1}\right)=1$. Lemma 3.40 implies that

$$
d_{\Gamma}\left(w_{i}, p\right) \leq 1, d_{\Gamma}\left(w_{i+1}, p\right) \leq 1
$$

[^9]This proves Part (1) of the lemma. To prove Part (2) we take the above vertex-path to be geodesic in $\Gamma$ and observe that

$$
d_{\Gamma}(p, u) \leq d_{\Gamma}\left(p, w_{i}\right)+d_{\Gamma}\left(w_{i}, u\right) \leq 1+d_{\Gamma}\left(u, w_{i}\right) \leq d_{\Gamma}(u, v)
$$

Lemma 3.43 thus implies that for every $K$ and a tree of hyperbolic spaces spaces $\mathfrak{X}$, the graph $\Gamma=\Gamma_{K}$ is a quasi-tree with the constant $r=1$.

We are now ready to prove the horizontal subdivision lemma, which will play an important role in Chapter 6, when we establish uniform hyperbolicity of $K$-flows of intervalspaces $X_{J}$ in $\mathfrak{X}$.

Figure 5. Horizontal subdivision

Lemma 3.44 (Horizontal subdivision lemma). For any pair of distinct vertices $u, v \in T$, the interval $J=\llbracket u, v \rrbracket$, can be subdivided into nondegenerate subintervals

$$
J=\llbracket u_{0}, u_{1} \rrbracket \cup \ldots \cup \llbracket u_{n-1}, u_{n} \rrbracket \cup \llbracket u_{n}, u_{n+1} \rrbracket, \quad u=u_{0}, v=u_{n+1},
$$

and each $J_{i}=\llbracket u_{i}, u_{i+1} \rrbracket$ can be further subdivided into subintervals (some of which could be degenerate),

$$
\llbracket u_{i}, u_{i}^{\prime \prime} \rrbracket \cup \llbracket u_{i}^{\prime \prime}, u_{i+1}^{\prime} \rrbracket \cup \llbracket u_{i+1}^{\prime}, u_{i+1} \rrbracket,
$$

so that the following hold for all $i \leq n$ :
(1)

$$
\pi\left(F l_{K}\left(X_{u_{i}}\right)\right) \cap J_{i}=\llbracket u_{i}, u_{i}^{\prime \prime} \rrbracket,
$$

(i.e. the interval $\llbracket u_{i}, u_{i}^{\prime \prime} \rrbracket$ is special) and

$$
u_{i}^{\prime \prime} \notin \pi\left(F l_{K}\left(X_{u_{i+1}}\right)\right),
$$

unless $i=n$ in which case we could have $u_{i}^{\prime \prime} \in \pi\left(F l_{K}\left(X_{u_{i+1}}\right)\right)$.
(2) The interval $\llbracket u_{i}^{\prime \prime}, u_{i+1}^{\prime} \rrbracket$ is special, it is contained in $\pi\left(F l_{K}\left(X_{u_{i+1}^{\prime}}\right)\right)$.
(3) The interval $\llbracket u_{i}^{\prime \prime}, u_{i+1}^{\prime} \rrbracket$ is nondegenerate unless $i=n$.
(4) $d_{T}\left(u_{i+1}^{\prime}, u_{i+1}\right) \leq 1$, thus, each interval $\llbracket u_{i+1}^{\prime}, u_{i+1} \rrbracket$ is special.

Proof. We find the subdivision vertices inductively. Set $u_{0}:=u$. Inductively, we assume that $u_{i}$ is defined. If $u_{i}=v$, we set $n+1=i$ and terminate the induction. Suppose, therefore, that this is not the case. We then define $u_{i}^{\prime \prime}, u_{i+1}^{\prime}$ and $u_{i+1}$ :

We choose a vertex $u_{i}^{\prime \prime} \in \rrbracket u_{i}, v \rrbracket$ to be the farthest from $u_{i}$ such that

$$
F l_{K}\left(X_{u_{i}}\right) \cap X_{u_{i}^{\prime \prime}} \neq \emptyset .
$$

Note that such a vertex always exists since for the edge $\left[u_{i}, v_{i}\right] \in E\left(\llbracket u_{i}, v \rrbracket\right)$ we have

$$
F l_{K}\left(X_{u_{i}}\right) \cap X_{v_{i}} \neq \emptyset .
$$

If it so happens that $u_{i}^{\prime \prime}=v$, we set $n=i$, and $u_{i+1}^{\prime}:=u_{i+1}=v$; this will conclude the induction. Suppose that this is not the case.

Then consider the vertices $s \in \rrbracket u_{i}^{\prime \prime}, v \rrbracket$ such that

$$
F l_{K}\left(X_{s}\right) \cap X_{u_{i}^{\prime \prime}}=\emptyset .
$$

If such a vertex does not exist, then we set $n=i, u_{i+1}^{\prime}=u_{i}^{\prime \prime}$ and $u_{i+1}=v$, and again conclude the subdivision process. Assume that this is not the case. Then we define $u_{i+1} \in \rrbracket u_{i}^{\prime \prime}, v \rrbracket$ to be the closest vertex to $u_{i}^{\prime \prime}$ such that $F l_{K}\left(X_{u_{i+1}}\right) \cap X_{u_{i}^{\prime \prime}}=\emptyset$. We define $u_{i+1}^{\prime}$ in this case to be the vertex in $J_{i}=\llbracket u_{i}, u_{i+1} \rrbracket$ adjacent to $u_{i+1}$, i.e. $d_{T}\left(u_{i+1}^{\prime}, u_{i+1}\right)=1$. Then, by the definition of $u_{i+1}$,

$$
F l_{K}\left(u_{i+1}^{\prime}\right) \cap X_{u_{i}^{\prime \prime}} \neq \emptyset
$$

Hence, the vertices $u_{i}^{\prime \prime}, u_{i+1}^{\prime}, u_{i+1}$ satisfies requirements of the lemma and we continue inductively.

Corollary 3.45. 1. Each interval $J_{i}$ as above is the union of (at most) three special intervals and the sequence

$$
\ldots u_{i}, u_{i+1}^{\prime}, u_{i+1}, \ldots
$$

is a vertex-path in $\Gamma$.
2. For any two consecutive vertices $u_{i}, u_{i+1}, i \leq n-1$,

$$
d_{\Gamma}\left(u_{i}, u_{i+1}\right)=2,
$$

while $1 \leq d_{\Gamma}\left(u_{n}, u_{n+1}\right) \leq 2$.
3. For each pair of indices $i, j$, if $0 \leq i+1<j \neq n$, then

$$
d_{\Gamma}\left(u_{i}, u_{j}\right) \geq 2
$$

In particular, if $|i-j| \geq 2$, the flow-spaces $F l_{K}\left(X_{J_{i}}\right), F l_{K}\left(X_{J_{j}}\right)$ are $L_{3.21}(K)$-Lipschitz cobounded in $X$.

### 3.4. Retractions to bundles

The main goal of this section is to prove Theorem 3.49, which is an analogue of Theorem 3.21, constructing coarse Lipschitz retractions from flow-spaces to certain $K^{\prime}$ metric bundles $\mathfrak{Y})=(\pi: Y \rightarrow S) \subset \mathfrak{X}$ with $\lambda$-quasiconvex fibers $Y_{v} \subset X_{v}$. In Theorem 3.49 we will impose a stronger assumption on $\mathfrak{X}$, namely the $\kappa$-uniform flaring condition for a certain constant $\kappa \geq K$ (see (3.19) for the definition of this constant, which depends on $K, K^{\prime}$, on a quasiconvexity constant $\lambda$ of $Y_{v} \subset X_{v}$, and on a constant $D$ which is an upper bound on the diameter of $Y_{w}$ for some $w \in V(S)$ ), that was not needed in Theorem 3.21. While the $\kappa$-flaring condition implies $k$-flaring for all $k \in[1, \kappa]$, it will be notationally convenient to also have the constants $M_{k}, k \leq \kappa$, at our disposal, hence, we will be assuming the uniform $k$-flaring condition for all $k \in[1, \kappa]$.

The retractions $\rho_{\mathfrak{9}}: F l_{K}\left(Q_{u}\right) \rightarrow Y$ will be defined on flow-spaces $F l_{K}\left(Q_{u}\right)$ whose $4 \delta_{0}$-fiberwise neighborhoods contain $Y$, but composing $\rho_{9)}$ with Mitra's retraction $\rho: X \rightarrow$ $F l_{K}\left(Q_{u}\right)$, we then obtain retractions defined on the entire $X$. In the special case, when $F l_{K}\left(Q_{u}\right)$ is $\delta$-hyperbolic, the retraction $\rho_{\mathfrak{9}}$ will be uniformly close to the nearest-point projection $F l_{K}\left(Q_{u}\right) \supset Y$ (see Proposition 3.62).

Remark 3.46. 1. The condition that $\rho_{\mathfrak{Y})}$ is a retraction should be understood coarsely since $Y$ is not quite contained in $F l_{K}\left(Q_{u}\right)$ : We can only guarantee that $\rho_{\mathfrak{Y}}$ fixes all points in $\mathcal{Y} \cap \mathcal{F} l_{K}\left(Q_{u}\right)$; the rest of the points of $F l_{K}\left(Q_{u}\right)$ lie in the $\max \left(K, 4 \delta_{0}\right)$-neighborhood of $Y$ and $\rho_{\mathfrak{9}}$ can move them only by a uniformly bounded amount.
2. In the case when $\mathfrak{Y}$ is a $K^{\prime}$-carpet, which is of the main interest, $\lambda=\delta_{0}$.

Lemma 3.47. Fix $\lambda$ and $K^{\prime}$. Suppose that a subtree of spaces $\mathfrak{Y} \subset \mathfrak{X}$ is a $K^{\prime}$-metric bundle over a subtree $S=\pi(Y) \subset T$. Assume also that vertex-spaces $Y_{v}=Y \cap X_{v}, v \in$ $V(S)$, are $\lambda$-quasiconvex in $X_{v}$. Then the fiberwise nearest-point projection $X_{S} \rightarrow Y$ is a $D_{3.47}\left(\lambda, K^{\prime}\right)$-coarse Lipschitz retraction. In particular, if $\gamma$ is a $C$-qi section over some interval $J \subset S$, then the fiberwise projection $\bar{\gamma}$ of $\gamma$ to $Y$ is a $K_{3.47}\left(\lambda, K^{\prime}, C\right)=C D_{3.47}\left(\lambda, K^{\prime}\right)$ qi section over J, where

$$
K_{3.47}\left(\lambda, K^{\prime}, C\right) \geq \max \left(C, K^{\prime}\right)
$$

Proof. The lemma is an immediate corollary of Corollary 2.23.
Notation 3.48. 1. For the rest of this subsection we will use the notation $\bar{K}$ for $K_{3.47}\left(\lambda, K^{\prime}, K\right)$. We also set $\overline{\bar{K}}:=K_{3.47}\left(\delta_{0}, K_{3.17}^{\prime}(K), \bar{K}\right)$. Note that

$$
\overline{\bar{K}} \geq \max \left(\bar{K}, K_{3.17}^{\prime}(K)\right)
$$

In these notation we suppress the dependence on $\lambda$ and $K^{\prime}$ : In the most useful for us case, when $\mathfrak{Y}$ ) is a $K$-carpet, we will have $\lambda=\delta_{0}$.
2. Define

$$
\begin{gather*}
r:=r_{3.17}=3 \delta_{0}+\lambda+R_{2.49}(\overline{\bar{K}}, 1)+R_{2.49}\left(\bar{K}, M_{\bar{K}}\right)  \tag{3.17}\\
k=K^{\prime}+R_{2.49}(\bar{K}, r)  \tag{3.18}\\
\kappa:=\kappa_{3.19}\left(\lambda, K, K^{\prime}\right):=\max (k, \overline{\bar{K}}) \tag{3.19}
\end{gather*}
$$

Observe that $\kappa \geq \overline{\bar{K}} \geq \bar{K} \geq K$. The proof of the following theorem will need uniform $\overline{\bar{K}}$-flaring (in numerous places) as well as the uniform $\left(K^{\prime}+R_{2.49}\left(\bar{K}, r_{i}\right)\right.$ )-flaring for some numbers $r_{1}, r_{2}, r_{3}$ (subcases (i), (ii) and (iii) respectively in the proof of Proposition 3.51); the constant $r$ above is chosen to be the maximum of the numbers $r_{1}, r_{2}, r_{3}$.

Theorem 3.49. Fix constants $K, K^{\prime}$ and $\lambda$ and assume that, $\mathfrak{Y}=(\pi: Y \rightarrow S) \subset \mathfrak{X}$ is $a$ $K^{\prime}$-metric bundle with $\lambda$-quasiconvex fibers. We assume, furthermore, that

1. There exists a vertex $w \in S$ such that $\operatorname{diam}_{X_{w}}\left(Y_{w}\right) \leq D^{\prime}$.
2. The tree of spaces $\mathfrak{X}$ satisfies the uniform flaring condition for all parameters in the interval $[1, \kappa]$, in particular, for $\bar{K}, K^{\prime}$ and $\overline{\bar{K}}$; see (3.19) for the definition of $\kappa$ which depends on $K, K^{\prime}$ and $\lambda$.
3. We assume that $\mathfrak{Y}$ ) is either a $\left(K^{\prime}, D^{\prime}\right)$-carpet $\mathfrak{H}\left(\alpha^{\prime}\right)$ contained in a $K$-ladder ${ }^{3} 3=$ $\mathfrak{L}_{K}(\alpha)$,

$$
\alpha^{\prime} \subset \alpha \subset X_{u}, \text { length }\left(\alpha^{\prime}\right) \geq \text { length }(\alpha)-M_{\bar{K}},
$$

or $\mathfrak{Y}$ is a general $K^{\prime}$-metric bundle contained in the fiberwise $4 \delta_{0}^{\prime}$-neighborhood of a $K$ -flow-space $3=\mathfrak{F} l_{K}\left(Q_{u}\right)$, such that $Y_{u}=Q_{u}$.

In both cases, we let $Z$ denote the total space of 3 and $\mathcal{Z}:=Z \cap \mathcal{X}$.
Then there exists a coarse $L_{3.49}\left(\lambda, K, K^{\prime}, D^{\prime}\right)$-Lipschitz retraction

$$
\rho=\rho_{Y}: \mathcal{Z} \rightarrow \boldsymbol{y}
$$

Proof. The proof of this theorem is quite long and technical; it occupies most of the rest of this section.

Step 1: Construction of the $\operatorname{map} \rho: \mathcal{Z} \rightarrow \mathcal{Y}$.
For each $x \in \mathcal{Z}$ with $v=\pi(x) \in V(T)$, we fix a $K$-qi section $\gamma_{x}$ of $\pi: Z \rightarrow \pi(Z) \subset T$ over $\llbracket u, v \rrbracket$, connecting $x$ to some point in $Z_{u}$ once and for all.

Let $b=b_{x}$ be the nearest point projection of $v$ to $S$ in $T$. We define the following important points:

[^10]- We let $t=t_{x} \in \llbracket u, b \rrbracket$ be the vertex farthest from $u$ such that there exists a point $\tilde{x} \in \gamma_{x}(t)$ for which

$$
d_{X_{t}}\left(\tilde{x}, Y_{t}\right) \leq M_{\bar{K}}
$$

(Note that it is possible that $t=u$ and $\tilde{x} \in Z_{u}$.)

- Let $\bar{x} \in Y_{t}$ be a nearest-point projection to $\tilde{x}$ to $Y_{t}$ in the vertex space $X_{t}$.

Thus,

$$
\begin{equation*}
d_{X_{t_{x}}}(\tilde{x}, \bar{x}) \leq M_{\bar{K}} \tag{3.20}
\end{equation*}
$$

and if $x \in Y_{v}$, then $t_{x}=v$ and $\bar{x}=\tilde{x}=x$.

Figure 6. Projection to a bundle which is a carpet

Definition 3.50. 1. We define the retraction $\rho=\rho_{\mathfrak{y}}: \mathcal{Z} \rightarrow \mathcal{Y}$ by $\rho(x):=\bar{x}$. We extend this map to $Z$ using the fact that $\mathcal{Z}$ is a $K$-net in $Z$ (to define the extension we compose a nearest-point projection with $\rho$ ). See Figure 6.
2. We define a path $c_{x}=c_{x, Y}$ connecting $x$ to $\rho(x) \in Y$ as the concatenation

$$
\gamma_{x, \tilde{x}} \star[\tilde{x} \bar{x}]_{X_{t}},
$$

where $t=t_{x}$, and

$$
\gamma_{x, \tilde{x}}=\left.\gamma_{x}\right|_{\llbracket v, t \rrbracket},
$$

is the subpath of $\gamma_{x}$ connecting $x$ to $\tilde{x}$. We will refer to the latter as the horizontal part of $c_{x}$. The vertical part of $c_{x}$ is the geodesic $[\tilde{x} \bar{x}]_{X_{t}}$; it is a path of uniformly bounded length (see (3.20)) connecting $\tilde{x}$ to $\bar{x}$ and contained in the $4 \delta_{0}$-neighborhood of $Z_{t}=Z \cap X_{t}$.

Step 2: Verification of the properties of $\rho$. It suffices to verify the coarse Lipschitz property for the restriction of $\rho$ to $\mathcal{Z}$. We note further that it is enough to get a uniform upper bound on $d(\rho(x), \rho(y))$ for two types of pairs $(x, y)$ :
a. $x, y \in Z_{v}, d_{X_{v}}(x, y) \leq 1$.
b. The vertices $v_{1}=\pi(x), v_{2}=\pi(y)$ span an edge in $T$ and $d_{X_{v_{1} v_{2}}}(x, y) \leq K$.

These two cases are treated in Proposition 3.51 and Lemma 3.58 respectively. The former is the longest and hardest part of the proof.

For the following proposition we observe that, according to the 3rd assumption of Theorem 3.49, $\mathfrak{X}$ satisfies the uniform $k$-flaring condition for

$$
k=K^{\prime}+R_{2.49}(\bar{K}, r),
$$

where

$$
r=\max \left(M_{\bar{K}}, 6 \delta_{0}+\lambda+R_{2.49}(\overline{\bar{K}}, 1), 3 \delta_{0}+\lambda+R_{2.49}(\overline{\bar{K}}, 1)+R_{2.49}\left(\bar{K}, M_{\bar{K}}\right)\right)
$$

where

$$
r=3 \delta_{0}+\lambda+R_{2.49}(\overline{\bar{K}}, 1)+R_{2.49}\left(\bar{K}, M_{\bar{K}}\right)
$$

since $R_{2.49}\left(\bar{K}, M_{\bar{K}}\right) \geq \max \left(3 \delta_{0}, M_{\bar{K}}\right)$.
Proposition 3.51. Suppose that $x, y \in \mathcal{Z} \cap X_{v}$. If $x$, $y$ are within distance 1 from each other in $X_{v}$, then $d_{X}(\rho(x), \rho(y)) \leq C_{3.51}\left(\lambda, K, K^{\prime}, D^{\prime}\right)$. The bound is independent of the choice of the paths $\gamma_{x}, \gamma_{y}$ as above.

The proof of this proposition is long and is done through analyzing several cases and subcases. We use the notation preceding Definition 3.50 and note that in the setting of the proposition, $b_{x}=b_{y}$; we will denote this vertex simply by $b$.

Now we define certain auxiliary objects and make general remarks to be used in the proof, especially in Cases 2 and 3 below. We let $z$ denote the nearest point projection (in $T)$ of $b$ to $\llbracket u, w \rrbracket$, i.e. $z$ is the center of the triangle $\Delta u w b$.

Remark 3.52. (1) For each vertex $s \in T$, every geodesic $\alpha \subset X_{s}$ is $\delta_{0}$-quasiconvex in $X_{s}$. Hence, the nearest-point projection (in $X_{s}$ ) to $\alpha$ is coarsely $L_{1.99}\left(\delta_{0}, \delta_{0}\right)$ Lipschitz.
(2) We let $\bar{\gamma}_{x}$ and $\bar{\gamma}_{y}$ denote the fiberwise projections (to $Y$ ) of the restrictions to $\llbracket b, u \rrbracket$ of $\gamma_{x}$ and $\gamma_{y}$ respectively. These are $\bar{K}$-qi sections over $\llbracket b, u \rrbracket$. (See Lemma 3.47 and Notation 3.48.) Then, by the definition of $t_{x}, t_{y}$,

$$
\begin{gathered}
d_{X_{s}}\left(\gamma_{x}(s), \bar{\gamma}_{x}(s)\right)>M_{\bar{K}}, \forall s \in V\left(\rrbracket t_{x}, b \rrbracket\right), d_{X_{t_{x}}}\left(\gamma_{x}\left(t_{x}\right), \bar{\gamma}_{x}\left(t_{x}\right)\right) \leq M_{\bar{K}} \\
d_{X_{s}}\left(\gamma_{y}(s), \bar{\gamma}_{y}(s)\right)>M_{\bar{K}}, \forall s \in V\left(\rrbracket t_{y}, b \rrbracket\right) d_{X_{t y}}\left(\gamma_{y}\left(t_{y}\right), \bar{\gamma}_{y}\left(t_{y}\right)\right) \leq M_{\bar{K}} .
\end{gathered}
$$

(3) Since $\bar{K} \geq K$ and $\gamma_{x}(u)=\bar{\gamma}_{x}(u)$, by Corollary 2.49 we have

$$
d_{X_{s}}\left(\gamma_{x}(s), \bar{\gamma}_{x}(s)\right) \leq R_{2.49}\left(\bar{K}, M_{\bar{K}}\right)
$$

for all $s \in V\left(\llbracket t_{x}, u \rrbracket\right)$ and, similarly,

$$
d_{X_{s}}\left(\gamma_{y}(s), \bar{\gamma}_{y}(s)\right) \leq R_{2.49}\left(\bar{K}, M_{\bar{K}}\right), \quad \forall s \in V\left(\llbracket t_{y}, u \rrbracket\right)
$$

(4) The carpet $\mathfrak{A}$ bounded by $\gamma_{x}$ and $\gamma_{y}$ (with the narrow end $\left[\gamma_{x}(v) \gamma_{y}(v)\right]_{X_{v}}$ ) is a $K_{3.17}^{\prime}(K)$-carpet over $\llbracket u, v \rrbracket$; in particular, it is a $K_{3.17}^{\prime}(K)$-metric bundle whose fibers are $\delta_{0}$-quasiconvex in the corresponding vertex spaces. We let $\overline{\bar{\gamma}}_{x}$ and $\overline{\bar{\gamma}}_{y}$ denote, respectively, the fiberwise projections of $\bar{\gamma}_{x}$ and $\bar{\gamma}_{y}$ to $\mathfrak{A}$. Thus, by Lemma 3.47 , both $\overline{\bar{\gamma}}_{x}$ and $\overline{\bar{\gamma}}_{y}$ are $\overline{\bar{K}}=K_{3.47}\left(\delta_{0}, K_{3.17}^{\prime}(K), \bar{K}\right)$-qi sections over $\llbracket u, b \rrbracket$.
(5) Since $\mathfrak{A}$ is a $K_{3.17}^{\prime}(K)$-carpet, we can join the points $\overline{\bar{\gamma}}_{x}(b)$ and $\overline{\bar{\gamma}}_{y}(b)$ to some points of $[x y]_{X_{v}}$ in $\mathfrak{A}$ via $K_{3.17}^{\prime}(K)$-qi sections over $\llbracket v, b \rrbracket$. Since $\overline{\bar{K}} \geq K_{3.17}^{\prime}(K)$, the concatenation of these qi sections with sections $\overline{\bar{\gamma}}_{x}$ and $\overline{\bar{\gamma}}_{y}$ (over $\llbracket u, b \rrbracket$ ) are both $\overline{\bar{K}}$-qi sections over $\llbracket u, v \rrbracket$, joining $\gamma_{x}(u)$ and $\gamma_{y}(u)$ to some points of $[x y]_{X_{v}}$. We retain the notation $\overline{\bar{\gamma}}_{x}$ and $\overline{\bar{\gamma}}_{y}$ for these concatenations.
(6) Notice that $\overline{\bar{\gamma}}_{x}(u)=\bar{\gamma}_{x}(u)=\gamma_{x}(u)$ and $\overline{\bar{\gamma}}_{y}(u)=\bar{\gamma}_{y}(u)=\gamma_{y}(u)$. At the same time, the other pair of end-points (namely, points in $[x y]_{X_{v}}$ ) of $\gamma_{x}$ and $\overline{\bar{\gamma}}_{x}$, respectively, of $\gamma_{y}$ and $\overline{\bar{\gamma}}_{y}$, are within distance $\leq 1$ in $X_{\nu}$. Therefore, by Corollary 2.49, we have

$$
d_{X_{s}}\left(\gamma_{x}(s), \overline{\bar{\gamma}}_{x}(s)\right) \leq R_{2.49}(\overline{\bar{K}}, 1), \forall s \in V(\llbracket v, u \rrbracket)
$$

and

$$
d_{X_{s}}\left(\gamma_{y}(s), \overline{\bar{\gamma}}_{y}(s)\right) \leq R_{2.49}(\overline{\bar{K}}, 1), \forall s \in V(\llbracket v, u \rrbracket)
$$

Figure 7. Projections $\bar{\gamma}_{x}, \bar{\gamma}_{y}, \overline{\bar{\gamma}}_{x}, \overline{\bar{\gamma}}_{y}$.

Before proving the proposition we will need a technical lemma:
Lemma 3.53. Suppose that $r$ is such that $\mathfrak{X}$ satisfies the uniform $k$-flaring condition with

$$
k=k_{3.53}=K^{\prime}+R_{2.49}(\bar{K}, r) .
$$

Then the following holds.
Suppose that there are vertices $v_{1} \in \llbracket t_{x}, b \rrbracket \cap \llbracket z, b \rrbracket$ and $v_{2} \in \llbracket t_{y}, b \rrbracket \cap \llbracket z, b \rrbracket$ such that

$$
\begin{equation*}
d_{X_{v_{1}}}\left(\gamma_{x}\left(v_{1}\right), \bar{\gamma}_{x}\left(v_{1}\right)\right) \leq r \text { and } d_{X_{v_{2}}}\left(\gamma_{y}\left(v_{2}\right), \bar{\gamma}_{y}\left(v_{2}\right)\right) \leq r \tag{3.21}
\end{equation*}
$$

Then:
(i) $d_{T}\left(v_{1}, v_{2}\right) \leq \tau_{3.53}=\tau_{3.53}\left(K, r, D^{\prime}\right)$.
(ii) $d\left(\gamma_{x}\left(v_{1}\right), \gamma_{y}\left(v_{2}\right)\right) \leq R_{3.53}=R_{3.53}\left(K, r, D^{\prime}\right)$.
(iii)

$$
d_{X_{s}}\left(\gamma_{x}(s), \gamma_{y}(s)\right) \leq R_{2.49}\left(k, \max \left(1, D^{\prime}\right)\right), \forall s \in \llbracket v, z \rrbracket .
$$

Proof. (i) Taking into account the fact that $K \leq \bar{K} \leq \kappa, \gamma_{x}(u)=\bar{\gamma}_{x}(u), \gamma_{y}(u)=\bar{\gamma}_{y}(u)$, as well as the inequalities (3.21), we see that Corollary 2.49 applied to $\gamma_{x} \|_{\llbracket u, v_{1} \rrbracket}$ and $\bar{\gamma}_{y} \|_{\llbracket u, v_{2} \rrbracket}$ and the vertex $z \in \llbracket u, v_{1} \rrbracket \cap \llbracket u, v_{2} \rrbracket$, implies that

$$
d_{X_{z}}\left(\gamma_{x}(z), \bar{\gamma}_{x}(z)\right) \leq R_{2.49}(\bar{K}, r)
$$

and

$$
d_{X_{z}}\left(\gamma_{y}(z), \bar{\gamma}_{y}(z)\right) \leq R_{2.49}(\bar{K}, r)
$$

We join $\bar{\gamma}_{x}(z)$ and $\bar{\gamma}_{y}(z)$ to $Y_{w}$ by two $K^{\prime}$-qi sections over $\llbracket z, w \rrbracket$ contained in $Y, \gamma_{x, 1}$ and $\gamma_{y, 1}$ respectively.

We let $z_{1}$ denote the vertex in $\llbracket z, w \rrbracket$ adjacent to $z$, assuming that $z \neq w$. We connect $\gamma_{x}(z)$ and $\gamma_{x, 1}\left(z_{1}\right)$ by a geodesic path $\gamma_{1, z, z_{1}}$ in $X_{z z_{1}}$, similarly, connect $\gamma_{y}(z)$ and $\gamma_{y, 1}\left(z_{1}\right)$ by a geodesic path $\gamma_{2, z, z 1}$ in $X_{z z_{1}}$. Both paths have length $\leq k=K^{\prime}+R_{2.49}(\bar{K}, r)$.

Then we get that the concatenations

$$
\gamma_{x}^{\prime}:=\left.\left.\gamma_{x}\right|_{\llbracket v, z \rrbracket} \star \gamma_{1, z, z_{1}} \star \gamma_{x, 1}\right|_{\llbracket z_{1}, w \rrbracket}
$$

and

$$
\gamma_{y}^{\prime}:=\gamma_{y} \|\left._{\llbracket v, z \mathbb{\|}} \star \gamma_{2, z, z_{1}} \star \gamma_{y, 1}\right|_{\llbracket z_{1}, w \rrbracket} .
$$

These are $k$-qi sections over $\llbracket v, w \rrbracket$. (See the bold paths in Figure 8.) Their end-points are at a distance at most $\max \left(1, D^{\prime}\right)$ of the respective vertex-spaces (since $d_{X_{v}}(x, y) \leq 1$ and $Y_{w}$ has diameter $\leq D^{\prime}$ ).

Hence (since $\mathfrak{X}$ is assumed to satisfy the uniform $k$-flaring condition), by Corollary 2.49,

$$
d_{X_{s}}\left(\gamma_{x}^{\prime}(s), \gamma_{y}^{\prime}(s)\right) \leq R_{2.49}\left(k, \max \left(1, D^{\prime}\right)\right), \forall s \in \llbracket v, w \rrbracket
$$

and, restricting to the subinterval $\llbracket v, z \rrbracket$, we obtain

$$
\begin{equation*}
d_{X_{s}}\left(\gamma_{x}(s), \gamma_{y}(s)\right) \leq R_{2.49}\left(k, \max \left(1, D^{\prime}\right)\right), \forall s \in \llbracket v, z \rrbracket \tag{3.22}
\end{equation*}
$$

In the case $z=w$, we will use the paths

$$
\gamma_{x}^{\prime}:=\left.\gamma_{x}\right|_{\llbracket v, z \mathbb{\|}}, \gamma_{y}^{\prime}:=\left.\gamma_{y}\right|_{\llbracket v, z \mathbb{\|}}
$$

and obtain the same inequality (3.22).
Thus, we established Part (iii) of the lemma.
Since the fiberwise projection to $Y_{s}, s \in \llbracket b, z \rrbracket$ is $L_{1.99}\left(\delta_{0}, \lambda\right)$-Lipschitz, we get

$$
\begin{equation*}
d_{X_{s}}\left(\bar{\gamma}_{x}(s), \bar{\gamma}_{y}(s)\right) \leq L_{1.99}\left(\delta_{0}, \lambda\right)\left(R_{2.49}\left(k, \max \left(1, D^{\prime}\right)\right)+1\right), \forall s \in \llbracket b, z \rrbracket . \tag{3.23}
\end{equation*}
$$

Without loss of generality (by switching the roles of $x$ and $y$ if necessary), we may assume that $v_{2}$ is a vertex in $\llbracket v_{1}, b \rrbracket$.

Combining the second inequality in (3.21) with the inequalities (3.22), (3.23) applied to $s=v_{2}$, by the triangle inequality in $X_{v_{2}}$ we obtain:

$$
\begin{array}{r}
d_{X_{v_{2}}}\left(\gamma_{x}\left(v_{2}\right), \bar{\gamma}_{x}\left(v_{2}\right)\right) \leq \\
R_{1}:=r+R_{2.49}\left(k, \max \left(1, D^{\prime}\right)\right)+L_{1.99}\left(\delta_{0}, \lambda\right)\left(R_{2.49}\left(k, \max \left(1, D^{\prime}\right)\right)+1\right) . \tag{3.24}
\end{array}
$$

Hence, by taking into account the fact that

$$
d_{X_{s}}\left(\gamma_{x}(s), \bar{\gamma}_{x}(s)\right)>M_{\bar{K}}
$$

for all vertices $s$ of $\rrbracket t_{x}, b \rrbracket$ (and the reverse inequality at $t_{x}$ and the inequality (3.24)) and using the $\bar{K}$-uniform flaring property of the sections $\gamma_{x}, \bar{\gamma}_{x}$ over the interval $\llbracket t_{x}, v_{2} \rrbracket$, we obtain

$$
d_{T}\left(v_{1}, v_{2}\right) \leq d_{T}\left(t_{x}, v_{1}\right) \leq \tau_{3.53}\left(K, r, D^{\prime}\right):=\tau_{2.43}\left(\bar{K}, R_{1}\right)
$$

This concludes the proof of Part (i).
(i) $\Rightarrow$ (ii): $d\left(\gamma_{x}\left(v_{1}\right), \gamma_{y}\left(v_{2}\right)\right)$ is bounded by the length of the concatenation of the paths $\left.\gamma_{x}\right|_{\llbracket v_{1}, v_{2} \rrbracket}$ (whose length is estimated by (i)) and $\left[\gamma_{x}\left(v_{2}\right) \gamma_{y}\left(v_{2}\right)\right]_{X_{v_{2}}}$ (whose length is estimated by (3.22) since $\left.v_{2} \in \llbracket b, z \rrbracket\right)$ is which therefore at most

$$
R_{3.53}\left(K, r, D^{\prime}\right):=K \cdot \tau_{3.53}\left(K, r, D^{\prime}\right)+R_{2.49}\left(k, \max \left(1, D^{\prime}\right)\right)
$$

We will be using this lemma in the proof of Proposition 3.51 with $r=r_{1}, r=r_{2}, r=r_{3}$ (defined below), where $r_{2}$ is the largest of the three parameters. The uniform flaring condition made in the statement of the Proposition ensures that the uniform $k$-flaring condition in the lemma is satisfied for $r=r_{2}$ and, hence, for the two other (smaller) values of $r$.

Proof of Proposition 3.51. There are several cases to consider depending on mutual position of various vertices in $T$.

Case 1: Suppose $v \in V(\llbracket u, w \rrbracket)$, in which case $b=v$. Without loss of generality we may assume that $t_{y} \in V\left(\llbracket t_{x}, v \rrbracket\right)$.

Consider the subset

$$
W=\left\{s \in V\left(\llbracket t_{y}, v \rrbracket\right): d_{X_{s}}\left(\bar{\gamma}_{x}(s), \bar{\gamma}_{y}(s)\right) \geq D_{1.120}^{\prime}\left(\delta_{0}, \delta_{0}\right)\right\} .
$$

If $W \neq \emptyset$, let $v_{1}$ be the farthest vertex from $t_{y}$ in $W$. If $W=\emptyset$ then define $v_{1}$ to be $t_{y}$. In other words, $v_{1}=\sup W$ in the (oriented) interval $\llbracket t_{y}, v \rrbracket$.

Figure 8. Illustration of the proof of Lemma 3.53

## Claim 3.54. All three distances

$$
d_{X_{v_{1}}}\left(\gamma_{x}\left(v_{1}\right), \gamma_{y}\left(v_{1}\right)\right), d_{X_{v_{1}}}\left(\gamma_{x}\left(v_{1}\right), \bar{\gamma}_{x}\left(v_{1}\right)\right), d_{X_{v_{1}}}\left(\gamma_{y}\left(v_{1}\right), \bar{\gamma}_{y}\left(v_{1}\right)\right)
$$

are bounded above by

$$
\begin{array}{r}
C_{3.54}=2 R_{2.49}(\overline{\bar{K}}, 1)+ \\
\max \left(M_{\bar{K}}+\delta_{0}\left(21+72 \delta_{0}\right), 9 \delta_{0}\left(1+D_{2.39}\left(\bar{K}, 9 \delta_{0}\right)\right)\right)
\end{array}
$$

See bold curves in Figure 9.
Proof. The proof is divided into two subcases.
Subcase (i): Suppose that $W=\emptyset$, thus, $v_{1}=t_{y} \in \llbracket u, v \rrbracket$. In this case

$$
d_{X_{v_{1}}}\left(\bar{\gamma}_{x}\left(v_{1}\right), \bar{\gamma}_{y}\left(v_{1}\right)\right)<D_{1.120}\left(\delta_{0}, \delta_{0}\right)
$$

By Remark 3.52(1),

$$
\left.d_{X_{v_{1}}}\left(\overline{\bar{\gamma}}_{x}\left(v_{1}\right)\right), \overline{\bar{\gamma}}_{y}\left(v_{1}\right)\right) \leq L_{1.99}\left(\delta_{0}, \delta_{0}\right)\left(1+D_{1.120}\left(\delta_{0}, \delta_{0}\right)\right)
$$

By combining this inequality with the two inequalities in Remark 3.52(6), we obtain (by the triangle inequality in $X_{v_{1}}$ )

$$
\begin{array}{r}
d_{X_{v_{1}}}\left(\gamma_{x}\left(v_{1}\right), \gamma_{y}\left(v_{1}\right)\right) \leq 2 R_{2.49}(\overline{\bar{K}}, 1)+L_{1.99}\left(\delta_{0}, \delta_{0}\right)\left(1+D_{1.120}\left(\delta_{0}, \delta_{0}\right)\right)=  \tag{3.25}\\
2 R_{2.49}(\overline{\bar{K}}, 1)+12 \delta_{0}\left(1+9 \delta_{0}\right),
\end{array}
$$

c.f. Remark 1.100 and Lemma 1.120(2).

Since $v_{1}=t_{y}$,

$$
\begin{equation*}
d_{X_{v_{1}}}\left(\gamma_{y}\left(v_{1}\right), \bar{\gamma}_{y}\left(v_{1}\right)\right) \leq M_{\bar{K}} \tag{3.26}
\end{equation*}
$$

and it follows from the triangle inequality applied to the quadrilateral in $X_{v_{1}}$ with the vertices

$$
\gamma_{x}\left(v_{1}\right), \gamma_{y}\left(v_{1}\right), \bar{\gamma}_{y}\left(v_{1}\right), \bar{\gamma}_{x}\left(v_{1}\right)
$$

that

$$
\begin{array}{r}
d_{X_{v_{1}}}\left(\gamma_{x}\left(v_{1}\right), \bar{\gamma}_{x}\left(v_{1}\right)\right) \leq 2 R_{2.49}(\overline{\bar{K}}, 1)+L_{1.99}\left(\delta_{0}, \delta_{0}\right)\left(1+D_{1.120}\left(\delta_{0}, \delta_{0}\right)\right)+M_{\bar{K}} \\
+D_{1.120}\left(\delta_{0}, \delta_{0}\right)= \\
2 R_{2.49}(\overline{\bar{K}}, 1)+M_{\bar{K}}+\delta_{0}\left(21+72 \delta_{0}\right)
\end{array}
$$

(see Remark 1.100). By combining this inequality with (3.26) and (3.25), we obtain the upper bound

$$
\begin{array}{r}
\max \left\{d_{X_{v_{1}}}\left(\gamma_{x}\left(v_{1}\right), \gamma_{y}\left(v_{1}\right)\right), d_{X_{v_{1}}}\left(\gamma_{x}\left(v_{1}\right), \bar{\gamma}_{x}\left(v_{1}\right)\right), d_{X_{v_{1}}}\left(\gamma_{y}\left(v_{1}\right), \bar{\gamma}_{y}\left(v_{1}\right)\right)\right\} \leq \\
2 R_{2.49}(\overline{\bar{K}}, 1)+M_{\bar{K}}+\delta_{0}\left(21+72 \delta_{0}\right) \leq C_{3.54} .
\end{array}
$$

This proves the inequality in the claim in the subcase (i).
Subcase (ii): Suppose $W \neq \emptyset$; hence,

$$
d_{X_{v_{1}}}\left(\bar{\gamma}_{x}\left(v_{1}\right), \bar{\gamma}_{y}\left(v_{1}\right)\right) \geq D_{1.120}\left(\delta_{0}, \delta_{0}\right)=9 \delta_{0}
$$

By Lemma 1.120,

$$
\max \left(d_{\left.{v_{v_{1}}}\left(\bar{\gamma}_{x}\left(v_{1}\right), \overline{\bar{\gamma}}_{x}\left(v_{1}\right)\right), d_{X_{v_{1}}}\left(\bar{\gamma}_{y}\left(v_{1}\right), \overline{\bar{\gamma}}_{y}\left(v_{1}\right)\right)\right) \leq R_{1.120}\left(\delta_{0}, \delta_{0}\right)=6 \delta_{0} . . . . ~ . ~}^{\text {. }}\right.
$$

Combining this inequality with Remark 3.52(6) and the triangle inequality, we obtain

$$
\begin{aligned}
d_{X_{v_{1}}}\left(\bar{\gamma}_{x}\left(v_{1}\right), \gamma_{x}\left(v_{1}\right)\right) \leq d_{X_{v_{1}}}\left(\bar{\gamma}_{x}\left(v_{1}\right), \overline{\bar{\gamma}}_{x}\left(v_{1}\right)\right)+ & d_{X_{v_{1}}}\left(\overline{\bar{\gamma}}_{x}\left(v_{1}\right), \gamma_{x}\left(v_{1}\right)\right) \\
\leq & 6 \delta_{0}+R_{2.49}(\overline{\bar{K}}, 1)
\end{aligned}
$$

and, similarly,

$$
d_{X_{v_{1}}}\left(\bar{\gamma}_{y}\left(v_{1}\right), \gamma_{y}\left(v_{1}\right)\right) \leq 6 \delta_{0}+R_{2.49}(\overline{\bar{K}}, 1) \leq C_{3.54}
$$

This establishes two out of three bounds in the claim.
Lastly, we get a bound on $d_{X_{v_{1}}}\left(\gamma_{x}\left(v_{1}\right), \gamma_{y}\left(v_{1}\right)\right)$. If $v_{1}=v$ then the bound definitely holds since $d_{X_{v}}\left(\gamma_{x}(v), \gamma_{y}(v)\right)=d_{X_{v}}(x, y) \leq 1$ by the assumption of the proposition.

Otherwise, by the definition of $v_{1}$, if $v_{2}$ is the vertex in $\llbracket v_{1}, v \rrbracket$ adjacent to $v_{1}$, then

$$
d_{X_{v_{2}}}\left(\bar{\gamma}_{x}\left(v_{2}\right), \bar{\gamma}_{y}\left(v_{2}\right)\right)<9 \delta_{0}=D_{1.120}\left(\delta_{0}, \delta_{0}\right)
$$

Hence, by Corollary 2.39, we have $d_{X_{v_{1}}}\left(\bar{\gamma}_{x}\left(v_{1}\right), \bar{\gamma}_{y}\left(v_{1}\right)\right) \leq D_{2.39}\left(\bar{K}, 9 \delta_{0}\right)$. By Remark 3.52(1)

$$
\left.d_{X_{v_{1}}}\left(\overline{\bar{\gamma}}_{x}\left(v_{1}\right)\right), \overline{\bar{\gamma}}_{y}\left(v_{1}\right)\right) \leq 9 \delta_{0}\left(1+D_{2.39}\left(\bar{K}, 9 \delta_{0}\right)\right)
$$

Hence, using Remark 3.52(6), we obtain

$$
d_{X_{v_{1}}}\left(\gamma_{x}\left(v_{1}\right), \gamma_{y}\left(v_{1}\right)\right) \leq 2 R_{2.49}(\overline{\bar{K}}, 1)+9 \delta_{0}\left(1+D_{2.39}\left(\bar{K}, 9 \delta_{0}\right)\right) \leq C_{3.54}
$$

This completes the proof of the claim.
We now prove the proposition in Case 1 . By Corollary 2.49 applied to the $\bar{K}$-qi sections $\gamma_{x}$ and $\bar{\gamma}_{x}$ over the interval $\llbracket t_{x}, v_{1} \rrbracket$, in view of the bound in Claim 3.54, since

$$
M_{\bar{K}} \leq C_{3.54},
$$

we obtain:

$$
d_{T}\left(t_{x}, v_{1}\right) \leq R_{2.49}\left(\bar{K}, C_{3.54}\right)
$$

and

$$
d_{T}\left(t_{y}, v_{1}\right) \leq R_{2.49}\left(\bar{K}, C_{3.54}\right)
$$

By the triangle inequality, $d_{X}(\rho(x), \rho(y))$ is bounded by

$$
\begin{array}{r}
d_{X_{t x}}\left(\rho(x), \gamma_{x}\left(t_{x}\right)\right)+d_{X}\left(\gamma_{x}\left(t_{x}\right), \gamma_{x}\left(v_{1}\right)\right)+d_{X_{v_{1}}}\left(\gamma_{x}\left(v_{1}\right), \gamma_{y}\left(v_{1}\right)\right)+ \\
d_{X}\left(\gamma_{y}\left(v_{1}\right), \gamma_{y}\left(t_{y}\right)\right)+d_{X_{t y}}\left(\gamma_{y}\left(t_{y}\right), \rho(y)\right) .
\end{array}
$$

Figure 9. Case 1.
This, in turn, is bounded by

$$
\begin{array}{r}
M_{\bar{K}}+K d_{T}\left(t_{x}, v_{1}\right)+K d_{T}\left(t_{y}, v_{1}\right)+d_{X_{v_{1}}}\left(\gamma_{x}\left(v_{1}\right), \gamma_{y}\left(v_{1}\right)\right)+K d_{T}\left(t_{x}, v_{1}\right)+M_{\bar{K}} \leq \\
2\left(M_{\bar{K}}+R_{2.49}\left(\bar{K}, C_{3.54}\right)\right)+C_{3.54}
\end{array}
$$

This concludes the proof of the proposition in Case 1.
Case 2: Assume that $v \notin \llbracket u, w \rrbracket$. Let $z$ denote the nearest point projection of $b$ to $\llbracket u, w \rrbracket$ in $T$. There are three subcases to be dealt with.

Subcase (i): Suppose $t_{x}, t_{y} \in \llbracket b, z \rrbracket$. Letting $v_{1}=t_{x}, v_{2}=t_{y}$ and applying Lemma 3.53(ii) with $r=r_{1}=M_{\bar{K}}$ we obtain

$$
d\left(\gamma_{x}\left(t_{x}\right), \gamma_{y}\left(t_{y}\right)\right) \leq R_{3.53}\left(K, M_{\bar{K}}, D^{\prime}\right),
$$

and, hence,

$$
d(\rho(x), \rho(y)) \leq 2 M_{\bar{K}}+R_{3.53}\left(K, M_{\bar{K}}, D^{\prime}\right)
$$

Observe that we need uniform $k$-flaring for

$$
k=k_{3.53}=K^{\prime}+R_{2.49}\left(\bar{K}, r_{1}\right), r_{1}=M_{\bar{K}}
$$

Subcase (ii): Suppose $t_{x} \in \llbracket u, z \rrbracket$ and $t_{y} \in \llbracket b, z \rrbracket$, or vice versa.
Without loss of generality, we may assume that $t_{x} \in \llbracket u, z \rrbracket$ and $t_{y} \in \llbracket b, z \rrbracket$. We first get a uniform upper bound on $d_{X_{z}}\left(\bar{\gamma}_{x}(z), \overline{\bar{\gamma}}_{x}(z)\right)$.

By Lemma 1.102, since $Y_{z}$ is $\lambda$-quasiconvex in $X_{z}, \bar{\gamma}_{x}(z)$ lies in the $\left(\lambda+2 \delta_{0}\right)$-neighborhood of $\left[\gamma_{x}(z) \bar{\gamma}_{y}(z)\right]_{X_{z}}$ in $X_{z}$.

Since

$$
d_{X_{z}}\left(\gamma_{y}(z), \bar{\gamma}_{y}(z)\right) \leq R_{2.49}\left(\bar{K}, M_{\bar{K}}\right)
$$

by Remark 3.52(3), it follows from the $\delta_{0}$-hyperbolicity of $X_{z}$ that the Hausdorff distance between the geodesics $\left[\gamma_{x}(z) \gamma_{y}(z)\right]_{X_{z}}$ and $\left[\gamma_{x}(z) \bar{\gamma}_{y}(z)\right]_{X_{z}}$ in $X_{z}$ is at most $\delta_{0}+R_{2.49}\left(\bar{K}, M_{\bar{K}}\right)$.

Combining this with the earlier observation that

$$
\bar{\gamma}_{x}(z) \in N_{\lambda+2 \delta_{0}}^{f i b}\left(\left[\gamma_{x}(z) \bar{\gamma}_{y}(z)\right]_{X_{z}}\right)
$$

we conclude that $\bar{\gamma}_{x}(z)$ belongs to the $\left(3 \delta_{0}+\lambda+R_{2.49}\left(\bar{K}, M_{\bar{K}}\right)\right)$-neighborhood of $\left[\gamma_{x}(z) \gamma_{y}(z)\right]_{X_{z}}$ in $X_{z}$. Therefore,

$$
d_{X_{z}}\left(\bar{\gamma}_{x}(z), \overline{\bar{\gamma}}_{x}(z)\right) \leq 3 \delta_{0}+\lambda+R_{2.49}\left(\bar{K}, M_{\bar{K}}\right)
$$

Figure 10. Case 3(ii)

Since, by Remark 3.52(6),

$$
d_{X_{z}}\left(\gamma_{x}(z), \overline{\bar{\gamma}}_{x}(z)\right) \leq R_{2.49}(\overline{\bar{K}}, 1)
$$

by triangle inequality we obtain

$$
d_{X_{z}}\left(\gamma_{x}(z), \bar{\gamma}_{x}(z)\right) \leq r_{2}:=R_{2.49}(\overline{\bar{K}}, 1)+3 \delta_{0}+\lambda+R_{2.49}\left(\bar{K}, M_{\bar{K}}\right)
$$

We will apply Lemma 3.53(ii) with $r=r_{2}$ and $v_{1}=z, v_{2}=t_{y}$.
Remark 3.55. Note that in order to apply Lemma 3.53(ii) we need the uniform $k$ flaring condition for

$$
k=k_{3.53}=K^{\prime}+R_{2.49}\left(\bar{K}, r_{2}\right), r_{2}=3 \delta_{0}+\lambda+R_{2.49}(\overline{\bar{K}}, 1)+R_{2.49}\left(\bar{K}, M_{\bar{K}}\right),
$$

which is ensured by the choice of the constant $r$ in (3.17), $k$ in (3.18) and the uniform $\kappa$-flaring assumption in Theorem 3.49.

In view of the $\bar{K}$-uniform flaring condition, applied to $\gamma_{x}, \bar{\gamma}_{x}$, we have $d_{T}\left(t_{x}, z\right) \leq$ $\tau_{2.43}\left(\bar{K}, r_{2}\right)$. Hence,

$$
\begin{equation*}
d\left(\gamma_{x}\left(t_{x}\right), \gamma_{x}(z)\right) \leq K \tau_{2.43}\left(\bar{K}, r_{2}\right) \tag{3.27}
\end{equation*}
$$

Since

$$
d_{X_{t y}}\left(\gamma_{y}\left(t_{y}\right), \bar{\gamma}_{y}\left(t_{y}\right)\right) \leq M_{\bar{K}} \leq r_{2}
$$

and

$$
d_{X_{z}}\left(\gamma_{x}(z), \bar{\gamma}_{x}(z)\right) \leq r_{2},
$$

we can apply Lemma 3.53(ii) with $v_{1}=z, v_{2}=t_{y}$ and obtain:

$$
d\left(\gamma_{x}(z), \gamma_{y}\left(t_{y}\right)\right) \leq R_{3.53}\left(K, r_{2}, D^{\prime}\right)
$$

Combining this estimate with the inequality (3.27) we get

$$
d\left(\gamma_{x}\left(t_{x}\right), \gamma_{y}\left(t_{y}\right)\right) \leq K \tau_{2.43}\left(\bar{K}, r_{2}\right)+R_{3.53}\left(K, r_{2}, D^{\prime}\right)
$$

This, in turn, implies that

$$
d(\rho(x), \rho(y)) \leq K \tau_{2.43}(\bar{K}, r)+R_{3.53}(K, r)+2 M_{\bar{K}}
$$

Subcase (iii): Suppose $t_{x}, t_{y} \in \llbracket u, z \rrbracket$. Without loss of generality, after swapping $x$ and $y$ if necessary, we may assume that $t_{y} \in \llbracket t_{x}, z \rrbracket$, see Figure 11. We will show that $d_{X_{z}}\left(\gamma_{x}(z), \gamma_{y}(z)\right)$ is uniformly bounded in this subcase.

Figure 11. Case 3(iii)

Suppose first that

$$
d_{X_{z}}\left(\overline{\bar{\gamma}}_{x}(z), \overline{\bar{\gamma}}_{y}(z)\right) \geq 9 \delta_{0}=D_{1.120}\left(\delta_{0}, \delta_{0}\right)
$$

Then (by Lemma 1.120) both points $\overline{\bar{\gamma}}_{x}(z), \overline{\bar{\gamma}}_{y}(z)$ belong to the $6 \delta_{0}=R_{1.120}\left(\delta_{0}, \delta_{0}\right)$-neighborhood of $\left[\bar{\gamma}_{x}(z) \bar{\gamma}_{y}(z)\right]_{X_{z}}$ in $X_{z}$.

However, by Remark 3.52(6),

$$
d_{X_{z}}\left(\overline{\bar{\gamma}}_{x}(z), \gamma_{x}(z)\right) \leq R_{2.49}(\overline{\bar{K}}, 1) \text { and } d_{X_{z}}\left(\overline{\bar{\gamma}}_{y}(z), \gamma_{y}(z)\right) \leq R_{2.49}(\overline{\bar{K}}, 1)
$$

Thus, since $Y_{z}$ is $\lambda$-quasiconvex in $X_{z}$ and both endpoints of $\left[\bar{\gamma}_{x}(z) \bar{\gamma}_{y}(z)\right]_{X_{z}}$ are in $Y_{z}$, the above inequalities imply:

$$
d_{X_{z}}\left(\gamma_{x}(z), Y_{z}\right) \leq r_{3}:=\lambda+R_{2.49}(\overline{\bar{K}}, 1)+6 \delta_{0}
$$

and

$$
d_{X_{z}}\left(\gamma_{y}(z), Y_{z}\right) \leq r_{3} .
$$

Since $\bar{\gamma}_{x}(z)$ is a nearest-point projection (in $X_{z}$ ) of $\gamma_{x}(z)$ to $Y_{z}$, it follows that

$$
d_{X_{z}}\left(\gamma_{x}(z), \bar{\gamma}_{x}(z)\right) \leq r_{3},
$$

and, similarly,

$$
d_{X_{z}}\left(\gamma_{y}(z), \bar{\gamma}_{y}(z)\right) \leq r_{3} .
$$

We are now again in position to apply Lemma 3.53(iii) with $r=r_{3}, v_{1}=v_{2}=z$ and conclude that

$$
d_{X_{z}}\left(\gamma_{x}(z), \gamma_{y}(z)\right) \leq R_{2.49}\left(k, \max \left(1, D^{\prime}\right)\right)
$$

where $k=K^{\prime}+R_{2.49}\left(\bar{K}, r_{3}\right)$.
Remark 3.56. Observe that in order to apply Lemma 3.53(iii), we need the uniform $k$-flaring condition for this $k$ and

$$
r_{3}:=\lambda+R_{2.49}(\overline{\bar{K}}, 1)+6 \delta_{0}
$$

which is ensured by the choice of the parameter $r$ in (3.17) and the uniform $\kappa$-flaring assumption in Theorem 3.49.

The uniform $\bar{K}$-flaring condition in $\mathfrak{X}$ applied to the pairs of $\bar{K}$-qi sections $\left(\gamma_{x}, \bar{\gamma}_{x}\right)$, ( $\gamma_{y}, \bar{\gamma}_{y}$ ), then implies the inequality

$$
\max \left(d_{T}\left(t_{x}, z\right), d_{T}\left(t_{y}, z\right)\right) \leq \tau_{2.43}\left(\bar{K}, r_{3}\right)
$$

Hence,

$$
\max \left(d\left(\rho(x), \gamma_{x}(z)\right), d\left(\rho(y), \gamma_{y}(z)\right)\right) \leq \bar{K} \tau_{2.43}\left(\bar{K}, r_{3}\right)+M_{\bar{K}} .
$$

By the triangle inequality we get

$$
d(\rho(x), \rho(y)) \leq 2\left(\bar{K} \tau_{2.43}\left(\bar{K}, r_{3}\right)+M_{\bar{K}}\right)+R_{2.49}\left(k, \max \left(1, D^{\prime}\right)\right)
$$

This concludes the argument in subcase (iii) and, hence, the proof of Proposition 3.51.
The following is an immediate corollary of the proposition:
Corollary 3.57. For each vertex $v \in \llbracket u, w \rrbracket$ the restriction of the retraction $\rho$ to the subspace $Z_{v}$ is $C_{3.51}\left(\lambda, K, K^{\prime}, D^{\prime}\right)$-coarse Lipschitz. This bound is independent of the choice of the paths $\gamma_{x}, \gamma_{y}$ as above.

Lemma 3.58. If $\pi(x)=v_{1}, \pi(y)=v_{2}, d_{T}\left(v_{1}, v_{2}\right)=1$ and $d_{X_{v_{1} v_{2}}}(x, y) \leq K$, then $d(\rho(x), \rho(y)) \leq C_{3.58}\left(\lambda, K, K^{\prime}, D^{\prime}\right)$.

Proof. Without loss of generality, we may assume that $d\left(u, v_{2}\right)=d\left(u, v_{1}\right)+1$. Let $y_{1}=\gamma_{y}\left(v_{1}\right)$. Since $d\left(x, y_{1}\right) \leq 2 K$, we also have

$$
d_{X_{v_{1}}}\left(x, y_{1}\right) \leq \eta_{0}(2 K)
$$

Applying Corollary 3.57 to the points $x, y_{1} \in X_{v_{1}}$, we obtain:

$$
d\left(\rho(x), \rho\left(y_{1}\right)\right) \leq C_{3.51}\left(\lambda, K, K^{\prime}, D^{\prime}\right)\left(\eta_{0}(2 K)+1\right)
$$

We next note that, without loss of generality we may assume that $\gamma_{y_{1}}$ is chosen to be the restriction of $\gamma_{y}$ to the subinterval $\llbracket u, v_{1} \rrbracket$ since the Lipschitz bound in Corollary 3.57 holds regardless of the choice of the sections $\gamma_{y}$. Hence,

$$
d(\rho(x), \rho(y)) \leq C_{3.51}\left(\lambda, K, K^{\prime}, D^{\prime}\right)\left(\eta_{0}(2 K)+1\right)
$$

This completes the proof of Theorem 3.49.
The next corollary is immediate from Theorem 3.49:
Corollary 3.59. The map $\rho$ in Theorem 3.49 is "coarsely independent" of the choice of paths $\gamma_{x}$ used in its construction. More precisely, if $\rho, \rho^{\prime}$ are two projections defined using different choices of paths $\gamma_{x}$, then

$$
d\left(\rho(x), \rho^{\prime}(x)\right) \leq L_{3.49}\left(\lambda, K, K^{\prime}, D^{\prime}\right)
$$

Recall that for $x \in \mathcal{Z}$ we defined a path $c_{x}$ in $Z$ connecting $x$ to $\rho(x)$, see Definition 3.50.

Corollary 3.60. Under the assumptions of Theorem 3.49, for any two points $x, y \in Z$ within distance $C$ from each other, the Hausdorff distance between the paths $c_{x}, c_{y}$ is $\leq$ $D_{3.60}\left(\lambda, K, K^{\prime}, D^{\prime}, C\right)$.

Proof. As in the proof of Theorem 3.49, it suffices to verify the claim in two cases:
Case 1: Suppose that $x, y \in Z_{v}$ and $d(x, y) \leq C$. Without loss of generality we may assume that $t_{y} \in \llbracket t_{x}, v \rrbracket$. By Theorem 3.49 we have

$$
d_{T}\left(\pi\left(t_{x}\right), \pi\left(t_{y}\right)\right) \leq d(\rho(x), \rho(y)) \leq L_{3.49}\left(\lambda, K, K^{\prime}, D^{\prime}\right) \cdot(C+1)
$$

Hence, the length of the portion of $c_{x}$ between $\gamma_{x}\left(t_{y}\right)$ and $\rho(x)$ is at most

$$
M_{\bar{K}}+K \cdot L_{3.49}\left(\lambda, K, K^{\prime}, D^{\prime}\right) \cdot(C+1)
$$

It follows that

$$
d_{X}\left(\gamma_{x}\left(t_{y}\right), \gamma_{y}\left(t_{y}\right)\right) \leq R_{1}:=L_{3.49}\left(\lambda, K, D^{\prime}\right)+2 M_{\bar{K}}+K \cdot L_{3.49}\left(\lambda, K, K^{\prime}, D^{\prime}\right) \cdot(C+1)
$$

Since $X_{t y}$ is $\eta_{0}$-uniformly properly embedded in $X$, we also obtain

$$
d_{X_{t y}}\left(\gamma_{x}\left(t_{y}\right), \gamma_{y}\left(t_{y}\right)\right) \leq R_{2}:=\eta_{0}\left(R_{1}\right)
$$

By Corollary 2.49, we obtain that for all vertices $s \in V\left(\llbracket t_{y}, v \rrbracket\right)$

$$
d_{X_{s}}\left(\gamma_{x}(s), \gamma_{y}(s)\right) \leq R_{3}:=R_{2.49}\left(K, \max \left(R_{2}, C\right)\right)
$$

By combining this with the earlier estimate on the length of the portion of $c_{x}$ between $\gamma_{x}\left(t_{y}\right)$ and $\rho(x)$, we obtain that the Hausdorff distance between $c_{x}, c_{y}$ is at most

$$
R_{4}:=M_{\bar{K}}+K \cdot L_{3.49}\left(\lambda, K, K^{\prime}, D^{\prime}\right) \cdot(C+1)+M_{\bar{K}}+R_{3}
$$

This concludes the proof in Case 1.
Remark 3.61. This argument also proves that if in the definition of $\rho(x)$ and $c_{x}$ we use different $K$-qi sections $\gamma_{x}^{\prime}, \gamma_{x}^{\prime \prime}$, then the resulting paths $c_{y}^{\prime}, c_{y}^{\prime \prime}$ are within Hausdorff distance $R_{4}$ from each other.

Case 2: Suppose that $\pi(x)=v_{1}, v_{2}=\pi(y), d_{T}\left(v_{1}, v_{2}\right)=1$ and $d(x, y) \leq K$. Without loss of generality we may assume that $d\left(u, v_{2}\right)=d\left(u, v_{1}\right)+1$. Setting $y_{1}:=\gamma_{y}\left(v_{1}\right)$, according to Case 1 and the above remark, we obtain the bound $R_{4}$ on the Hausdorff distance between $c_{x}$ and $c_{y_{1}}$. It follows that the Hausdorff distance between $c_{x}$ and $c_{y}$ is $\leq K+R_{4}$.

Proposition 3.62. Under the assumptions of Theorem 3.49, assuming, in addition, that $Z$ is $\delta$-hyperbolic, there exists $C=C_{3.62}\left(\delta, \lambda, K, K^{\prime}, D^{\prime}\right)$ such that $d\left(\rho_{Y}, P\right) \leq C$, where $P=P_{Z, Y}$ is the nearest-point projection in $Z$.

Proof. By Theorem 3.49, there exists a coarse $L=L_{3.49}\left(\lambda, K, K^{\prime}, D^{\prime}\right)$-Lipschitz retraction $\rho: Z \rightarrow Y$. By Lemma 1.101, the subset $Y$ is $\lambda^{\prime}=\lambda_{1.101}(L, \delta)$-quasiconvex in Z.

By the construction of $\rho$, the path $c_{x}$ connecting $x \in Q_{\nu}$ to $\bar{x}=\rho_{Y}(x)$ is the concatenation of the $K$-qi section $\gamma_{x, \tilde{x}}$ and the vertical geodesic $[\tilde{x} \bar{x}]_{X_{t}}$ of length $\leq M_{\bar{K}}, t=t_{x}$. Hence, considering the geodesic triangle $\Delta x \tilde{x} \bar{x}$ in $Z$ and using the $\delta$-hyperbolicity of $Z$, we conclude that

$$
\operatorname{Hd}_{Z}\left(\gamma_{x, \tilde{x}},[x \bar{x}]_{Z}\right) \leq \delta+M_{\bar{K}}+D_{1.53}(\delta, K) .
$$

Therefore, since $Y$ is $\lambda^{\prime}$-quasiconvex in $Z$, in order to prove the proposition, according to Corollary 1.106, it suffices to verify that there exists a function $R \mapsto R^{\prime}$ (depending on $\delta, \lambda^{\prime}$ ) such that for all $v \in V(\pi(Z)), x \in Q_{v}, y \in \mathcal{Y}$

$$
d_{Z}\left(y, \gamma_{x, \tilde{x}} \cap \mathcal{X}\right) \leq R \Rightarrow d_{Y}(y, \bar{x}) \leq R^{\prime}
$$

Our goal then is to define such a function.
Take $y \in \mathcal{Y}$ such that $d_{Z}\left(y, \gamma_{x, \tilde{x}}\right) \leq R$. Pick a point

$$
x^{\prime} \in \gamma_{x, \tilde{x}} \cap X_{v^{\prime}}, v^{\prime} \in \llbracket u, v \rrbracket,
$$

such that $d_{Z}\left(y, x^{\prime}\right) \leq R$. In particular, $d_{T}\left(v^{\prime}, \pi(y)\right) \leq R$.

Let $b$ denote the center of the tripod $\Delta v^{\prime} \pi(y) u \subset T$,

$$
b \in \llbracket u, v^{\prime} \rrbracket \subset \llbracket u, v \rrbracket,
$$

see Figure 3.4. Then

$$
\begin{equation*}
d_{T}\left(v^{\prime}, b\right)+d_{T}(b, \pi(y))=d_{T}\left(v^{\prime}, \pi(y)\right) \leq R . \tag{3.28}
\end{equation*}
$$

Set $x^{\prime \prime}:=\gamma_{x}(b)$ (this point is defined since $b \in \llbracket u, v \rrbracket$ and $\gamma_{x}$ is a section over that interval) and let $\gamma^{\prime \prime}$ denote $\gamma_{x^{\prime \prime}, \tilde{x}}$, the restriction of $\gamma_{x}$ to $\llbracket b, t \rrbracket$. (Note that the order in which the vertices $t, b$ appear in the interval $\llbracket u, v^{\prime} \rrbracket$ is unclear.)

Let $\bar{\gamma}^{\prime \prime}$ denote the fiberwise projection of $\gamma^{\prime \prime}$ to $\mathcal{Y}_{t b}$; without loss of generality, $\bar{\gamma}^{\prime \prime}(b)=$ $\bar{x}$. Then $\bar{\gamma}$ is a $\bar{K}$-qi leaf in $Y$ connecting $\bar{x}$ to $\bar{x}^{\prime \prime}=P_{X_{b}, Y_{b}}\left(x^{\prime \prime}\right)$.

Furthermore, let $\gamma_{y}$ be a $K^{\prime}$-qi section in $Y$ over $\llbracket \pi(y), u \rrbracket$, connecting $y$ to $Y_{u}$ and let $\gamma_{y}^{\prime \prime}$ be its restriction to the interval $\llbracket \pi(y), b \rrbracket$ (recall that $b \in \llbracket \pi(y), u \rrbracket)$. Set $y^{\prime \prime}:=\gamma_{y}(b)=\gamma_{y}^{\prime \prime}(b)$.

Now, consider the quadruple of points $x^{\prime \prime}, x^{\prime}, y, y^{\prime \prime}$ : We have a $K$-qi section $\gamma_{x^{\prime \prime}, x^{\prime}}$ connecting $x^{\prime \prime}$ to $x^{\prime}$, a geodesic $\left[x^{\prime} y\right]_{Z}$ in $Z$ connecting $x^{\prime}$ to $y$ and the $K^{\prime}$-qi section $\gamma_{y}^{\prime \prime}$ connecting $y$ to $y^{\prime \prime}$. Therefore,

$$
d_{Z}\left(y, y^{\prime \prime}\right) \leq K^{\prime} d_{T}(\pi(y), b)
$$

and

$$
d_{Z}\left(x^{\prime \prime}, y^{\prime \prime}\right) \leq K d_{T}\left(b, v^{\prime}\right)+R+K^{\prime} d_{T}(\pi(y), b) .
$$

Taking into account the inequality (3.28), we obtain

$$
\begin{gather*}
d_{Z}\left(x^{\prime \prime}, y^{\prime \prime}\right) \leq R+\max \left(K, K^{\prime}\right) d_{T}\left(\pi(y), v^{\prime}\right) \leq  \tag{3.29}\\
R+R \max \left(K, K^{\prime}\right)=R\left(1+\max \left(K, K^{\prime}\right)\right) \\
d_{Z}\left(y, y^{\prime \prime}\right) \leq K^{\prime} d_{T}\left(\pi(y), v^{\prime}\right) \leq K^{\prime} R \tag{3.30}
\end{gather*}
$$

Since $x^{\prime \prime}, y^{\prime \prime} \in X_{b}$, we also get

$$
\begin{equation*}
\left.d_{X_{b}}\left(x^{\prime \prime}, y^{\prime \prime}\right) \leq \eta_{0} R\left(1+\max \left(K, K^{\prime}\right)\right)\right) \tag{3.31}
\end{equation*}
$$

Since $y^{\prime \prime} \in Y_{b}$ and $\bar{x}^{\prime \prime}$ is the projection of $x^{\prime \prime}$ to $Y_{b}$, it follows that

$$
\begin{equation*}
d_{X_{b}}\left(x^{\prime \prime}, \bar{x}^{\prime \prime}\right) \leq \eta_{0}\left(R\left(1+\max \left(K, K^{\prime}\right)\right)\right) . \tag{3.32}
\end{equation*}
$$

The uniform $\bar{K}$-flaring condition applied to the restrictions of $\gamma^{\prime \prime}$ and $\bar{\gamma}$ to $\llbracket t, b \rrbracket$, and the inequalities

$$
\begin{array}{r}
d_{X_{b}}\left(\gamma^{\prime \prime}(b), \bar{\gamma}^{\prime \prime}(b)\right) \leq \eta_{0}\left(R\left(1+\max \left(K, K^{\prime}\right)\right)\right), \\
d_{X_{t}}\left(\gamma^{\prime \prime}(t), \bar{\gamma}^{\prime \prime}(t)\right)=d_{X_{t}}(\tilde{x}, \bar{x}) \leq M_{K^{\prime}}, \tag{3.33}
\end{array}
$$

imply that

$$
d_{T}(t, b) \leq \tau_{2.43}\left(\bar{K}, \max \left(\eta_{0} R\left(1+\max \left(K, K^{\prime}\right)\right)\right), M_{K^{\prime}}\right) .
$$

In particular,

$$
\begin{equation*}
d\left(\bar{x}, \bar{x}^{\prime \prime}\right) \leq \bar{K} \tau_{2.43}\left(\bar{K}, \max \left(\eta_{0} R\left(1+\max \left(K, K^{\prime}\right)\right)\right), M_{K^{\prime}}\right) . \tag{3.34}
\end{equation*}
$$

Putting together the inequalities (3.34), (3.32), (3.31), (3.30), by the triangle inequality, we get:

$$
\begin{array}{r}
d_{Z}(\bar{x}, y) \leq d_{Z}\left(\bar{x}, \bar{x}^{\prime \prime}\right)+d_{Z}\left(\bar{x}^{\prime \prime}, x^{\prime \prime}\right)+d_{Z}\left(x^{\prime \prime}, y^{\prime \prime}\right)+d_{Z}\left(y^{\prime \prime}, y\right) \leq \\
R^{\prime}:= \\
\bar{K} \tau_{2.43}\left(\bar{K}, \max \left(\eta_{0} R\left(1+\max \left(K, K^{\prime}\right)\right)\right), M_{K^{\prime}}\right)+ \\
\eta_{0} R\left(1+\max \left(K, K^{\prime}\right)\right)+ \\
R\left(1+\max \left(K, K^{\prime}\right)\right)+K^{\prime} R .
\end{array}
$$

This proves the proposition.
Combining Theorem 3.49 with the existence of uniformly coarse Lipschitz retractions $X \rightarrow Z$, where $Z=F l_{K}\left(Q_{u}\right)$ or $Z=L_{K}(\alpha)$, (Theorem 3.21, Corollary 3.13), we obtain:

Corollary 3.63. Suppose that $Y \subset N_{4 \delta_{0}}^{f i b}\left(F l_{K}\left(Q_{u}\right)\right) \subset X$ or $A_{K^{\prime}, D^{\prime}}\left(\alpha^{\prime}\right) \subset L=L_{K, D, E}(\alpha)$ satisfy the assumptions of Theorem 3.49 with parameters $\lambda, K, D, E, K^{\prime}$ and $D^{\prime}$. Then there exists a coarse $L_{3.63}\left(\lambda, K, K^{\prime}, D, D^{\prime}, E\right)$-Lipschitz retraction $\rho_{Y}: X \rightarrow Y$.

Remark 3.64. 1. It follows that if $X$ were hyperbolic, then the total space $A$ of each ( $K^{\prime}, D^{\prime}$ )-carpet $\mathfrak{A}_{K^{\prime}, D^{\prime}}\left(\alpha^{\prime}\right)$ would be uniformly quasiconvex in $X$.
2. Unlike the existence theorem for coarse Lipschitz retractions to semicontinuous subtrees of spaces, in order to get a uniform coarse Lipschitz retractions to carpets (and to bundles) we do not need lower bounds on $K$ besides the obvious inequality $K \geq 1$.

## CHAPTER 4

## Hyperbolicity of ladders

In this chapter we prove uniform hyperbolicity of $(K, D, E)$-ladders in $X$. The proof is divided in three main steps. We first prove (section 4.1) hyperbolicity of carpets by exhibiting slim combings of carpets (combings satisfying the conditions of Corollary 1.64). We use these paths, in conjunction with the retractions to carpets (see Corollary 3.63) to construct combings of carpeted ladders, which are ladders $\mathfrak{L}(\alpha)$ containing carpets $\mathfrak{H}\left(\alpha^{\prime}\right)$ with $\alpha^{\prime} \subset \alpha$ whose length almost equals that of $\alpha$. This is done in Section 4.2. Lastly, in Section 4.3 we prove hyperbolicity of general ladders subdividing these (a "vertical subdivision") into carpeted ladders and then using quasiconvex amalgamation to prove hyperbolicity. Hyperbolicity of ladders is a key step for proving hyperbolicity of flowspaces, which is done in the next chapter.

### 4.1. Hyperbolicity of carpets

The proof of the following simple proposition will serve as a model for more complex proofs of hyperbolicity of certain subspaces of $X$.

Proposition 4.1. For every $K \geq 1$, every $(K, C)$-narrow carpet $\mathfrak{A}=(\pi: A \rightarrow \llbracket u, w \rrbracket)$ in $\mathfrak{X}$, equipped with its intrinsic metric, is $\delta_{4.1}(K, C)$-hyperbolic, provided that $\mathfrak{X}$ satisfies the uniform $K$-flaring condition.

Proof. Let $\beta=\mathcal{A} \cap X_{w}$ denote the $C$-narrow end of $\mathfrak{A}$. For each $x \in \mathcal{A}$ we have the $K$-qi section $\gamma_{x} \subset \Sigma_{x}$ of $\pi: A \rightarrow \llbracket u, w \rrbracket$ over $\llbracket \pi(x), w \rrbracket$, connecting $x$ to $\beta$. For any two such sections $\gamma_{x}, \gamma_{y}$ we let $t_{x y} \in V(\llbracket w, u \rrbracket)$ denote the supremum of

$$
\left\{t \in V(\llbracket w, u \rrbracket): d_{X_{t}}\left(\gamma_{x}(t), \gamma_{y}(t)\right) \leq M_{K}\right\} .
$$

In particular, if this subset is empty, then $t_{x, y}=w$. Set $t:=t_{x y}$. We then define a path $c(x, y)$ as the concatenation of the section $\gamma_{x}$ restricted to $\llbracket \pi(x), t \rrbracket$ with the vertical segment $\left[\gamma_{x}(t) \gamma_{y}(t)\right]_{X_{t}}$, followed by the concatenation with the restriction of the section $\gamma_{y}$ to the subinterval $\llbracket t, \pi(y) \rrbracket$. The assumption that $\mathcal{A}$ is $(K, C)$-narrow implies that the length of $\left[\gamma_{x}(t) \gamma_{y}(t)\right]_{X_{t}}$ is at most

$$
\max \left(C, M_{K}\right)
$$

We claim that this family of paths in $A$ satisfies the conditions of Corollary 1.64 with constants depending only on $K$ and $C$. The assumption that the paths $c(x, y)$ are uniformly coarse Lipschitz follows from the fact that each path $c(x, y)$ is a concatenation of $K$-qi sections and of vertical geodesics.

Lemma 4.2. The family of paths $c(x, y)$ is uniformly proper in $A$, with distortion function depending only on $K$ and $C$.

Proof. Let $x, y \in \mathcal{A}$ be such that $d(x, y) \leq r$. Set $v_{1}:=\pi(x), v_{2}:=\pi(y)$. Then $d_{T}\left(v_{1}, v_{2}\right) \leq r$ as well. Without loss of generality, on the oriented interval $\llbracket w, u \rrbracket$ we have

$$
w \leq t_{x y} \leq v_{1} \leq v_{2} \leq u
$$

Let $y_{1} \in A_{v_{1}}$ be the intersection point with $\gamma_{y}$. Then the subpath $\gamma_{y y_{1}}$ in $\gamma_{y}$ between $y, y_{1}$ has length $\leq K r$ and $d\left(y_{1}, x\right) \leq r_{1}=r(K+1)$. Furthermore, $d_{X_{v_{1}}}\left(y_{1}, x\right) \leq \eta_{0}\left(r_{1}\right)$. By the uniform $K$-flaring condition,

$$
d_{T}\left(v_{1}, t_{x y}\right) \leq \tau_{2.43}\left(K, \max \left(M_{K}, C, \eta_{0}\left(r_{1}\right)\right)\right) .
$$

Therefore, the overall length of $c(x, y)$ is

$$
\leq \max \left(M_{K}, C\right)+2 K \tau_{2.43}\left(K, \max \left(M_{K}, C, \eta_{0}\left(r_{1}\right)\right)\right)+K r
$$

Remark 4.3. This lemma is the only place where the constant $C$ plays any role in the proof of the proposition.

We next verify the condition (a2) of Corollary 1.64 for the family of paths $c(x, y)$. First of all, in the special case of (a2) when $d(y, z)$ is uniformly bounded, the paths $c(x, y), c(x, z)$ are uniformly close (fellow-travel), as follows from Corollary 2.49. (The bounds depend only on $K$ and on $d(y, z)$.)

Consider now three points $x, y, z \in \mathcal{A}$ and the triangle $\Delta$ formed by the paths $c(x, y)$, $c(y, z), c(z, x)$ connecting them. After relabelling the points $x, y, z$ we can assume that the vertices $t_{x y}, t_{y z}, t_{z x}$ appear in the interval $\llbracket u, w \rrbracket$ in the following order:

$$
u \leq t_{x y} \leq t_{y z} \leq t_{z x} \leq w
$$

Case 1. Suppose first that $t:=t_{x y}<w$. Then

$$
d_{X_{t}}\left(\gamma_{x}(t), \gamma_{y}(t)\right) \leq M_{K}
$$

Therefore, we replace $x, y$ with $x^{\prime}:=\gamma_{x}(t), y^{\prime}:=\gamma_{y}(t)$ respectively; $d_{X_{t}}\left(x^{\prime}, y^{\prime}\right) \leq M_{K}$, i.e. the length of the path $c\left(x^{\prime}, y^{\prime}\right)$ is $\leq M_{K}$. Thus, $\delta_{4.1}(K)$-slimness of the triangle $\Delta^{\prime}=\Delta x^{\prime} y^{\prime} z$ formed by the paths $c\left(x^{\prime}, y^{\prime}\right), c\left(y^{\prime}, z\right), c\left(z, x^{\prime}\right)$ follows from the uniform fellow-traveling property of the paths $c$ in $\mathfrak{A}$. Since, without loss of generality we may assume that $c\left(y^{\prime}, z\right), c\left(z, x^{\prime}\right)$ are subpaths in $c(y, z), c(z, x)$, we conclude the $\delta_{4.1}(K)$-slimness of the original triangle $\Delta$.

Case 2. It remains to consider the case $t_{x y}=t_{y z}=t_{z x}=w$. Then, as in Case 1, we replace the points $x, y, z$ with the points $x^{\prime}:=\gamma_{x}(w), y^{\prime}:=\gamma_{y}(w), z^{\prime}=\gamma_{z}(w)$. The triangle $\Delta^{\prime}$ formed by the paths $c\left(x^{\prime}, y^{\prime}\right), c\left(y^{\prime}, z^{\prime}\right), c\left(z^{\prime}, x^{\prime}\right)$ is contained in the geodesic segment $\beta$; hence $\Delta^{\prime}$ is $\delta_{0}$-slim. We conclude that $\Delta$ is $\delta_{4.1}(K)$-slim as well.

Remark 4.4. Lemma 4.2 establishes that the paths $c(x, y)$ are uniformly proper (with distortion depending only on $K$ and $C$ ). Hence, by Corollary 1.64(b), the paths $c(x, y)$ are uniformly (in terms of $K$ and $C$ ) close to geodesics in $A$.

### 4.2. Hyperbolicity of carpeted ladders

Definition 4.5. Let $\bar{K}$ be defined as in Notation 3.48, with $K^{\prime}=K, \lambda=\delta_{0}$,

$$
\begin{equation*}
\bar{K}:=K_{3.47}\left(\delta_{0}, K, K\right) \tag{4.1}
\end{equation*}
$$

Set

$$
\begin{equation*}
\kappa:=\kappa_{4.5}(K)=\kappa_{3.19}\left(\delta_{0}, K, K\right) \tag{4.2}
\end{equation*}
$$

A $(K, D, E)$-ladder $\mathfrak{L}(\alpha)$ containing a $(K, C)$-carpet $\mathfrak{A}=\mathfrak{A}_{K, C}\left(\alpha^{\prime}\right), \alpha^{\prime} \subset \alpha$, as a subladder ${ }^{1}$, satisfying

$$
\text { length }\left(\alpha^{\prime}\right) \geq \operatorname{length}(\alpha)-M_{\bar{K}}
$$

will be called carpeted.

[^11]In this section, we will prove that carpeted ladders are uniformly hyperbolic. Only the parameters $K$ and $C$ will play a role in the proof, the parameters $D$ and $E$ will be irrelevant, just as in the proof of the existence of a coarse Lipschitz retraction $L_{K}(\alpha) \rightarrow A_{K, C}\left(\alpha^{\prime}\right)$.

Theorem 4.6 (Hyperbolicity of carpeted ladders). Carpeted ladders in $\mathfrak{X}$ are hyperbolic. More precisely: Fix $K \geq 1$ and suppose that that $\mathfrak{\mathfrak { t } \text { satisfies the uniform } \kappa \text { -flaring }}$ condition, where $\kappa=\kappa(K)$ is as in Definition 4.5, (4.2). Let $\mathfrak{Z}=\mathfrak{L}_{K}(\alpha)$ be a $K$-ladder containing $a(K, C)$-carpet $\mathfrak{A}\left(\alpha^{\prime}\right)$ as in Definition 4.5. Then $L_{K}(\alpha)$ (with its intrinsic metric) is $\delta_{4.6}(K, C)$-hyperbolic.

Proof. The proof of this theorem is divided in two steps: We first define a family of paths $c(x, y)$ in $L_{K}(\alpha)$ connecting points $x, y \in \mathcal{L}$, using the family of uniform quasigeodesics for the carpet $\mathfrak{A}$ as a blackbox, and then check that these paths satisfy the conditions of Corollary 1.64. We let $\llbracket u, w \rrbracket \subset S \subset T$ denote the base-interval of the carpet $\mathfrak{A}$, where $S=\pi\left(L_{K}(\alpha)\right)$ is the base of $\mathfrak{L}=\left(\pi: L_{K}(\alpha) \rightarrow S\right)$. Then $u$ is the center of both $\mathfrak{A}$ and $\mathfrak{L}, \alpha^{\prime}=A_{u}$ and $\beta=A_{w}$ is the narrow end of $\mathfrak{A}$.

For each $x \in \mathcal{L}$ we let $b_{x} \in V(T)$ denote the center of the triangle $\Delta u w \pi(x) \subset T$.
According to Theorem 3.49, there exists $\rho=\rho_{\mathfrak{Q}, \mathfrak{2}}: \mathcal{L} \rightarrow \mathcal{A}$, a coarsely $k$-Lipschitz retraction with

$$
k=L_{3.49}\left(\delta_{0}, K, K, C\right)
$$

We first review some facts about $\rho(x)$. The point $\rho(x)=\bar{x}$ belongs to the interval $A_{s} \subset \mathcal{A}$, for a certain vertex

$$
s \in \llbracket u, \pi(x) \rrbracket \cap \llbracket u, w \rrbracket,
$$

such that $\bar{x}$ is within vertical distance $M_{\bar{K}}$ (in the vertex space $X_{s}$ ) from a point $\tilde{x}=\gamma_{x}(s) \in$ $X_{s}$. Here $\gamma_{x} \subset \Sigma_{x}$ is the $K$-section in $\mathcal{L}$ over $\llbracket u, \pi(x) \rrbracket$ connecting $x$ to $\alpha$. (Such point $\bar{x}$ always exists in view of the assumption on the length of $\alpha^{\prime}$.)

The paths $\gamma_{x}^{\prime}=\gamma_{x \tilde{x}} \star[\tilde{x} \bar{x}]_{X_{s}}$ defined in the proof of Theorem 3.49, connecting $x$ to $\bar{x}$, satisfy the Hausdorff fellow-traveling property with respect to variations of $x$ (see Corollary 3.60). Here $\gamma_{x \tilde{x}}$ is a subpath of $\gamma_{x}$ connecting $x$ to $\tilde{x}$.

Figure 12. Up to relabeling $x, y$ there are two possible configurations of the points $u, w, \pi(x), \pi(y)$.

Step 1: Definition of the paths $c_{x, y}=c(x, y)$.
For $x, y \in \mathcal{L}$ we let $b=b_{x y}$ be the center of the triangle $\Delta u \pi(x) \pi(y) \subset T$. There are two cases to consider, depending on which we get two types of paths $c(x, y)$.

Paths of type 1: There exists $t \in V(\llbracket \pi(x), \pi(\bar{x}) \rrbracket \cap \llbracket \pi(y), \pi(\bar{y}) \rrbracket) \subset V(\llbracket u, b \rrbracket)$ such that

$$
d_{X_{t}}\left(\gamma_{x}(t), \gamma_{y}(t)\right) \leq M_{\bar{K}},
$$

i.e. the paths $\gamma_{x}, \gamma_{y}$ "come sufficiently close" in some common vertex-space.

Figure 13. Paths of type 1: $t=t_{x, y}$.

Let $t_{x y}$ be the maximal vertex in $\llbracket u, b \rrbracket$ with this property. Then define $c(x, y)$ to be the concatenation of the portions of $\gamma_{x}$ and (the reverse of) $\gamma_{y}$ over $\llbracket t_{x y}, \pi(x) \rrbracket$ and $\llbracket t_{x, y}, \pi(y) \rrbracket$ respectively with the subsegment of $L_{t_{x y}}$ joining their end points.

Paths of type 2: Suppose $t$ as in type 1 does not exist, i.e. the paths $\gamma_{x}, \gamma_{y}$ "stay far apart" in every vertex-space they both enter.

Then define $c(x, y)$ to be the concatenation of $\gamma_{x}^{\prime}$ and the reverse of $\gamma_{y}^{\prime}$ with a geodesic $[\bar{x} \bar{y}]_{A}$ in $A=A_{(K, C)}\left(\alpha^{\prime}\right)$ connecting $\bar{x}$ to $\bar{y}$.

Remark 4.7. More precisely, instead of geodesics $[\bar{x} \bar{y}]_{A}$ one should use uniform quasigeodesic paths in $A$ defined in the previous section. Since the two families are uniformly close to each other, we will work with geodesics for the ease of the notation. We will do the same repeatedly later in the book.

We observe that each path of type 1 is a concatenation of (at most) three uniformly quasigeodesics paths (the middle one of which has) uniformly bounded length $\leq M_{\bar{K}}$, while each path of type 2 is a concatenation of (at most) five uniformly quasigeodesics paths (two of which have uniformly bounded lengths $\leq M_{\bar{K}}$ ).

Our next task is to establish a uniform Hausdorff fellow-traveling property of the family of paths $c(x, y)$ (Lemma 4.8). Even though is property is not required by Corollary 1.64, it will play key role in verifying the other conditions of the corollary.

Lemma 4.8. The paths $c(x, y)$ satisfy the Hausdorff fellow-traveling property, i.e. if $y, z$ are uniformly close to each other (in the total space $L$ of the ladder $\mathfrak{Z}$ ), so are the images of the paths $c(x, y), c(x, z)$. More precisely, there is a function $D_{4.8}(C, K, r)$ such that if $d_{L}(y, z) \leq r$, then

$$
\operatorname{Hd}\left(c_{x, y}, c_{x, z}\right) \leq D_{4.8}(C, K, r),
$$

Proof. As in the proof of Theorem 3.49, there are two cases to consider: $\pi(y)=\pi(z)$ (see part of the proof covered in Proposition 3.51) and $d(\pi(y), \pi(z)$ ) (see part of the proof covered in Lemma 3.58). The second case follows from the first one just as in the proof of

Figure 14. Case 1-1.

Lemma 3.58, so we assume that $\pi(y)=\pi(z)$. There are three cases to check depending on the types of the paths $c(x, y), c(x, z)$.

Case 1-1: Both paths $c(x, y), c(x, z)$ have type 1. The paths $c(x, y), c(x, z)$ agree over the interval $\llbracket t, x \rrbracket$ where $t \in\left\{t_{x y}, t_{x z}\right\}$ is the vertex closer to $b_{x y}$; after swapping the roles of $y$ and $z$ we may assume that $t=t_{x z}$, see Figure 14.

Define the points

$$
x_{1}:=\gamma_{x}\left(t_{x y}\right), y_{1}:=\gamma_{y}\left(t_{x y}\right), x_{2}:=\gamma_{x}\left(t_{x z}\right), y_{2}=\gamma_{y}\left(t_{x z}\right), z_{2}:=\gamma_{z}\left(t_{x z}\right) .
$$

They satisfy the inequalities

$$
d_{X_{t x y}}\left(x_{1}, y_{1}\right) \leq M_{\bar{K}}, \quad d_{X_{t_{x z}}}\left(x_{2}, z_{2}\right) \leq M_{\bar{K}}
$$

Except for the point $y_{2}$, these are the points where the paths $c(x, y), c(x, z)$ switch from vertical to horizontal. The points $x_{1}, y_{1}, y_{2}$ lie in the image of $c(x, y)$, while the points $x_{2}, z_{2}$ lie in the image of $c(x, z)$.

We will show that the length of the interval $\llbracket t_{x y}, t_{x z} \rrbracket$ is uniformly bounded (in terms of $r$ and the other parameters in the theorem). Since

$$
d_{X_{t x y}}\left(x_{1}, y_{1}\right) \leq M_{\bar{K}},
$$

it will follow, according to Lemma 2.37 that the part of $c(x, y)$ lying between $x_{2}$ and $y_{2}$ is uniformly Hausdorff-close to the vertical segment $\left[x_{2} y_{2}\right]_{x_{x z}}$. In particular, the length of that segment will be uniformly bounded. However, the points $x_{2}$ and $z_{2}$ are within vertical distance $M_{\bar{K}}$ from each other. Hence, the vertical distance between $z_{2}$ and $y_{2}$ is also uniformly bounded. Since $d_{L}(y, z) \leq r$, by Corollary 2.49, it will follow that the vertical distance between $\gamma_{y}, \gamma_{z}$ over the interval $\llbracket t_{x z}, \pi(y) \rrbracket$ is also uniformly bounded, thereby, concluding the proof. Thus, it remains to bound the length of the interval $\llbracket t_{x y}, t_{x z} \rrbracket$.

By the definition of the projection $\rho: \mathcal{L} \rightarrow \mathcal{A}$,

$$
\rho\left(x_{1}\right)=\rho\left(x_{2}\right)=\bar{x}, \rho\left(y_{1}\right)=\bar{y}, \rho\left(z_{2}\right)=\bar{z} .
$$

Since $\rho$ is $k$-coarse Lipschitz, we have

$$
d_{A}(\bar{x}, \bar{y}) \leq k\left(M_{\bar{K}}+1\right), \quad d_{A}(\bar{x}, \bar{z}) \leq k\left(M_{\bar{K}}+1\right), \quad d_{A}(\bar{y}, \bar{z}) \leq k(r+1) .
$$

Lemma 2.47 now implies that

$$
d_{T}\left(t_{x y}, t_{x z}\right) \leq \tau_{2.47}\left(K, \max \left(k\left(M_{\bar{K}}+1\right), k(r+1)\right)\right) .
$$

This concludes the proof in Case 1-1.
Case 1-2: The path $c(x, y)$ is of type 1 while $c(x, z)$ is of type 2 . Since $c(x, y)$ has type 1 , we define the vertex

$$
t=t_{x y} \in \llbracket u, \pi(x) \rrbracket \cap \llbracket u, v \rrbracket, v=\pi(y)=\pi(z) .
$$

At this vertex

$$
\begin{equation*}
d_{X_{t}}\left(\gamma_{x}(t), \gamma_{y}(t)\right) \leq M_{\bar{K}} . \tag{4.3}
\end{equation*}
$$

All three paths $\gamma_{x}, \gamma_{y}, \gamma_{z}$ enter the same vertex space $X_{t}, t=t_{x y}$ at points $x_{1}, y_{1}, z_{1}$ respectively.

Since $\rho$ is $k$-coarse Lipschitz, and $\bar{x}=\rho(x)=\rho\left(x_{1}\right), \bar{y}=\rho(y)=\rho\left(y_{1}\right)$, we have

$$
d_{A}(\bar{x}, \bar{y}) \leq k\left(M_{\bar{K}}+1\right)
$$

Similarly, since $d_{L}(y, z) \leq r$, we obtain

$$
d_{A}(\bar{y}, \bar{z}) \leq k(r+1)
$$

Define $v_{y}:=\pi(\rho(y)), v_{z}:=\pi(\rho(z))$. Thus,

$$
\begin{aligned}
d_{T}\left(v_{y}, v_{z}\right) & \leq k(r+1) \\
d\left(\gamma_{y}\left(v_{y}\right), \gamma_{z}\left(v_{z}\right)\right) & \leq k(r+1)+M_{\bar{K}}
\end{aligned}
$$

Let $\bar{v} \in\left\{v_{y}, v_{z}\right\}$ denote the vertex further away from $u$. Thus,

$$
d\left(\gamma_{y}(\bar{v}), \gamma_{z}(\bar{v})\right) \leq k(r+1)+2 M_{\bar{K}}+2 k K(r+1) .
$$

By Corollary 2.49, the fiberwise distance between $\gamma_{y}, \gamma_{z}$ over the interval $\llbracket \bar{v}, v \rrbracket$ is at most

$$
\tau_{2.49}\left(K, \max \left(r, k(r+1)+2 M_{\bar{K}}+2 k K(r+1)\right)\right)=\tau_{2.49}\left(K, k(r+1)+2 M_{\bar{K}}+2 k K(r+1)\right) .
$$

In particular, this inequality holds at the vertex $t$ since it belongs to the interval $\llbracket \bar{v}, v \rrbracket$ :

$$
d_{X_{t}}\left(\gamma_{y}(t), \gamma_{z}(t)\right) \leq \tau_{2.49}\left(K, k(r+1)+2 M_{\bar{K}}+2 k K(r+1)\right)
$$

Hence, by (4.3),

$$
d_{X_{t}}\left(\gamma_{x}(t), \gamma_{z}(t)\right) \leq M_{\bar{K}}+\tau_{2.49}\left(K, k(r+1)+2 M_{\bar{K}}+2 k K(r+1)\right) .
$$

Define a vertex $v^{\prime}$ by

$$
\llbracket \pi(\bar{x}), t \rrbracket \cap \llbracket \pi(\bar{z}), t \rrbracket=\llbracket v^{\prime}, t \rrbracket .
$$

Since the path $c(x, z)$ has type 2 , for all $s \in V\left(\llbracket \nu^{\prime}, t \llbracket\right)$ we have the inequality

$$
d_{X_{s}}\left(\gamma_{x}(s), \gamma_{z}(s)\right)>M_{\bar{K}}
$$

Therefore, as in Case 1-1, Lemma 2.47 implies a uniform upper bound in the lengths of the intervals $\llbracket \pi(\bar{x}), t \rrbracket, \llbracket \pi(\bar{z}), t \rrbracket$. Thus, just as in Case $1-1$, we obtain a uniform upper bound on the distances $d\left(\bar{x}, x_{1}\right), d\left(\bar{z}, z_{1}\right)$ and, hence, the paths $c(x, y), c(x, z)$ uniformly Hausdorff fellow-travel.

Case 2-2: Both paths $c(x, y), c(x, z)$ have type 2 . The points $\bar{y}, \bar{z} \in \mathcal{A}$ are within distance $\leq k(r+1)$ from each other and, hence, by Corollary 2.49, the paths $\gamma_{y}^{\prime}, \gamma_{z}^{\prime}$ uniformly fellow-travel. The same holds for geodesics $[\bar{y} \bar{x}]_{A},[\bar{z} \bar{x}]_{A}$ since $A$ is $\delta_{A}=\delta_{4.1}(K, C)-$ hyperbolic. Hence, the paths $c(x, y), c(x, z)$ uniformly fellow-travel as well.

Combining this Lemma with Lemma 1.61 and the fact that each path $c(x, y)$ is a concatenation of at most five uniformly quasigeodesic paths, we obtain:

Corollary 4.9. The paths $c(x, y)$ are uniformly proper. More precisely, there is a function $\zeta_{4.9}(r, K, C)$ such that for each path $c(x, y)$ defined above, for any two points $x^{\prime}, y^{\prime}$ on $c(x, y)$, if $d\left(x^{\prime}, y^{\prime}\right) \leq r$ then the length of the portion of $c(x, y)$ between $x^{\prime}, y^{\prime}$ is $\leq \zeta_{4.9}(r, K, C)$.

Step 2: We shall now check that the paths $c$ defined on Step 1 satisfy the conditions of Corollary 1.64 to conclude the proof of the theorem.

Condition (a1): This is an immediate consequence of Lemma 4.9.
Condition (a2): The verification of the condition of uniform slimness of the triangle $\Delta$ in $X$ formed by the paths $c(x, y), c(y, z), c(z, x)$ is broken into several cases depending on the relative positions of the three points $x, y, z$ and the types of the paths $c(x, y), c(y, z), c(z, x)$ (type 1 or type 2). The trick is to reduce the proof to a simpler case by replacing $x, y, z$ with some other suitable points, analogously to the proof of Proposition 4.1 and then appeal to Proposition 4.6. For instance, suppose that there is a constant $r=r(K, C)$ such that a triangle $\Delta$ as above is $r$-thin, i.e. there exists a point $x \in X$ within distance $r$ from all three sides of $\Delta$. Then the Hausdorff-fellow-traveling condition (Lemma 4.8) will imply that $\Delta$ is $D_{4.8}(C, K, 2 r)$-thin.

Case 1: Suppose all three paths are of type 2. Then we replace $x, y, z$ by their $\rho$ projections to $A$ : The points $\bar{x}, \bar{y}, \bar{z}$ respectively. The subtriangle in $\Delta=c(x, y) \cup c(y, z) \cup$ $c(z, x)$ which is the union $\bar{\Delta}=c(\bar{x}, \bar{y}) \cup c(\bar{y}, \bar{z}) \cup c(\bar{z}, \bar{x}) \subset A$ is $\delta_{\mathfrak{Q}}$-hyperbolic, where $\delta_{\mathfrak{Q}}$ (depending only on $K$ and $C$ ) is a uniform bound on the hyperbolicity constant of the carpet $\mathfrak{A}$ (Proposition 4.1). Thus, $\Delta^{\prime}$ is $r=\delta_{\mathfrak{G}}$-thin, therefore, as we noted above, $\Delta$ itself is $D_{4.8}(C, K, 2 r)$-slim.

Case 2: Suppose we have a triangle $\Delta$ formed by three paths exactly two of which are of type 2 ; say, $c(x, y), c(y, z)$ are of type 2 and $c(x, z)$ is of type 1 . Since $c(x, z)$ has type 1 , the vertex $t=t_{x z}$ satisfies the inequalities

$$
d_{T}(\pi(x), \pi(\bar{x})) \geq d_{T}(\pi(x), t), \quad d_{T}(\pi(z), \pi(\bar{z})) \geq d_{T}(\pi(z), t)
$$

Thus, we can replace the points $x, z$ by $x^{\prime}:=\gamma_{x}(t)$ and $z^{\prime}:=\gamma_{z}(t)$ respectively (as they belong to $c(x, y)$ and $c(z, y)$ respectively). Now, by the definition of $t=t_{x z}, d\left(x^{\prime}, z^{\prime}\right) \leq$ $d_{X_{t}}\left(x^{\prime}, z^{\prime}\right) \leq M_{\bar{K}}$. Hence, the subtriangle $\Delta^{\prime} \subset \Delta$ formed by the paths $c\left(x^{\prime}, y\right), c^{\prime}\left(y, z^{\prime}\right), c\left(z^{\prime}, x^{\prime}\right)$ is $r=M_{\bar{K}}$-thin, which, in turn, implies that $\Delta$ is $D_{4.8}(C, K, 2 r)$-slim.

Figure 15. Three centers

Case 3: Suppose we have a triangle $\Delta$ formed by three paths exactly one which, say, $c(x, y)$ is of type 2. After swapping $x$ and $y$ we can assume that on the interval $\llbracket u, \pi(z) \rrbracket$ the
following vertices appear in this order:

$$
u \leq \pi(\bar{z}) \leq t_{y z} \leq t_{x z} \leq \pi(z)
$$

(Since $c(y, z), c(z, x)$ are of type 1 , the vertex $\pi(\bar{z})$ is closer to $u$ than both $t_{y z}, t_{x z}$.) As in Case 2, for $t=t_{x, z}$ we replace $x, z$ by the points

$$
x^{\prime}:=\gamma_{x}(t), \quad z^{\prime}:=\gamma_{z}(t)
$$

respectively. This defines a subtriangle $\Delta^{\prime} \subset \Delta$ formed by the paths $c\left(x^{\prime}, y\right), c\left(y, z^{\prime}\right)$, $c\left(z^{\prime}, x^{\prime}\right)$. By the definition of type 1 paths, $d_{X_{t}}\left(x^{\prime}, z^{\prime}\right) \leq M_{\bar{K}}$. Thus, again, the subtriangle $\Delta^{\prime} \subset \Delta$ is $r=M_{\bar{K}^{\prime}}$-thin and, therefore, $\Delta$ is $D_{4.8}(C, K, 2 r)$-slim.

Case 4: Suppose all three paths $c(x, y), c(y, z), c(z, x)$ forming a triangle $\Delta$ are of type 1. This is the most interesting of the four cases.

Without loss of generality we may assume that in the tree $T$,

$$
(\pi(x) \cdot \pi(y))_{u} \leq(\pi(y) \cdot \pi(z))_{u}
$$

In particular,

$$
b_{x, y}=b_{x, z}
$$

see Figure 15.

Figure 16. Triangles $\Delta, \Delta^{\prime}$
Consider the points

$$
x^{\prime} \in c(x, z) \cap X_{b_{x, z}}, y^{\prime} \in c(x, y) \cap X_{b_{x, y}}, z^{\prime} \in c(x, z) \cap X_{b_{y, z}}
$$

which are closest to, respectively, $x, y, z$ along the above paths, see Figure 16. The point $z^{\prime}$ then equals the point of the intersection

$$
c(y, z) \cap X_{b_{y, z}}
$$

which is closest to $z$ along the path $c(y, z)$.

Moreover, again by the definition of the paths $c$, the triangle $\Delta:=c(x, y) \cup c(y, z) \cup$ $c(z, x)$ is obtained from $\Delta^{\prime}:=c\left(x^{\prime}, y^{\prime}\right) \cup c\left(y^{\prime}, z^{\prime}\right) \cup c\left(z^{\prime}, x^{\prime}\right)$ by attaching (to its vertices) the following segments of the $K$-flow-lines:

$$
\gamma_{x, x^{\prime}} \subset \gamma_{x}, \gamma_{y, y^{\prime}} \subset \gamma_{y}, \gamma_{z, z^{\prime}} \subset \gamma_{z}
$$

Hence, the $r$-slimness of the triangle $\Delta^{\prime}$ will imply $r$-slimness of the triangle $\Delta$.
Thus, after replacing $x \rightarrow x^{\prime}, y \rightarrow y^{\prime}, z \rightarrow z^{\prime}$, it suffices to consider the case when $v^{\prime}=\pi(x)=\pi(y)$ and $v^{\prime} \in \llbracket u, \pi(z) \rrbracket$. Below, we will not be using the property that $\pi(x)=$ $\pi(y)$, only that all three projections $\pi(x), \pi(y), \pi(z)$ belong to a common oriented interval $J=\llbracket u, u^{\prime} \rrbracket \subset T$. Therefore,

$$
\left\{t_{z y}, t_{y x}, t_{x z}\right\} \subset J
$$

After a permuting the points $x, y, z$, we can assume that

$$
t_{z y} \leq t_{y x} \leq t_{x z}
$$

on the oriented interval $J$. Therefore, all three paths $\gamma_{x}, \gamma_{y}, \gamma_{z}$ contains the subpaths $\gamma_{x x^{\prime \prime}}, \gamma_{y y^{\prime \prime}}, \gamma_{z z^{\prime \prime}}$ with $x^{\prime \prime}, y^{\prime \prime}, z^{\prime \prime} \in X_{t}, t=t_{x z}$ and these subpaths are in the respective sides $c(x, y), c(y, z), c(z, x)$ of $\Delta$, see Figure 17.

Figure 17. Triangles $\Delta^{\prime}, \Delta^{\prime \prime}$.

Thus, we perform one more reduction, replacing the triangle $\Delta$ with the subtriangle $\Delta^{\prime \prime}$ formed by the paths $c\left(x^{\prime \prime}, y^{\prime \prime}\right), c\left(y^{\prime \prime}, z^{\prime \prime}\right), c\left(z^{\prime \prime}, x^{\prime \prime}\right)$, such that $x^{\prime \prime}, y^{\prime \prime}, z^{\prime \prime} \in X_{t}, t=t_{x z}$. By the definition of the vertex $t_{x z}$,

$$
d_{X_{t}}\left(x^{\prime \prime}, z^{\prime \prime}\right) \leq M_{\bar{K}}
$$

Thus, the triangle $\Delta^{\prime \prime}$ is $M_{\bar{K}} / 2$-thin, which concludes the proof in Case 4. This also completes the proof of Theorem 4.6.

Remark 4.10. Since the paths $c(x, y)$ are uniformly proper (Corollary 4.9), by Part (b) of Corollary 1.64, up to a reparameterization, they are uniform quasigeodesics in $L_{K}(\alpha)$.

### 4.3. Hyperbolicity of general ladders

In this section we prove that all ladders contained in $X$ are uniformly hyperbolic. The idea is to decompose the given ladder as a union of subladders, each of which is carpeted and then make use of the quasiconvex chain-amalgamation, Theorem 2.59.

We define $\bar{K}$ and $\kappa$ as in the previous section, Definition 4.5, (4.1) and (4.2). Recall that each $K$-ladder comes equipped with a family of $K$-sections $\Sigma_{\text {. }}$. These are the sections which will be used in the next proposition.

Proposition 4.11 (Vertical subdivision of general ladders). Fix numbers $K$ and $C$ such that $M_{\bar{K}} \leq C$, and suppose that $\mathfrak{X}$ satisfies the uniform $\kappa$-flaring condition. Consider a $(K, D, E)$-ladder ${ }^{2} \mathfrak{Z}=\mathfrak{L}_{K}(\alpha)$ over a subtree $S \subset T$, where $\alpha=\left[x_{u} y_{u}\right]_{X_{u}}$.

Then the geodesic segment $\alpha$ can be subdivided into subsegments $\alpha_{1}, \ldots, \alpha_{n}$ of lengths $l_{1}, \ldots, l_{n}$, with the end-points $x_{0}=x_{u}, x_{1}, \ldots, x_{n}=y_{u}$ such that the following hold:
(1) The $K$-qi sections $\Sigma_{x_{i}} \subset L=L_{K}(\alpha)$ through the points $x_{i}$ for $i=0, \ldots, n$, are such that each pair $\left(\Sigma_{x_{i}}, \Sigma_{x_{i+1}}\right)$, $i=0, \ldots, n-1$, bounds a $(K, D, E)$-subladder $\mathfrak{L}^{i}=\mathfrak{L}_{K, D, E}\left(\alpha_{i}\right) \subset \mathfrak{L}$. These subladders satisfy

$$
L^{i} \cap L^{i+1}=\Sigma_{x_{i}} .
$$

(2) Each ladder $\mathfrak{Q}^{i}, i=0, \ldots, n-1$, contains $a(K, C)$-narrow carpet $\mathfrak{Y}^{i}=\mathfrak{A}_{K}\left(\alpha_{i}^{\prime}\right)$, where $\alpha_{i}^{\prime} \subset \alpha_{i}$ contains $x_{i}$ and

$$
0 \leq l_{i}-\text { length }\left(\alpha_{i}^{\prime}\right) \leq M_{K} \leq M_{\bar{K}}
$$

if $i<n-1$, while $\alpha_{n}^{\prime}=\alpha_{n}$.
(3) $N_{C / 2}^{f i b}\left(\mathcal{L}^{i}\right) \cap N_{C / 2}^{f i b}\left(\mathcal{L}^{j}\right)=\emptyset$ provided that $|i-j|>1$.
(4) In each ladder $\mathfrak{L}^{i}$, the pair of sections $\left(\Sigma_{x_{i}}, \Sigma_{x_{i+1}}\right)$ is $B=B_{4.11}(K, C)$-cobounded, for $i=0, \cdots, n-2$. Moreover, the projection of $\Sigma_{x_{i+1}}$ to $\Sigma_{x_{i}}$ is uniformly close to the point $x_{w_{i}}$, where

$$
\left[x_{w_{i}} y_{w_{i}}\right]_{X_{w_{i}}}=A_{w_{i}}
$$

is the narrow end of the carpet $\mathfrak{\mathfrak { H } ^ { i } \text { . }}$
Proof. We will orient the interval $\alpha$ from $x_{u}$ to $y_{u}$ and, will use the corresponding natural order on $\alpha$.

Suppose $x_{j} \in \alpha$ have been chosen and $x_{i}<y$. To choose $x_{i+1}$ consider the subset

$$
\Omega_{i+1}:=\left\{x \in \alpha, x>x_{i}: d_{X_{b}}\left(\Sigma_{x} \cap \mathcal{L}_{b}, \Sigma_{x_{i}} \cap \mathcal{L}_{b}\right)>C, \forall b \in V\left(\pi\left(\Sigma_{x}\right) \cap \pi\left(\Sigma_{x_{i}}\right)\right)\right\} .
$$

In other words, $\Omega_{i+1}$ consists of points $x>x_{i}$ in $\alpha$ such that the sections $\Sigma_{x}$ and $\Sigma_{x_{i}}$ are fiberwise $C$-separated.

Now there are two possibilities. If $\Omega_{i+1}=\emptyset$ then define $n=i+1, x_{i+1}=y_{u}$. This will conclude the induction.

Otherwise, pick $x_{i+1} \in \Omega_{i+1}$ such that

$$
x_{i+1}-\inf \left(\Omega_{i+1}\right)<M_{K} / 2
$$

According to Corollary 3.12, $\Sigma_{x_{i}}, \Sigma_{x_{i+1}}$ bound a $(K, D, E)$-subladder $\mathfrak{Q}^{i}:=\mathfrak{L}_{K, D, E}\left(\alpha_{i}\right) \subset$ $\mathfrak{Z}$, where $\alpha_{i}=\left[x_{i} x_{i+1}\right]_{X_{u}} \subset \alpha$. By the construction, $L^{i} \cap L^{i-1}=\Sigma_{x_{i}}$.

In order to construct a $(K, C)$-narrow carpet $\mathfrak{A}^{i}=\mathfrak{H}_{K}\left(\alpha_{i}^{\prime}\right) \subset \mathfrak{L}^{i}$, we take a subsegment $\alpha_{i}^{\prime}=\left[x_{i} x_{i+1}^{\prime}\right]_{X_{u}} \subset \alpha_{i}=\left[x_{i} x_{i+1}\right]_{X_{u}}$ such that

$$
x_{i+1}^{\prime} \notin \Omega_{i+1}, d_{X_{u}}\left(x_{i+1}^{\prime}, x_{i+1}\right)<M_{K} .
$$

[^12]Since $x_{i+1}^{\prime} \notin \Omega_{i+1}$, by the definition of $\Omega_{i+1}$, the sections $\Sigma=\Sigma_{x_{i}}, \Sigma^{\prime}=\Sigma_{x_{i+1}^{\prime}}$ contain points $y, y^{\prime} \in X_{w}$ (for some $w \in V(S)$ ), such that

$$
d_{X_{w}}\left(y, y^{\prime}\right) \leq C
$$

Among such vertices $v \in T$ we choose one which is closest to $u$ (there might be several).
The $K$-sections $\Sigma, \Sigma^{\prime}$ contain subsections $\gamma_{y}, \gamma_{y^{\prime}}$ (over the interval $\left.\llbracket u, v \rrbracket\right)$ connecting $y, y^{\prime}$ to $x_{i}, x_{i+1}^{\prime}$ respectively.

Since $M_{K} \leq C$ and $w$ was chosen to be closest to $u$, we have that for every vertex $t \in \llbracket u, v \llbracket$,

$$
d_{X_{t}}\left(\gamma_{y}(t), \gamma_{y^{\prime}}(t)\right)>C \geq M_{K} .
$$

Thus, the sections $\gamma_{y}, \gamma_{y}^{\prime}$ form the top and the bottom of a $C$-narrow $K$-carpet $\mathfrak{A}_{K, C}\left(\alpha_{i}^{\prime}\right)$ in $\mathfrak{L}^{i}$ with the narrow end $\beta_{i}=L_{w} \cap \mathfrak{A}^{i}$.

This proves parts 1 and 2 of the proposition.
We next prove part 3. Suppose that $i+1<j$. By the construction, for each vertex $v \in \pi\left(\mathcal{L}^{i}\right) \cap \pi\left(\mathcal{L}^{j}\right)$ the length of the subsegment in $\mathcal{L}_{v}$ between $\Sigma_{x_{i+1}}, \Sigma_{x_{j}}$ is $>C$. Hence, the minimal fiberwise distance between $\mathcal{L}^{i} \cap X_{v}, \mathcal{L}^{j} \cap X_{v}$ is $>C$ as well. Part 3 follows since $\mathcal{L}_{v}$ is a geodesic segment in $X_{v}$.

Finally to prove (4) we will use the description of the paths $c(x, y)$ constructed for the proof Theorem 4.6 which are uniform quasigeodesics in the subladder $L^{i}=L_{K}\left(\alpha_{i}\right)$.

First of all, we observe that, the difference in the lengths of $\alpha_{i}^{\prime}, \alpha_{i}$ is at most $M_{K}$ and $\alpha_{i}^{\prime}$ bounds a $(K, C)$-narrow carpet $\mathfrak{A}^{i}$ in $\mathfrak{L}^{i}$. In other words, $\mathfrak{L}^{i}$ is a carpeted ladder and Theorem 4.6 applies in our case.

The carpet $\mathfrak{M}^{i}=\left(\pi: A^{i} \rightarrow \llbracket u, w_{i} \rrbracket\right)$ is bounded by horizontal paths $\gamma_{i} \subset \Sigma_{x_{i}}, \gamma_{i}^{\prime} \subset \Sigma_{x_{i+1}^{\prime}}$ and the vertical paths $\alpha_{i}^{\prime}, \beta_{i}$ (where $\beta_{i}$ has length $\leq C$ ).

Consider points $z_{i} \in \Sigma_{x_{i}}$ and $z_{i+1} \in \Sigma_{x_{i+1}}$. Since the fiberwise vertical separation between $\Sigma_{x_{i}}$ and $\Sigma_{x_{i+1}}$ is $>C \geq M_{\bar{K}}$, we conclude that the path $c\left(z_{i}, z_{i+1}\right)$ has to be of type 2 in the terminology of the proof Proposition 4.6.

In other words, $c\left(z_{i}, z_{i+1}\right)$ is the concatenation of five (actually, four) subpaths: Two of these subpaths (containing $z_{i}, z_{i+1}$ respectively, connect $z_{i}$ to $\tilde{z}_{i}, z_{i+1}$ to $\tilde{z}_{i+1}$ and are contained in, respectively, $\gamma_{i}, \gamma_{i+1}$. The point $\tilde{z}_{i+1}$ is within vertical distance $\leq M_{\bar{K}}$ from a point $\bar{z}_{i+1} \in \operatorname{top}\left(\mathfrak{H}^{i}\right)$, while the point $\tilde{z}_{i}$ actually equals $\bar{z}_{i}$. The vertical geodesic

$$
\left[\bar{z}_{i+1} \tilde{z}_{i+1}\right]_{L_{i+1}}, v_{i}=\pi\left(\tilde{z}_{i+1}\right)
$$

is contained in $c\left(z_{i}, z_{i+1}\right)$. The path $c\left(z_{i}, z_{i+1}\right)$ contains one more subpath, namely,

$$
c_{2 i} i\left(\bar{z}_{i}, \bar{z}_{i+1}\right)
$$

a path in the combing of $A^{i}$ constructed in the proof of Proposition 4.1. By the construction of $\mathfrak{A}^{i}$, each vertex-space $A_{v}$ of $\mathfrak{A}^{i}$ has length $\geq C \geq M_{\bar{K}}>M_{K}$. Thus, by the definition of $c_{2 i}\left(\bar{z}_{i}, \bar{z}_{i+1}\right)$ in the proof of Proposition 4.1 this path is a concatenation of subpaths contained in the top and the bottom of $\mathfrak{A}^{i}$ and, most importantly, the narrow end $\beta_{i}=\left[x_{w_{i}} y_{w_{i}}\right]_{w_{w_{i}}}$.

In particular, each uniform quasigeodesic path $c\left(z_{i}, z_{i+1}\right)$ contains the point $x_{i}^{-}:=x_{w_{i}} \in$ $A_{w_{i}}^{i} \cap \Sigma_{x_{i}}$

According to Lemma 1.98, it follows that the nearest-point projections (taken in $L^{i}$ ) of $\Sigma_{x_{i+1}}$ to $\Sigma_{x_{i}}$ is contained in the $R$-neighborhoods of $x_{w_{i}}$, where $R=R(K, C)$. Hence, by Corollary 1.140, the pair of sections $\Sigma_{i}, \Sigma_{i+1}$ is $B(K, C)$-cobounded in $L^{i}$. This concludes the proof of the proposition.

In Section 7.1 (when describing uniform quasigeodesics in ladders) we will need a bit more detailed information about the uniformly cobounded pair $\left(\Sigma_{x_{i}}, \Sigma_{x_{i+1}}\right)$. Let $x_{i}^{-} \in$
$\Sigma_{x_{i}}, x_{i}^{+} \in \Sigma_{x_{i+1}}$ be a pair of points realizing the minimal distance between these subsets in the ladder $L^{i}$. According to Part (4) of the proposition, $x_{i}^{-}$is uniformly close (in terms of $K$ and $C$ ) to the point $x_{w_{i}}$. We will also need to identify the other point, $x_{i}^{+}$, up to a uniformly bounded error.

Let $u_{i+1} \in \llbracket u, w_{i+1} \rrbracket$ benote the maximum (in the oriented interval $\left.\llbracket u, w_{i+1} \rrbracket\right)$ of the subset

$$
\left.\left\{t \in V\left(\llbracket u, w_{i+1} \rrbracket\right): d_{X_{t}}\left(\Sigma_{x_{i+1}} \cap X_{t}\right), A_{t}\right) \leq M_{\bar{K}}\right\} .
$$

For each vertex $v \in \llbracket u, u_{i+1} \rrbracket$ we observe that the top-most point $y_{v}^{\prime}$ of the segment $A_{v}$ divides $L_{v}^{i}$ in two subsegments:

$$
A_{v} \cup A_{v}^{\prime}, \quad A_{v}^{\prime}=\left[y_{v}^{\prime} y_{v}\right]_{X_{v}}
$$

where

$$
y_{v}=\operatorname{top}\left(L_{v}^{i}\right) .
$$

The first part of the next lemma will be used in Section 7.1, while second part will be used in Section 8.3 (proof of Lemma 8.28).

Lemma 4.12. 1 .

$$
d\left(y_{u_{i+1}}, x_{i}^{+}\right) \leq D_{4.12}(K, C) .
$$

2. For each $v$ as above, the length of $A_{v}^{\prime}$ is $\leq R_{4.12}(K)$.

Proof. 1. Take a point $y \in \Sigma_{x_{i+1}} \cap X_{v}$. Then, as we noted in the proof of the last part of the proposition, since each path $c(x, y)$ connecting (any) $x \in \Sigma_{x_{i}}$ to $y$ has type 2 , it has to pass through a point of the segment $A_{u_{i+1}}^{\prime}$, and the latter has length $\leq M_{\bar{K}}$. Thus, $c(x, y)$ passes within distance $M_{\bar{K}}$ from $y_{u_{i+1}}$. It follows that $d\left(y_{u_{i+1}}, x_{i}^{+}\right)$is uniformly bounded in terms of $K$ and $C$.
2. This part is an application of uniform flaring. We have two $K$-qi sections $\gamma_{0}, \gamma_{1}$ over the interval $J=\llbracket u, u_{i+1} \rrbracket$, defined by restricting $\operatorname{top}\left(\mathfrak{A}^{i}\right)$ and $\Sigma_{i+1}$. The vertical separation between these sections at the end-points of $J$ is $\leq M_{\bar{K}}$. Thus, by Corollary 2.49, the vertical separation between these sections elsewhere in the interval is $\leq \tau_{2.49}\left(K, M_{\bar{K}}\right)$. Hence, we can take

$$
R_{4.12}(K)=\tau_{2.49}\left(K, M_{\bar{K}}\right)
$$

Theorem 4.13. For each $K$ and a hyperbolic tree spaces $\mathfrak{X}$ satisfying the uniform $\kappa=\kappa_{4.5}(K)$-flaring assumption as in Proposition 4.6, and arbitrary $D$ and $E$, there exists $\delta=\delta_{4.13}(K)$ such that every $(K, D, E)$-ladder $\mathfrak{Z}=\mathfrak{L}_{K}(\alpha) \subset \mathfrak{X}$ has $\delta$-hyperbolic total space $L$ with respect to the intrinsic metric of the ladder.

Proof. Set $C=M_{\bar{K}}$. By Proposition 4.11 we have a subdivision $x_{0}=x_{u}, x_{1}, \ldots, x_{n}=y_{u}$ of the segment $\alpha=\left[x_{u} y_{u}\right]_{X_{u}}$. The $K$-qi sections $\Sigma_{i}:=\Sigma_{x_{i}}$ in $\mathbb{L}$ passing through $x_{i}$ 's decompose the ladder $\mathfrak{L}$ into subladders $\mathfrak{L}^{i}:=\mathfrak{L}_{K}\left(\left[x_{i-1} x_{i}\right]_{X_{u}}\right)$ containing $(K, C)$-narrow carpets $\mathfrak{A}^{i}$. Hence, by Proposition 4.6, each $L^{i}$ (the total space of $\mathfrak{Q}^{i}$ ) is $\delta_{4.6}(K, C)$-hyperbolic. By the construction,

$$
L^{i} \cap L^{i+1}=\Sigma_{i}, i=1, \ldots, n-1
$$

The subsets $\Sigma_{i}$ are $K$-sections, hence, are $\lambda_{1.90}\left(\delta_{4.6}(K, C), K\right)$-quasiconvex in $L^{i}, L^{i+1}$. Furthermore, by Proposition 4.11, each pair of ladders $\mathfrak{L}^{i-1}, \mathfrak{L}^{i+1}, i \geq 1$, is $B_{4.11}(K, C)$-cobounded. Thus, arbitrary ladder $L=L_{K}(\alpha)$ is uniformly hyperbolic by Theorem 2.59.

## CHAPTER 5

## Hyperbolicity of flow-spaces

In this chapter we shall prove that the $k$-flow-spaces (for $k$ in a suitable range) of each vertex space $X_{u} \subset X$, are uniformly hyperbolic (with hyperbolicity constant depending on $k$ ) provided that $\mathfrak{X}$ is a hyperbolic tree of spaces satisfying a certain uniform flaring condition. The strategy of the proof is to show that:
(a) Every two points $x, y$ in $F l_{k}\left(X_{u}\right)$ belong to a common a ladder ( $K, D, E$ )-ladder $L_{x, y}$ (essentially contained in $F l_{k}\left(X_{u}\right)$ ), where $D$ is a sufficiently large number, $K$ depends only on $k$ and $E$ depends on $k$ and $D$. This is done in Section 5.1. Actually, in Section 5.1 we prove a stronger result, the existence of tripods of ladders connecting points $x_{1}, x_{2}, x_{3} \in F l_{k}\left(X_{u}\right)$ such that in each vertex-space of $\mathfrak{F} l_{k}\left(X_{u}\right)$ the three geodesics of these ladders form a geodesic tripod. Hyperbolicity of total spaces of such tripods of ladders is almost immediate, Section 5.3.
(b) Since ladders are uniformly hyperbolic (as it was proven in the previous chapter), this appears to yield a preferred family of paths $c(x, y)$ connecting points of $F l_{k}\left(X_{u}\right)$ (projections of uniform quasigeodesics in corresponding ladders). Hyperbolicity of tripods of ladders should then yield the uniform slimness condition for the family of paths $c(x, y)$. The trouble, however, is that $L_{x, y}$ is far from canonical, and, thus, it is far from clear why the paths $c(x, y)$ satisfy the fellow-traveling condition. If different ladders $L_{x, y}^{1}, L_{x, y}^{2}$ were at uniformly bounded minimal distance from each other in each fiber-space where both ladders are nonempty, one could use hyperbolicity of the union of these two ladders. Unfortunately, it is unclear why there should be a uniform bound on such minimal distance. To resolve the problem, we use the construction of a coarse projection of the ladder $L_{x, y}^{1}$ to $L_{x, y}^{2}$ defined in Section 5.2. This projection is used in Proposition 5.18 to construct a uniformly hyperbolic subspace $Z$ in $X$ containing the two ladders. The coarse independence of the paths $c(x, y)$ on the choice of $L_{x, y}$ is then almost immediate, Corollary 5.19.

This, in turn, will conclude the verification of hyperbolicity of flow-spaces, Theorem 5.17.

### 5.1. Ubiquity of ladders in $F l_{k}\left(X_{u}\right)$

In this section we prove that for all (sufficiently large) $D$ and $k$, and all $x, y \in F l_{k}\left(X_{u}\right)$, there is a $(K, D, E)$-ladder $\mathfrak{L}$ containing $x, y$, where $K=K(k), E=3 k+D$. Furthermore, $\mathfrak{L}$ will be contained in the fiberwise $4 \delta_{0}$-neighborhood of $\mathfrak{F} l_{K}\left(X_{u}\right)$. We will actually prove a stronger result, about the existence of a tripod of ladders containing given three points in $F l_{K}\left(X_{u}\right)$.

In the next definition and in what follows, $i$ is taken modulo 3 .
Definition 5.1. A ( $K, D, E$ )-tripod of ladders in $\mathfrak{X}$ is a semicontinuous $(K, D, E)$ family $\mathfrak{Y}$ over a subtree $S \subset T$, which is a union of three $(K, D, E)$-ladders $\mathfrak{Q}^{i}=\left(L^{i} \rightarrow\right.$ $\left.S_{i}\right), i=1,2,3$, such that:

1. There exists a $K$-section $\Xi$ defined over the subtree

$$
S_{123}:=S_{1} \cap S_{2} \cap S_{3}
$$

and called the center-section of $\mathfrak{Y}$, such that for each $v \in V\left(S_{123}\right)$ and $i \in\{1,2,3\}, \Xi(v)=$ top $\left(\mathcal{L}^{i}\right) \cap X_{v}$.
2. For each $v \in V\left(S_{123}\right), e \in E\left(S_{123}\right)$, the vertex- and edge-space $Y_{v}, Y_{e}$ of $\mathfrak{Y}$ is a $\delta_{0}$-tripod in $X_{v}, X_{e}$

$$
Y_{v}=\bigcup_{i=1}^{3}\left[x_{v}^{i} z_{v}\right]_{X_{v}}, Y_{e}=\bigcup_{i=1}^{3}\left[x_{e}^{i} z_{e}\right]_{X_{e}}, z_{v}=\Xi(v), L_{v}^{i}=\left[x_{v}^{i} z_{v}\right]_{X_{v}}, L_{e}^{i}=\left[x_{e}^{i} z_{e}\right]_{X_{e}} .
$$

3. If $v \in V\left(S_{i}\right) \backslash V\left(S_{123}\right)$, then $L_{v}^{i+1}=L_{v}^{i-1}=\emptyset$ (two legs of the tripod are missing) and $L_{v}^{i}=L_{v}=\left[x_{v} y_{v}\right]_{X_{v}}$ (we, thus, omit the superscript $i$ in this situation). The same applies to the edges.

We will refer to the union of bottoms of the ladders $\mathfrak{L}^{i}$ as the bottom (denoted $\left.\operatorname{bot}(\mathfrak{Y})\right)$ ) of the tripod of ladders $\mathfrak{Y}$.

A tripod of ladders $\mathfrak{Y}$ is said to be degenerate if for some $i \in\{1,2,3\}$, $\mathfrak{Q}^{i+1}=\mathfrak{Q}^{i-1}=\Xi$ and, thus, $\mathfrak{V}$ ) is reduced to a single ladder, $\mathfrak{L}^{i}$.

In the following proposition, $D_{0}=D_{1.139}\left(\delta_{0}^{\prime}, \lambda_{0}^{\prime}\right)$,

$$
\begin{gather*}
C=2\left(\lambda_{0}^{\prime}+2 \delta_{0}^{\prime}+D_{1.53}\left(\delta_{0}^{\prime}, L_{0}^{\prime}\right)\right)+C_{1.107}\left(\delta_{0}^{\prime}, \lambda_{0}^{\prime}\right), \\
D_{1}:=\max \left(D_{0}, C_{1.140}\left(\lambda_{0}^{\prime}, \delta_{0}^{\prime}, C\right)\right) \\
D=D_{5.2}:=D_{1}+\max \left(3 \delta_{0}, 2 \delta_{0}+2\left(\lambda_{0}^{\prime}+2 \delta_{0}^{\prime}\right)\right) \tag{5.1}
\end{gather*}
$$

Assume also that $k=r^{\wedge}=\left(15 L_{0}^{\prime} r\right)^{3} \geq K_{0}$ and $r$ satisfies the inequality

$$
r \geq r_{1}=\max \left(2 \lambda_{0}^{\prime}+5 \delta_{0}^{\prime}, \lambda+4 \lambda_{0}^{\prime}+8 \delta_{0}^{\prime}+5 \delta_{0}\right)
$$

where

$$
\lambda=C_{1.125}\left(\delta_{0}^{\prime}, \lambda_{0}^{\prime}, L_{0}^{\prime}\right)
$$

In other words,

$$
\begin{equation*}
k \geq k_{5.2}=K_{1}:=\max \left(K_{0},\left(15 L_{0}^{\prime} r_{1}\right)^{3}\right) \tag{5.2}
\end{equation*}
$$

Note that, in particular, $k \geq \lambda+4 \lambda_{0}^{\prime}+8 \delta_{0}^{\prime}+5 \delta_{0}$.
In the proposition we will be also using the function $\kappa^{\prime}=K_{3.17}^{\prime}(\kappa)$ defined in Lemma 3.17.

Proposition 5.2 (Existence of tripods of ladders). Let $\mathfrak{X}=(\pi: X \rightarrow T)$ be a tree of spaces satisfying Axiom H1. Then for $k$ and $D$ as above, there exist constants

$$
K=K_{5.2}(k), E=E_{5.2}(k)
$$

such that the following holds.
For points $x^{i}, i=1,2,3$ in $\mathcal{F} l_{k}\left(X_{u}\right)$, we let $\gamma^{i}:=\gamma_{x^{i}}$ denote $k$-sections in $F l_{k}\left(X_{u}\right)$ over $\llbracket u, \pi\left(x^{i}\right) \rrbracket$, connecting $x^{i}$ to $X_{u}$.

Then:
(i) There exists a $(K, D, E)$-tripod of ladders $\mathfrak{Y}=\mathfrak{Q}^{1} \cup \mathfrak{Q}^{2} \cup \mathfrak{Q}^{3}$, centered at u such that:

1. $\boldsymbol{y} \subset N_{5 \delta_{0}}^{f i b} \mathcal{F} l_{k}\left(X_{u}\right)$, while $\operatorname{bot}(\boldsymbol{Y}) \subset \mathcal{F} l_{k}\left(X_{u}\right)$.
2. $\gamma^{i} \subset \operatorname{bot}\left(\mathfrak{Q}^{i}\right), i=1,2,3$, thus, $\gamma^{i} \subset \operatorname{bot}(\mathfrak{Y})$.
3. If, for some $i$, $\gamma^{i-1}=\gamma^{i+1}$, then the tripod of ladders $\mathfrak{Y}$ is degenerate and the section $\gamma^{i-1}=\gamma^{i+1}$ is contained in the center-section $\Xi$ of $\mathfrak{Y}$.
(ii) There exist $(K, D, E)$-ladders $L^{i j}$ containing $x^{i}, x^{j}$, such that top $\left(L^{i j}\right) \subset \operatorname{bot}\left(L^{j}\right)$, $\operatorname{bot}\left(L^{i j}\right) \subset \operatorname{bot}\left(L^{j}\right)$, and $L^{i j}$ is contained in $\delta_{0}$-fiberwise neighborhood of $\mathfrak{Q}^{i} \cup \mathfrak{Q}^{j}$.

Proof. We first note that, according to Lemma 3.28, given $x \in F l_{k}\left(X_{u}\right)$, there exist a maximal $K$-section $\Sigma_{x} \subset F l_{k}\left(X_{u}\right)$ through $x$, intersecting $X_{u}$ and containing $\gamma_{x}$. Thus, we define the maximal $k$-sections $\Sigma_{x^{i}}, i=1,2,3$ through points $x^{i}$, intersecting $X_{u}$, and containing $\gamma^{i}$ (if it is given), otherwise, chosen arbitrarily. (Note that these sections $\Sigma_{x^{i}}$ need not be disjoint and, in general, they have different domains in $T$.) In line with Part 3 of the proposition, if $\gamma^{i-1}=\gamma^{i+1}$, we require $\Sigma_{x^{i-1}}=\Sigma_{x^{i+1}}$. We define tripods $Y_{v}, v \in V(T)$ inductively, by induction on the distance from $v$ to $u$.

As the base of induction, we define $x_{u}^{i}$ as $\gamma^{i}(u)$ and $L_{u}^{i}$ as a geodesic segment $\left[x_{u}^{i} z_{u}\right]_{X_{u}}$, where $z_{u}$ is a $\delta_{0}$-center of the geodesic triangle $\Delta_{u}=\Delta x_{u}^{1} x_{u}^{2} x_{u}^{3}$ in $X_{u}$.

We then proceed inductively as in the proof of Lemma 3.17 to which we refer the reader for the notation used below. Namely, assume that segments $L_{v}^{i}$ are defined for vertices of the subtree $B_{n} \subset T$,

$$
L_{v}^{i}=\left[x_{v}^{i} z_{v}\right]_{X_{v}}, v \in V\left(B_{n}\right), Y_{v}=L_{v}^{1} \cup L_{v}^{2} \cup L_{v}^{3},
$$

where $z_{v}$ is a $\delta_{0}$-center of the geodesic triangle $\Delta_{v}=\Delta x_{v}^{1} x_{v}^{2} x_{v}^{3}$. (In order to simplify the notation, we allow for empty vertex and edge-spaces in ladders.) We let $d_{Y_{v}}$ denote the intrinsic path-metric on $Y_{v}$. Then the inclusion map $\left(Y_{v}, d_{Y_{v}}\right) \rightarrow X_{v w}$ is an $L_{0}^{\prime}\left(2 \delta_{0}\right)$-qi embedding for each edge $[v, w] \in E(T), v \in B_{n}$, directed away from $u$. We will be also assuming (inductively) that the extremities $x_{v}^{i}$ of $Y_{v}$ belong to $Q_{v}=F l_{k}\left(X_{u}\right) \cap X_{v}$ and, thus, $Y_{v}$ is contained in the $5 \delta_{0}$-neighborhood of $Q_{v}$ taken in $X_{v}$.

Next, we apply the modified projection $\bar{P}_{X_{v w}, Y_{v}}$ to $X_{w}$. The image $\bar{Y}_{v}$ is the closed convex hull of $P_{X_{v w}, Y_{v}}\left(X_{w}\right)$ in the tripod $Y_{v}$ (with respect to the path-metric of $Y_{v}$ ). Specifically, if $\bar{Y}_{v} \neq \emptyset$, then it is the convex hull (taken in $Y_{v}$ ) of three points $\bar{x}_{v}^{i}, i=1,2,3$, such that $\bar{x}_{v}^{i}$ is the nearest-point projection (taken in $\left(Y_{v}, d_{Y_{v}}\right)$ ) of $x_{v}^{i}$ to $\bar{Y}_{v}$.

Note that it is entirely possible for the center $z_{v}$ not to belong to $\bar{Y}_{v}$, in which case $\bar{Y}_{v}$ is a segment contained in the relative interior of one of the legs of $Y_{v}$. It even can happen that $\bar{Y}_{v}$ is empty, if $Q_{w}=\emptyset$. Our next task is to analyze implications of the containment $\bar{Y}_{v} \subset L_{v}^{i}$.

Lemma 5.3. Suppose that $\bar{Y}_{v}$ is contained in $L_{v}^{i}, d_{T}(u, v)=n$ and $e=[v, w]$ is an edge of $T$ oriented away from $u$. Then for $j=i \pm 1$ we have

$$
P_{X_{v w}, L_{v}^{j}}\left(X_{w}\right) \subset B^{e}\left(z_{v}, C\right)
$$

where $B^{e}\left(z_{v}, C\right)$ is the ball with respect to the metric of $X_{v w}$ and $C=C_{5.3}$.
Proof. According to Corollary 1.107, for the $\lambda_{0}^{\prime}$-quasiconvex subsets $V=L_{v}^{j}, U=Y_{v}$ in $X_{v w}$ we have

$$
d_{X_{v w}}\left(P_{X_{v w}, V}, P_{U, V} \circ P_{X_{v w}, U}\right) \leq C_{1.107}\left(\delta_{0}^{\prime}, \lambda_{0}^{\prime}\right)
$$

Here all the projections are taken with respect to the restriction of the metric on $X_{v w}$. Thus, we need to prove that $P_{U, V}\left(L_{v}^{i}\right)$ is uniformly close to the point $z_{v}$. This is obviously true for the intrinsic nearest-point projection $P_{U, V}^{\prime}\left(L_{v}^{i}\right)$ (taken with respect to the metric $d_{Y_{v}}$ ), since $P_{U, V}^{\prime}$ sends $L_{v}^{i}$ to $\left\{z_{v}\right\}$. Therefore, we need to compare the intrinsic projection $Y_{v} \rightarrow L_{v}^{j}$ and the extrinsic projection, with respect to the metric of $X_{v w}$.

Take some $x \in L_{v}^{i}$ and let $\bar{x}=P_{X_{v w}, V}(x)$. According to Lemma 1.102, the geodesic $\alpha^{*}=\left[x z_{v}\right]_{X_{v w}}$ passes within distance $\lambda_{0}^{\prime}+2 \delta_{0}^{\prime}$ from the point $\bar{x}$. Since the segment $\alpha=$ [ $\left.x z_{v}\right]_{X_{v}}$ is an $L_{0}^{\prime}$-quasigeodesic in $X_{v w}$, it follows that

$$
\operatorname{Hd}_{X_{v w}}\left(\alpha, \alpha^{*}\right) \leq D_{1.53}\left(\delta_{0}^{\prime}, L_{0}^{\prime}\right)
$$

Hence, $\alpha^{*}$ contains a point $y$ satisfying

$$
d_{X_{v w}}\left(y, z_{v}\right) \leq \lambda_{0}^{\prime}+2 \delta_{0}^{\prime}+D_{1.53}\left(\delta_{0}^{\prime}, L_{0}^{\prime}\right)
$$

Since

$$
d_{X_{v w}}(x, \bar{x}) \leq d_{X_{v v}}\left(x, z_{v}\right)
$$

we get

$$
d_{X_{v w}}\left(\bar{x}, z_{v}\right) \leq 2\left(\lambda_{0}^{\prime}+2 \delta_{0}^{\prime}+D_{1.53}\left(\delta_{0}^{\prime}, L_{0}^{\prime}\right)\right)
$$

Combining this estimate with Corollary 1.107, and the hypothesis that $P_{X_{v w}, U}\left(X_{w}\right) \subset L_{v}^{i}$, we conclude that for each point $q \in X_{w}, P_{X_{v v}, U}(q)=x \in L_{v}^{i}$ and

$$
\begin{array}{r}
d_{X_{v w}}\left(P_{X_{v w}, L_{v}^{\prime}}(q), z_{v}\right) \leq C_{5.3}:= \\
2\left(\lambda_{0}^{\prime}+2 \delta_{0}^{\prime}+D_{1.53}\left(\delta_{0}^{\prime}, L_{0}^{\prime}\right)\right)+C_{1.107}\left(\delta_{0}^{\prime}, \lambda_{0}^{\prime}\right) .
\end{array}
$$

Combining the lemma with Corollary 1.140, yields:
Corollary 5.4. If $\bar{Y}_{v}$ is contained in $L_{v}^{i}$, then for $j=i \pm 1$, the pair $\left(L_{v}^{j}, X_{w}\right)$ is $C_{1.140}\left(\lambda_{0}^{\prime}, \delta_{0}^{\prime}, C\right)$-cobounded in $X_{v w}$, where $C=C_{5.3}$.

Remark 5.5. The assumption $D \geq D_{1}$ made in the proposition ensures that $D \geq$ $C_{1.140}\left(\lambda_{0}^{\prime}, \delta_{0}^{\prime}, C\right)$. Thus, $\bar{Y}_{v} \subset L_{v}^{i}$ implies that the pair $\left(L_{v}^{j}, X_{w}\right)$ is $D_{1}$-cobounded in $X_{v w}$, hence, $D$-cobounded.

We now return to the construction of a family of tripods. Let $e=[v, w]$ be an edge directed away from $u, v \in B_{n} \subset T, w \notin B_{n}$. There are several things which can now happen, primarily depending on the coboundedness of $Y_{v}$ and $X_{w}$, but also on intersections of the sections $\Sigma_{x^{i}}$ with $X_{w}$.

Case 1: Suppose that the tripod $Y_{v}$ and $X_{w}$ are $D_{1}$-cobounded (in $X_{v w}$ ) and all three sections $\Sigma_{x^{i}}$ are disjoint from $X_{w}$. Then we set $Y_{w}=\emptyset$.

Remark 5.6. Observe that if the pair $\left(Y_{v}, X_{w}\right)$ is $D_{1}$-cobounded, so are the pairs $\left(L_{v}^{i}, X_{w}\right)$, $i=1,2,3$.

Case 2: Suppose that the tripod $Y_{v}$ and $X_{w}$ are not $D_{1}$-cobounded. We will also assume that the tripod $Y_{v}$ has "all its legs," i.e. $L_{v}^{i} \neq \emptyset, i=1,2,3$. According to Lemma 1.125,

$$
\begin{equation*}
\bar{Y}_{v} \subset N_{\lambda}\left(P_{X_{v w}, Y_{v}}\left(X_{w}\right)\right), \tag{5.3}
\end{equation*}
$$

where, as before,

$$
\lambda=C_{1.125}\left(\delta_{0}^{\prime}, \lambda_{0}^{\prime}, L_{0}^{\prime}\right) .
$$

We now use the fact that $D_{1} \geq D_{0}=D_{1.139}\left(\delta_{0}^{\prime}, \lambda_{0}^{\prime}\right)$. Since $Y_{v}$ and $X_{w}$ are not $D_{1}$-cobounded, by Corollary 1.143,

$$
P_{X_{v w}, Y_{v}}\left(X_{w}\right) \subset N_{4 \lambda_{0}^{\prime}+8 \delta_{0}^{\prime}}^{e}\left(X_{w}\right) \cap Y_{v}
$$

hence,

$$
\bar{Y}_{v} \subset N_{\lambda+4 \lambda_{0}^{\prime}+8 \delta_{0}^{\prime}}^{e}\left(X_{w}\right) \cap Y_{v}
$$

However, $Y_{v} \subset N_{5 \delta_{0}}^{f i b}\left(Q_{v}\right)$, by the inductive hypothesis. Hence, each point $x \in X_{w}$ within distance (in $X_{\nu w}$ )

$$
\lambda+4 \lambda_{0}^{\prime}+8 \delta_{0}^{\prime}+5 \delta_{0}
$$

from $\bar{Y}_{v}$, belongs to $Q_{w}^{\prime}=N_{r}^{e}\left(Q_{v}\right) \cap X_{w}, r=k^{\vee}$ (see the definition of flow-spaces in Section 3.3). Since, by the assumption of the proposition,

$$
k^{\vee}>\lambda+4 \lambda_{0}^{\prime}+8 \delta_{0}^{\prime}+5 \delta_{0}
$$

we see that

$$
\bar{Y}_{v} \subset N_{\lambda+4 \lambda_{0}^{\prime}+8 \delta_{0}^{\prime}}^{e}\left(Q_{w}\right) \cap Y_{v}
$$

Since the extremities $\bar{x}_{v}^{i}, i=1,2,3$, of the (possibly degenerate) tripod $\bar{Y}_{v}$ are at the distance $4 \lambda_{0}^{\prime}+8 \delta_{0}^{\prime}+5 \delta_{0}$ from $Q_{w}$, we take points $\tilde{x}_{w}^{i} \in Q_{w}$ which are nearest-point projections of $\bar{x}_{v}^{i}, i=1,2,3$, and, thus,

$$
\begin{equation*}
d_{X_{v w}}\left(\bar{x}_{v}^{i}, \tilde{x}_{w}^{i}\right) \leq 4 \lambda_{0}^{\prime}+8 \delta_{0}^{\prime}+5 \delta_{0} \tag{5.4}
\end{equation*}
$$

(If $\bar{x}_{v}^{i}=\bar{x}_{v}^{j}$ then $\tilde{x}_{w}^{i}=\tilde{x}_{w}^{j}$.) Similarly, if $z_{v}$ belongs to $\bar{Y}_{v}$ then there exists $\tilde{z}_{w} \in Q_{w}$ satisfying

$$
d_{X_{v w}}\left(z_{v}, \tilde{z}_{w}\right) \leq \lambda+4 \lambda_{0}^{\prime}+8 \delta_{0}^{\prime}+5 \delta_{0}
$$

In this case, we define the tripod $\tilde{Y}_{w} \subset X_{w}$ centered at $\tilde{z}_{w}$ and with the legs $\left[\tilde{z}_{w} \tilde{x}_{w}^{i}\right]_{X_{w}}$.
The actual tripod $Y_{w}$, as we will see, is uniformly Hausdorff-close to $\tilde{Y}_{w}$. For now, we observe that, according to Lemma 1.54:

$$
\begin{equation*}
\operatorname{Hd}_{X_{v w}}\left(\tilde{Y}_{w}, \bar{Y}_{v}\right) \leq D_{1.54}\left(\delta_{0}^{\prime}, L_{0}^{\prime}, 4 \lambda_{0}^{\prime}+8 \delta_{0}^{\prime}+5 \delta_{0}\right) \tag{5.5}
\end{equation*}
$$

Depending on the intersections $\Sigma_{x^{i}} \cap X_{w}$, the points $\tilde{x}_{w}^{i}$ might be the vertices of the tripod $Y_{w}$. Specifically, there are four subcases:
(a) If for some $i, \Sigma_{x^{i}} \cap X_{w}=\left\{x_{w}^{i}\right\}$, then we use the point $x_{w}^{i}$ as one of the vertices of $\Delta_{w}$. Thus,

$$
d_{X_{v w}}\left(x_{v}^{i}, x_{w}^{i}\right) \leq k
$$

in this subcase.
(b) If for some $i, \bar{Y}_{v}$ is disjoint from (necessarily both) $L_{v}^{i \pm 1}$ and $\Sigma_{x^{i+1}} \cap X_{w}=\emptyset, \Sigma_{x^{i-1}} \cap$ $X_{w}=\emptyset$, we set $L_{w}^{i \pm 1}=\emptyset$. Thus, in this subcase the tripod $Y_{w}$ will be missing two legs. This degenerate tripod will be equal the oriented geodesic segment $L_{w}^{i}=L_{w}=\left[x_{w} y_{w}\right]_{X_{w}}$, where $x_{w}=\tilde{x}_{w}^{i \pm 1}$ and $y_{w}$ will be either $\tilde{x}_{w}^{i}$ (if $\Sigma_{x^{i}} \cap X_{w}=\emptyset$ ) or, as in subcase (a), $\Sigma_{x^{i}} \cap X_{w}=\left\{y_{w}\right\}$. In this situation, by the construction, for

$$
\begin{gathered}
\hat{x}_{v}:=\bar{x}_{v}^{i \pm 1} \\
d_{X_{v w}}\left(x_{w}, \hat{x}_{v}\right) \leq 4 \lambda_{0}^{\prime}+8 \delta_{0}^{\prime}+5 \delta_{0}
\end{gathered}
$$

while

$$
d_{X_{v w}}\left(y_{w}, \hat{y}_{v}\right) \leq \max \left(k, 4 \lambda_{0}^{\prime}+8 \delta_{0}^{\prime}+5 \delta_{0}\right)=k
$$

Here $\hat{y}_{v}=\bar{x}_{v}^{i}$ (if $\Sigma_{x^{i}} \cap X_{w}=\emptyset$ ) or $\hat{y}_{v}=x_{v}^{i}$ (otherwise).
Remark 5.7. In this subcase, due to our assumptions on $D_{1}$, both pairs ( $L_{v}^{i \pm 1}, X_{w}$ ) will be $D_{1}$-cobounded, see Remark 5.5.
(c) If for some $i, \bar{Y}_{v}$ is disjoint from (necessarily both) $L_{v}^{i \pm 1}$ and for exactly one element $j \in\{i \pm 1\}$, the section $\Sigma_{x^{j}}$ intersects $X_{w}$, then we discard the point $\bar{x}_{v}^{i \pm 1}$ and let $z_{w}=x_{w}^{i-1}=$ $x_{w}^{i+1}$ be that point of intersection. We let $x_{w}^{i}$ either be equal to the intersection point of $\Sigma_{x^{i}}$ and $X_{w}$ (if the intersection is nonempty) or equal to $\tilde{x}_{w}^{i}$. Thus,

$$
d_{X_{v w}}\left(z_{w}, \bar{x}_{v}^{j}\right) \leq k
$$

while either

$$
d_{X_{v w}}\left(x_{w}^{i}, \hat{y}_{v}\right) \leq \max \left(4 \lambda_{0}^{\prime}+8 \delta_{0}^{\prime}+5 \delta_{0}, k\right)=k
$$

where, as in the subcase (b), $\hat{y}_{v}=\bar{x}_{v}^{i}$, or $\hat{y}_{v}=x_{v}^{i}$.
(d) In the "generic" case (i.e. when $z_{v} \in \bar{Y}_{v}$ ), for each $i$ such that $\Sigma_{x^{i}} \cap X_{w}=\emptyset$, we set $x_{w}^{i}=\tilde{x}_{w}^{i}$. (Of course, if $\Sigma_{x^{i}} \cap X_{w}$ is nonempty, we use this intersection point as $x_{w}^{i}$, see subcase (a).) As above, we obtain:

$$
d_{X_{v w}}\left(x_{w}^{i},\left\{\bar{x}_{v}^{i}, x_{v}^{i}\right\}\right) \leq \max \left(4 \lambda_{0}^{\prime}+8 \delta_{0}^{\prime}+5 \delta_{0}, k\right)=k, i=1,2,3 .
$$

Except for the subcase (b), we, thus, obtain three points $x_{w}^{1}, x_{w}^{2}, x_{w}^{3}$ spanning a (possibly degenerate) geodesic triangle $\Delta_{w}=\Delta x_{w}^{1} x_{w}^{2} x_{w}^{3} \subset X_{w}$. We let $z_{w}$ be a $\delta_{0}$-center of this triangle. (The subcase (c) above does not cause trouble because the triangle $\Delta_{w}$ is degenerate and one of its sides equals the point $z_{w}$, which is, therefore, the center of $\Delta_{w}$.) Accordingly, we define geodesic segments

$$
L_{w}^{i}:=\left[x_{w}^{i} z_{w}^{i}\right]_{X_{w}}
$$

and the tripod $Y_{w}=L_{w}^{1} \cup L_{w}^{2} \cup L_{w}^{3}$.
The subcase (b) requires a separate discussion since the tripod $Y_{w}$ is missing two out of its three legs. In this situation, by the definition of the point $x_{w}$,

$$
d_{X_{v w}}\left(x_{w}, \bar{x}_{v}^{i \pm 1}\right) \leq \lambda+4 \lambda_{0}^{\prime}+8 \delta_{0}^{\prime}+5 \delta_{0} \leq k
$$

by the assumption on $k$ made in the proposition.
Case 3. We still assume that $Y_{v}$ and $Q_{w}$ are not $D_{1}$-cobounded, but consider the case that $Y_{v}$ is degenerate and has only one leg, $L_{v}^{i}=L_{v}=\left[x_{v} y_{v}\right]_{X_{v}}$ : The other two legs are empty. We treat this case exactly the same way as we treated the subcases (2b) and (2c) above: The tripod $\bar{Y}_{v}$ has empty intersection with the empty legs $L_{v}^{i \pm 1}$ of $Y_{v}$. The points $x_{w}, y_{w} \in X_{w}$ define the oriented segment $L_{w}=\left[x_{w} y_{w}\right]_{X_{w}}$ and the points $x_{w}, y_{w}$ are within distance $k$, respectively, from points $\hat{x}_{v}, \hat{y}_{v}$, where (as in subcase (2b)) $\hat{x}_{v} \in\left\{\bar{x}_{v}, x_{v}\right\}, \hat{y}_{v} \in$ $\left\{\bar{y}_{v}, y_{v}\right\}$,

$$
\bar{Y}_{v}=\left[\bar{x}_{v} \bar{y}_{v}\right]_{X_{v}} \subset L_{v}
$$

By the definition, the points $\hat{x}_{v}, \hat{y}_{v}$ satisfy

$$
x_{v} \leq \hat{x}_{v} \leq \hat{y}_{v} \leq y_{v}
$$

in the oriented segment $\left[x_{v} y_{v}\right]_{X_{v}}$. (Compare Lemma 3.17(a3).)
This concludes the construction of the segments $L_{w}^{i}$. We just note that since $Q_{w} \subset X_{w}$ is $4 \delta_{0}$-quasiconvex and $x_{w}^{i} \in Q_{w}$ for all $i$, we get:

$$
Y_{w} \subset N_{5 \delta_{0}}^{f i b}\left(Q_{w}\right)
$$

These are the inductive assumptions we made earlier. We set

$$
\mathcal{L}^{i}:=\bigcap_{v \in V(T)} L_{v}^{i}, i=1,2,3 .
$$

We define a subtree of spaces $\mathfrak{Y} \subset \mathfrak{X}$ using the tripods $Y_{v}, Y_{e}$ as, respectively, vertex and edge-sets. The incidence maps $Y_{e} \rightarrow Y_{v}$ will be compositions of restrictions of incidence maps of $\mathfrak{X}$ with nearest-point projections $X_{v} \rightarrow Y_{v}$.

We, are done with the induction but it remains to verify that each $\mathcal{L}^{i}$ satisfies the properties required by Lemma 3.17: This lemma is used to promote the unions of geodesics segments in vertex spaces of $X$ to the union of vertex-spaces of a ladder. We also have to show that $\mathfrak{Y}$ ) is a ( $\kappa_{1}, D_{1}, E_{1}$ )-semicontinuous family in $\mathfrak{X}$, as required by the definition of a tripod of ladders, for suitable constants $\kappa_{1}, E_{1}$.

As we observed in the discussion of subcases, points $x_{w}^{i}$ satisfy

$$
\begin{equation*}
d_{X_{v w}}\left(\hat{x}_{v}^{i}, x_{w}^{i}\right) \leq k \tag{5.6}
\end{equation*}
$$

where $\hat{x}_{v}^{i} \in\left\{x_{v}^{i}, \bar{x}_{v}^{i}\right\}$.
We next turn our attention to the center $z_{w}$ of $Y_{w}$. Except for the generic subcase (d) above, the tripod $Y_{w}$ is degenerate and $z_{w}$ is one of its extremities, i.e. equals to one of the points $\tilde{x}_{w}^{j}$. Hence, apart from the generic case, as we observed while discussing nongeneric cases,

$$
\begin{equation*}
d_{X_{v w}}\left(z_{w}, \bar{x}_{v}^{j}\right) \leq k \tag{5.7}
\end{equation*}
$$

Note that the point $z_{w}$ is within uniformly bounded (in terms of $k$ ) distance from $z_{v}$ in subcase (2c) but might be quite far from $z_{v}$ in the subcase (b). The next lemma allows us to control the position of $z_{w}$ in the generic subcase (d).

Lemma 5.8. Suppose that we are in the generic subcase (d). Then

$$
d_{X_{v w}}\left(z_{v}, z_{w}\right) \leq C_{5.8}(k)
$$

Proof. We define the geodesic triangles (in $X_{v}, X_{w}$ ) $\hat{\Delta}_{v}:=\Delta \hat{x}_{v}^{1} \hat{x}_{v}^{2} \hat{x}_{v}^{3} . \Delta_{w}:=\Delta x_{w}^{1} x_{w}^{2} x_{w}^{3}$ and corresponding geodesic triangles in $X_{v w}$ :

$$
\hat{\Delta}_{v}^{*}:=\Delta_{X_{v w}} \hat{x}_{v}^{1} \hat{x}_{v}^{2} \hat{x}_{v}^{3}, \quad \Delta_{w}^{*}:=\Delta_{X_{v w}} x_{w}^{1} x_{w}^{2} x_{w}^{3}
$$

Then the points $z_{v}, z_{w}$ are, respectively, a $3 \delta_{0}$-center of $\hat{\Delta}_{v}$ and $\delta_{0}$-center of $\Delta_{w}$. Since the sides of $\hat{\Delta}_{v}$ are $L_{0}^{\prime}$-quasigeodesics in $X_{v w}$, stability of quasigeodesics implies that $z_{v}$ is within distance $3 \delta_{0}+D_{1.53}\left(\delta_{0}^{\prime}, L_{0}^{\prime}\right)$ from all three sides of $\hat{\Delta}_{v}^{*}$. Since the respective endpoints of the geodesic sides of the triangles $\hat{\Delta}_{v}^{*}, \Delta_{w}^{*}$ are within distance $k$ in $X$, it follows that $z_{v}$ is within distance $3 \delta_{0}+D_{1.53}\left(\delta_{0}^{\prime}, L_{0}^{\prime}\right)+\delta_{0}^{\prime}+k$ from all the sides of $\Delta_{w}^{*}$, i.e. $z_{v}$ is a $3 \delta_{0}+D_{1.53}\left(\delta_{0}^{\prime}, L_{0}^{\prime}\right)+\delta_{0}^{\prime}+k$-center of $\Delta_{w}^{*}$.

Similarly, the point $z_{w}$ is a $\delta_{0}+D_{1.53}\left(\delta_{0}^{\prime}, L_{0}^{\prime}\right)$-center of the triangle $\Delta_{w}^{*}$ in $X_{v w}$. Thus, by Lemma 1.76,

$$
d_{X_{v w}}\left(z_{w}, z_{v}\right) \leq D_{1.76}\left(\delta_{0}, 3 \delta_{0}+D_{1.53}\left(\delta_{0}^{\prime}, L_{0}^{\prime}\right)+\delta_{0}^{\prime}+k\right)
$$

Setting $C_{5.8}(k):=D_{1.76}\left(\delta_{0}, 3 \delta_{0}+D_{1.53}\left(\delta_{0}^{\prime}, L_{0}^{\prime}\right)+\delta_{0}^{\prime}+k\right)$ concludes the proof.
Corollary 5.9. For every edge $e=[v, w]$ (pointing away from $u$ ), we have

$$
\operatorname{Hd}_{X_{v w}}\left(\left[z_{v} \bar{x}_{v}^{i}\right]_{X_{v}}, L_{w}^{i}\right) \leq D_{5.9}(k)=D_{1.54}\left(\delta_{0}^{\prime}, L_{0}^{\prime}, C_{5.8}(k)\right),
$$

unless $L_{w}^{i}=\emptyset$. In any case,

$$
\operatorname{Hd}_{X_{v w}}\left(\bar{Y}_{v}, Y_{w}\right) \leq D_{5.9}(k)
$$

Proof. In the generic subcase (d) the first claim is an immediate application of Lemma 1.54 and Lemma 5.8. In other subcases, both tripods $\bar{Y}_{v}, Y_{w}$ are degenerate, equal to geodesic segments whose respective end-points are within distance $k$ in $X_{v w}$, e.g. $Y_{w}=L_{w}^{i}$. Therefore, we similarly conclude that

$$
\operatorname{Hd}_{X_{v w}}\left(\left[z_{v} \bar{x}_{v}^{i}\right]_{X_{v}}, L_{w}^{i}\right) \leq D_{1.54}\left(\delta_{0}^{\prime}, L_{0}^{\prime}, k\right)
$$

Observing that

$$
k \leq C_{5.8}(k),
$$

we obtain the first claim in other subcases as well. The second claim is an immediate corollary of the first one.

We are now ready to verify that $\mathfrak{Y}$ ) satisfies axioms of a $(K, D, E)$-semicontinuous family and that each $\mathfrak{L}^{i}$ is the vertex set of a ( $\kappa_{1}, D_{1}, E_{1}$ )-ladder. The constants $\kappa_{1}$ and $E_{1}$ will be computed in the end of the proof of the proposition.

In line with the proof of Lemma 3.17, for the edges $e=[v, w]$ (oriented away from $u$ ) we define tripods $Y_{e} \subset X_{e}$ as

$$
T_{z_{e}}\left(x_{e}^{1} x_{e}^{2} x_{e}^{3}\right)
$$

where $x_{e}^{i}$ is a nearest-point projection of $x_{w}^{i}$ to $X_{e}$ in $X_{v w}$, while $z_{e}$ is a $\delta_{0}$-center of the geodesic triangle $\Delta x_{e}^{1} x_{e}^{2} x_{e}^{3} \subset X_{e}$. Thus, by the construction, each $Y_{v}, Y_{e}$ is a $\delta_{0}$-quasiconvex subset of the respective vertex and edge-space of $\mathfrak{X}$.

According to Corollary 5.9, every point $x \in Y_{w}$ is within distance

$$
\begin{equation*}
\kappa_{1}:=D_{5.9}(k) \tag{5.8}
\end{equation*}
$$

from a point $y \in \bar{Y}_{v} \subset Y_{v}$. Thus, every point of $\boldsymbol{y}$ is connected to $X_{u}$ by a $k_{1}$-qi section. Similarly, we get the inequality $\operatorname{Hd}_{X_{v w}}\left(Y_{w}, Y_{e}\right) \leq \kappa_{1}$. Let's verify the inequality (3.2) (see Definition 3.1) for a suitable value of the parameter $E$, i.e. get a uniform bound on the Hausdorff distance between $Y_{w}$ and the projection of $Y_{v}$ to $X_{w}$. First of all, since

$$
d_{X_{v w}}\left(Y_{v}, X_{w}\right) \leq k=\max \left(4 \lambda_{0}^{\prime}+8 \delta_{0}^{\prime}+5 \delta_{0}, k\right)
$$

using Lemma 1.127 we obtain

$$
\begin{array}{r}
\operatorname{Hd}_{X_{v v}}\left(P_{Y_{v}}\left(X_{w}\right), P_{X_{w}}\left(Y_{v}\right)\right) \leq R_{1.127}\left(k, \lambda, \delta_{0}^{\prime}\right)= \\
2 \lambda_{0}^{\prime}+3 \delta_{0}^{\prime}+k
\end{array}
$$

Thus, we need to estimate the Hausdorff distance between $P_{Y_{v}}\left(X_{w}\right)$ and $Y_{w}$. According to (5.3),

$$
\operatorname{Hd}_{X_{v w}}\left(\bar{Y}_{v}, P_{Y_{v}}\left(X_{w}\right)\right) \leq \lambda
$$

Combining these inequalities with Corollary 5.9, we get:

$$
\begin{equation*}
\operatorname{Hd}_{X_{v w}}\left(P_{X_{w}}\left(Y_{v}\right), Y_{w}\right) \leq E_{1}:=D_{5.9}(k)+\lambda+\left(2 \lambda_{0}^{\prime}+3 \delta_{0}^{\prime}+k\right) \tag{5.9}
\end{equation*}
$$

For Axiom 4 of a semicontinuous family we observe that, by the construction, if $Y_{w}=\emptyset$ then $Y_{v}$ and $X_{w}$ are $D_{1}$-cobounded. We conclude:

Lemma 5.10. Y is a ( $\kappa_{1}, D_{1}, E_{1}$ )-semicontinuous family containing sections $\gamma^{1}, \gamma^{2}, \gamma^{3}$ and $\boldsymbol{Y} \subset N_{5 \delta_{0}}^{f i b}\left(\mathcal{F} l_{k}\left(X_{u}\right)\right)$.

Next, consider the families of intervals $\mathcal{L}^{i}, i=1,2,3\left(\mathcal{L}^{i}\right.$ is the union of geodesic intervals $L_{v}^{i}, v \in V(S)$ ). We will be verifying the conditions of Lemma 3.17 for each $\mathcal{L}^{i}$. The easiest thing to check is the first part of condition (a2) of the lemma, dealing with Property 4 of a semicontinuous family of spaces. Namely, by the definition of $L_{w}^{i}$, it is empty only when $L_{v}^{i}$ and $X_{w}$ are $D_{2}=D_{1}$-cobounded in $X_{v w}$, see Remarks 5.6 and 5.7.

Next, consider the condition (a3) of the lemma. Suppose $L_{w}^{i}$ is nonempty, equals the oriented segment $\left[x_{w}^{i} z_{w}\right]_{X_{w}}$. There are several cases to consider, for instance, suppose we are in the generic subcase (2d). Then there exists a point $\hat{x}_{v}^{i} \in\left[x_{v}^{i} z_{v}\right]_{X_{v}}=L_{v}^{i}$ within distance $k$ from $x_{w}^{i}$, while according to Lemma 5.8

$$
d_{X_{v w}}\left(z_{v}, z_{w}\right) \leq C_{5.8}(k)
$$

Of course, in this case, in the oriented interval $L_{v}^{i}$, we have

$$
x_{v}^{i} \leq \hat{x}_{v}^{i} \leq z_{v} \leq z_{v}
$$

In all nongeneric cases, there are points $\bar{x}_{v}^{i \pm 1}, \hat{x}_{v}^{i} \in L_{v}^{i}$ within distance $k$ from $z_{w}, x_{w}^{i}$ (subcase (2c)) or points $\hat{x}_{v}, \hat{y}_{v} \in L_{v}^{i}$ (or $L_{v}$ ) within distance $k$ from $x_{w}, y_{w}$ (subcase (2c) or case 3), and these points appear in the oriented interval $L_{v}^{i}$ (or $L_{v}$ ) in the correct order.

This verifies condition (a3) of Lemma 3.17 with the constant

$$
\begin{equation*}
k_{2}=\max \left(k, C_{5.8}(k)\right)=C_{5.8}(k) \tag{5.10}
\end{equation*}
$$

playing the role of $K$ in Lemma 3.17.
Lastly, we analyze the projection of $L_{v}^{i}$ to $X_{w}$. Similarly to the projection of $Y_{v}$ to $X_{w}$, we have:

$$
d_{X_{v w}}\left(L_{v}^{i}, X_{w}\right) \leq k
$$

and, thus,

$$
\begin{array}{r}
\operatorname{Hd}_{X_{v w}}\left(P_{L_{v}^{i}}\left(X_{w}\right), P_{X_{w}}\left(L_{v}^{i}\right)\right) \leq R_{1.127}(k, \lambda, \delta)=  \tag{5.11}\\
2 \lambda_{0}^{\prime}+3 \delta_{0}^{\prime}+k .
\end{array}
$$

In other words, the projection of $L_{v}^{i}$ to $X_{w}$ is uniformly Hausdorff-close to the projection of $X_{w}$ to $L_{v}^{i}$. Therefore, we analyze the latter using the arguments from the proof of Lemma 5.3. We have four projections:

$$
P_{X_{v w}, Y_{v}}, P_{X_{v w}, L_{v}^{i}}, P_{Y_{v}, L_{v}^{i}}, P_{Y_{v}, L_{v}^{i}}^{\prime}
$$

where the first three are nearest-point projections with respect to the metric of $X_{v w}$, while the last one is the intrinsic nearest-point projection with respect to the metric of $Y_{v}$. We have, of course,

$$
P_{Y_{v}, L_{v}^{i}}^{\prime} \circ P_{X_{v w}, Y_{v}}\left(X_{w}\right)=P_{X_{v w}, Y_{v}}\left(X_{w}\right) \cap\left[\bar{x}_{v}^{i} z_{v}\right]_{X_{v}} \subset P_{Y_{v}, L_{v}^{\prime}}^{\prime}\left(\bar{Y}_{v}\right)=\left[\bar{x}_{v}^{i} z_{v}\right]_{X_{v}} .
$$

According to Lemma 1.125,

$$
\begin{equation*}
\operatorname{Hd}_{X_{v w}}\left(P_{X_{v v}, Y_{v}}\left(X_{w}\right) \cap\left[\bar{x}_{v}^{i} z_{v}\right]_{X_{v}},\left[\bar{x}_{v}^{i} z_{v}\right]_{X_{v}}\right) \leq \lambda \tag{5.12}
\end{equation*}
$$

As in the proof of Lemma 5.3,

$$
d_{X_{v w}}\left(P_{X_{v w}, L_{v}^{i}}, P_{Y_{v}, L_{v}^{i}} \circ P_{X_{v w}, Y_{v}}\right) \leq C_{1.107}\left(\delta_{0}^{\prime}, \lambda_{0}^{\prime}\right)
$$

while for $x \in Y_{v}$,

$$
d_{X_{v w}}\left(P_{Y_{v}, L_{v}^{i}}(x), P_{Y_{v}, L_{v}^{i}}^{\prime}(x)\right) \leq 2\left(\lambda_{0}^{\prime}+2 \delta_{0}^{\prime}+D_{1.53}\left(\delta_{0}^{\prime}, L_{0}^{\prime}\right)\right) .
$$

Combining the two inequalities, we obtain that for each $q \in X_{w}$,

$$
\begin{array}{r}
d_{X_{v v}}\left(P_{Y_{v}, L_{v}^{i}}^{\prime} \circ P_{X_{v w}, Y_{v}}(q), P_{X_{v w}, L_{v}^{i}}(q)\right) \leq \\
C_{5.3}=C_{1.107}\left(\delta_{0}^{\prime}, \lambda_{0}^{\prime}\right)+2\left(\lambda_{0}^{\prime}+2 \delta_{0}^{\prime}+D_{1.53}\left(\delta_{0}^{\prime}, L_{0}^{\prime}\right)\right)
\end{array}
$$

Thus, taking into account (5.12),

$$
\operatorname{Hd}_{X_{v w}}\left(P_{X_{v w}, L_{v}^{\prime}}\left(X_{w}\right),\left[\bar{x}_{v}^{i} z_{v}\right]_{X_{v}}\right) \leq C_{5.3}+\lambda .
$$

Combined with the inequality (5.11), we get:

$$
\operatorname{Hd}_{X_{v w}}\left(P_{X_{w}}\left(L_{v}^{i}\right),\left[\bar{x}_{v}^{i} z_{v}\right]_{X_{v}}\right) \leq R_{1.127}\left(k, \lambda, \delta_{0}^{\prime}\right)+C_{5.3}+\lambda
$$

Recall that by Corollary 5.9

$$
\operatorname{Hd}_{X_{v w}}\left(\left[z_{v} \bar{x}_{v}^{i}\right]_{X_{v}}, L_{w}^{i}\right) \leq D_{5.9}(k)
$$

Thus,

$$
\begin{equation*}
\operatorname{Hd}_{X_{v w}}\left(P_{X_{w}}\left(L_{v}^{i}\right), L_{w}^{i}\right) \leq E_{2}:=D_{5.9}(k)+R_{1.127}\left(k, \lambda, \delta_{0}^{\prime}\right)+C_{5.3}+\lambda \tag{5.13}
\end{equation*}
$$

This concludes verification of the conditions of Lemma 3.17 and we obtain:
Lemma 5.11. For $k_{2}$ given by the equation (5.10), $\kappa_{2}=k_{2}^{\prime}=K_{3.17}^{\prime}\left(k_{2}\right), E_{2}$ as in (5.13), and $\lambda=C_{1.125}\left(\delta_{0}^{\prime}, \lambda_{0}^{\prime}, L_{0}^{\prime}\right)$, each $\mathcal{L}^{i}$ defined earlier is the vertex-set of a $\left(\kappa_{2}, D_{2}, E_{2}\right)$-ladder $\mathfrak{Q}^{i}$ in $\mathfrak{X}$. Each ladder $\mathfrak{Q}^{i}$ contains the section $\gamma^{i}$.

This concludes the proof of part (i) of the proposition. We now prove part (ii). The goal, of course, is to verify the conditions of Lemma 3.17 for the family of segments $L_{v}^{i j}, v \in V(S), j=i+1$. We define the monotonic map

$$
f_{i j}: L_{v}^{i} \cup L_{v}^{j} \rightarrow L_{v}^{i j}=\left[x_{v}^{i} x_{v}^{j}\right]_{X_{v}}
$$

using Corollary 1.80. According to Lemma 5.11, the map moves each point distance $\leq 4 \delta_{0}$. The points

$$
x_{v}^{\prime}:=f_{i j}\left(\hat{x}_{v}^{i}\right), y_{v}^{\prime}:=f_{i j}\left(\hat{x}_{v}^{j}\right) .
$$

satisfy

$$
x_{v}^{i} \leq x_{v}^{\prime} \leq y_{v}^{\prime} \leq x_{v}^{j}
$$

in the oriented interval $L_{v}^{i j}$. Since

$$
\max \left(d_{X_{v w}}\left(\hat{x}_{v}^{i}, x_{w}^{i}\right), d_{X_{v w}}\left(\hat{x}_{v}^{j}, x_{w}^{j}\right)\right) \leq k_{2}
$$

we obtain

$$
\begin{equation*}
\max \left(d_{X_{v w}}\left(x_{v}^{\prime}, x_{w}^{i}\right), d_{X_{v w}}\left(y_{v}^{\prime}, x_{w}^{j}\right)\right) \leq k_{3}:=k_{2}+4 \delta_{0} \tag{5.14}
\end{equation*}
$$

Next: Since $\left.L_{v}^{i j} \subset N_{2 \delta_{0}}^{f i b}\left(Y_{v}\right)\right)$,

$$
\operatorname{diam}\left(P_{X_{w}}\left(L_{v}^{i j}\right)\right) \leq L_{1}^{\prime} \cdot 3 \delta_{0}+\operatorname{diam}\left(P_{X_{w}}\left(Y_{v}\right)\right) \leq 3 \delta_{0}+D_{1}
$$

Since

$$
\begin{gather*}
\operatorname{Hd}_{X_{v}}\left(L_{v}^{i} \cup L_{v}^{j}, L_{v}^{i j}\right) \leq 2 \delta_{0},  \tag{5.15}\\
d_{X_{v w}}\left(P_{L_{v}^{i} \cup L_{v}^{j}}, P_{L_{v}^{i j}}\right) \leq 2 \delta_{0}+2\left(\lambda_{0}^{\prime}+2 \delta_{0}^{\prime}\right) .
\end{gather*}
$$

Therefore,

$$
\begin{gather*}
\operatorname{diam}\left(P_{L_{v}^{i j}}\left(X_{w}\right)\right) \leq \operatorname{diam}\left(P_{L_{v}^{i} \cup L_{v}^{j}}\left(X_{w}\right)\right)+2 \delta_{0}+2\left(\lambda_{0}^{\prime}+2 \delta_{0}^{\prime}\right) \leq  \tag{5.16}\\
\operatorname{diam}\left(P_{Y_{v}}\left(X_{w}\right)\right)+2 \delta_{0}+2\left(\lambda_{0}^{\prime}+2 \delta_{0}^{\prime}\right) \leq D_{1}+2 \delta_{0}+2\left(\lambda_{0}^{\prime}+2 \delta_{0}^{\prime}\right) . \tag{5.17}
\end{gather*}
$$

Therefore, for

$$
D_{3}:=D_{1}+\max \left(3 \delta_{0}, 2 \delta_{0}+2\left(\lambda_{0}^{\prime}+2 \delta_{0}^{\prime}\right)\right),
$$

for every boundary edge $e=[v, w]$ of $S$, the subsets $L_{v}^{i j}, X_{w} \subset X_{v w}$ are $D_{3}$-cobounded.
Lastly, we estimate the Hausdorff distance between the projection of $L_{v}^{i j}$ to $X_{w}$ and $L_{w}^{i j}$ for every edge $e=[v, w] \in S$. We again use the inequality (5.15) and the coarse Lispchitz property of the projection $P_{X_{w w}, X_{w}}$ :

$$
\operatorname{Hd}\left(P_{X_{w}}\left(L_{v}^{i} \cup L_{v}^{j}\right), P_{X_{w}}\left(L_{v}^{i j}\right)\right) \leq L_{1}^{\prime} \cdot 3 \delta_{0}
$$

Therefore, the inequality (5.13), implies that

$$
\operatorname{Hd}\left(P_{X_{w}}\left(L_{v}^{i j}\right), L_{w}^{i j}\right) \leq E_{3}:=L_{1}^{\prime} \cdot 5 \delta_{0}+E_{2} .
$$

It follows (in view of Lemma 3.17) that $\mathfrak{L}^{i j}$ is the union of vertex-sets of a ( $\kappa_{3}, D_{3}, E_{3}$ )ladder, $\kappa_{3}=k_{3}^{\prime}$. Taking

$$
K:=\max \left(\kappa_{1}, \kappa_{2}, \kappa_{3}\right), D:=\max \left(D_{1}, D_{3}\right), E:=\max \left(E_{1}, E_{2}, E_{3}\right),
$$

concludes the proof of the proposition.
Corollary 5.12. For $k, K, D, E$ as in the proposition, any two points $x, y \in \mathfrak{F} l_{k}\left(X_{u}\right)$ belong to a $(K, D, E)$-ladder $\mathfrak{L}$ centered at $u$ and contained in the fiberwise $4 \delta_{0}$-neighborhood of $\mathfrak{F} l_{k}\left(X_{u}\right)$. Furthermore, if we are given two $k$-leaves $\gamma_{x}, \gamma_{y}$ in $F l_{k}\left(X_{u}\right)$ connecting $x, y$ to $X_{u}$, the ladder $\mathfrak{Z}$ can be chosen to satisfy:

$$
\gamma_{x} \subset \operatorname{bot}(\mathfrak{L}), \gamma_{y} \subset \operatorname{top}(\mathfrak{L})
$$

### 5.2. Projection of ladders

In this section we discuss an important projection procedure which converts a pair of ladders $\mathfrak{L}^{i}=\left(\pi: L^{i} \rightarrow S_{i}\right), i=1,2$, with the common center $u$ into a pair of subladders $\overline{\mathfrak{L}}^{i} \subset$ $\mathfrak{Q}^{i}, i=1,2$ (with the same center $u$, but possibly a different set of qi sections $\bar{\Sigma}_{\bullet}$ ), within uniformly bounded (fiberwise) Hausdorff distance from each other. This construction will be used in Section 5.4 to show the coarse independence of a combing path $c(x, y)$ in a ladder $L_{x, y}$ containing the given points $x, y$ on the choice of a ladder $L_{x, y}$.

The intersection $\pi\left(\mathfrak{L}^{1}\right) \cap \pi\left(\mathfrak{L}^{2}\right)=S_{1} \cap S_{2}$ is a subtree $S \subset T$. This subtree will contain (but, in general will be different from) the tree $\bar{S}$ which is the common base of the ladders $\pi: \overline{\mathfrak{Z}} i \rightarrow \bar{S}$. For each $v \in V(S)$ we let

$$
\bar{L}_{v}^{1}:=\bar{P}_{X_{v}, L_{v}^{1}}\left(L_{v}^{2}\right) \subset L_{v}^{1}, \bar{L}_{v}^{2}:=\bar{P}_{X_{v}, L_{v}^{2}}\left(L_{v}^{1}\right) \subset L_{v}^{2}
$$

see Definition 1.121 for the definition of the modified fiberwise projection $\bar{P}$. In the definition of ladders $\overline{\mathfrak{L}}^{i}$ below, the segment $\bar{L}_{v}^{i}$ will equal the fiber $\bar{L}_{v}^{i}$ of $\overline{\mathfrak{L}}^{i}$, unless $v \notin V(\bar{S})$.

By Lemma 1.139 and Corollary 1.140 we have the dichotomy:
i. Either the pair of geodesic segments $L_{v}^{1}, L_{v}^{2} \subset X_{v}$ is $7 \delta_{0}$-separated (i.e. $d_{X_{v}}\left(L_{v}^{1}, L_{v}^{2}\right)>$ $7 \delta_{0}$ ), in which case this pair is $D_{1.139}(\delta, \delta)=9 \delta_{0}$-cobounded.
ii. $\operatorname{Or} d_{X_{v}}\left(L_{v}^{1}, L_{v}^{2}\right) \leq 7 \delta_{0}$ and

$$
\operatorname{Hd}_{X_{v}}\left(P_{L_{v}^{1}}\left(L_{v}^{2}\right), P_{L_{v}^{2}}\left(L_{v}^{1}\right)\right) \leq 12 \delta_{0} .
$$

According to Remark 1.124, in this case

$$
\operatorname{Hd}_{X_{v}}\left(P_{L_{v}^{1}}\left(L_{v}^{2}\right), \bar{L}_{v}^{1}\right) \leq 4 \delta_{0}
$$

and

$$
\operatorname{Hd}_{X_{v}}\left(P_{L_{v}^{2}}\left(L_{v}^{1}\right), \bar{L}_{v}^{2}\right) \leq 4 \delta_{0}
$$

Combining the inequalities, we get that in the second case,

$$
\begin{equation*}
\operatorname{Hd}_{X_{v}}\left(\bar{L}_{v}^{1}, \bar{L}_{v}^{2}\right) \leq 20 \delta_{0} \tag{5.18}
\end{equation*}
$$

Accordingly, for each vertex $v \in S$ such that the pair of geodesic segments $L_{v}^{1}, L_{v}^{2} \subset X_{v}$ is $7 \delta_{0}$-separated, we remove from $V(S)$ all the vertices (and edges) $w \neq v$ such that $v$ is between $u$ and $w$; we let $\bar{S}$ denote the subtree of $S$ spanned by the remaining set of vertices of $S$. Note that if $v=u, \bar{S}=\{u\}$.

We define

$$
\overline{\mathcal{L}}^{i}:=\bigcup_{v \in V(\bar{S})} \bar{L}_{v}^{i}
$$

Thus, apart from the boundary vertices $v$ of $\bar{S}$, the intervals $\bar{L}_{v}^{1}, \bar{L}_{v}^{2}$ are fiberwise Hausdorff $20 \delta_{0}$-close, while for some boundary vertices $v$ of $\bar{S}$, both $\bar{L}_{v}^{1}, \bar{L}_{v}^{2}$ have length $\leq 9 \delta_{0}$. We will prove (Claim 5.15) that even for the boundary vertices of $\bar{S}$, the Hausdorff distance between the intervals $\bar{L}_{v}^{1}, \bar{L}_{v}^{2}$ is also uniformly bounded.

Remark 5.13. By the construction, both $\overline{\mathcal{L}}^{i}$ contain the intersection $\mathcal{L}^{1} \cap \mathcal{L}^{2}$.
Thus, we obtain subsets $\overline{\mathcal{L}}^{i} \subset \mathcal{X}$ which are unions of geodesic segments in vertexspaces $X_{v}, v \in V(\bar{S})$. Our next goal it to prove that these subsets are unions of vertex-spaces of ladders in $\mathfrak{X}$.

Recall that $L_{1}^{\prime}$ is a coarse Lipschitz constant for the composition of the inclusion map $X_{v} \rightarrow X_{v w}$ with the nearest-point projection $P_{X_{w w}, X_{w}}: X_{v w} \rightarrow X_{w}$, cf. Notation 2.6.4. Set

$$
\begin{aligned}
\epsilon=\epsilon_{5.14}(E)= & E+\left(2 E+21 \delta_{0} L_{1}^{\prime}\right)+L_{1.99}\left(\delta_{0}, \delta_{0}\right)\left(2 E+21 \delta_{0} L_{1}^{\prime}+1\right) \\
k & :=2\left(2 K+\epsilon+20 \delta_{0}\right)+K+\epsilon+20 \delta_{0}
\end{aligned}
$$

$$
\begin{gathered}
\tilde{K}=\tilde{K}_{5.14}(K, E)=K_{3.17}^{\prime}(k), \\
\tilde{E}:=\tilde{E}_{5.14}(K, E)=2 k \\
\tilde{D}:=\tilde{D}_{5.14}(D)=\max \left(10 \delta_{0} \cdot L_{1}^{\prime}, D, C_{1.140}\left(\lambda_{0}^{\prime}, \delta_{0}^{\prime}, 21 \delta_{0} L_{1}^{\prime}\right)\right)
\end{gathered}
$$

Proposition 5.14 (Projections of pairs of ladders). If $\mathfrak{L}^{1}, \mathfrak{L}^{2}$ are ( $K, D, E$ )-ladders centered at $u$, then there exist $(\tilde{K}, \tilde{D}, \tilde{E})$-ladders $\overline{\mathfrak{D}}^{i}=\left(\pi: \bar{L}^{i} \rightarrow \bar{S}\right), i=1,2$, centered at $u$, where $\tilde{K}=\tilde{K}_{5.14}(K, E), \tilde{D}=\tilde{D}_{5.14}(D), \tilde{E}=\tilde{E}_{5.14}(K, E)$, such that $\overline{\mathcal{L}}^{i}=\bar{L}^{i} \cap \mathcal{X}$ is the union of vertex-spaces of $\overline{\mathfrak{Q}}^{i}$.

Proof. As with tripods of ladders, we will prove the proposition by verifying the conditions of Lemma 3.17. Below, $e=[v, w]$ is an edge of $T$ oriented away from $u$, with $v \in V(\bar{S})$.

1. We first check part 1 of the condition (a2) in Lemma 3.17, i.e. that for every boundary edge $e$ of $\bar{S}, e=[v, w] \notin E(\bar{S}), v \in V(\bar{S})$, both pairs of subsets $\bar{L}_{v}^{i}, X_{w} \subset X_{v w}$ are $\tilde{D}$-cobounded, $i=1,2$.
(i) It can happen that $e=[v, w] \notin E(\bar{S})$ because the pair $L_{v}^{1}, L_{v}^{2} \subset X_{v}$ was $7 \delta_{0}$-separated, i.e. both $\bar{L}_{v}^{1}, \bar{L}_{v}^{2}$ have length $\leq 9 \delta_{0}$. Since the projection $P_{X_{v v}, X_{w}}: X_{v w} \rightarrow X_{w}$ is $L_{1}^{\prime}$-coarse Lipschitz, diameters of the projections $P_{X_{v w}, X_{w}}\left(\bar{L}_{v}^{i}\right) \subset X_{w}$ are at most $10 \delta_{0} \cdot L_{1}^{\prime} \leq \tilde{D}$. (Recall that $\delta_{0} \geq 1$.)
(ii) If the pair $L_{v}^{1}, L_{v}^{2} \subset X_{v}$ was not $7 \delta_{0}$-separated then the Hausdorff distance in $X_{v}$ between $\bar{L}_{v}^{1}, \bar{L}_{v}^{2}$ is $\leq 20 \delta_{0}$. After swapping the labels of 1 and 2 we may assume that there is an edge $e=[v, w] \notin E\left(S_{1}\right)$. Then, because $\mathfrak{L}^{1}$ was a $(K, D, E)$-ladder, the pair $L_{v}^{1}, X_{w}$ is $D$-cobounded in $X_{v w}$. The same, of course applies to the pair $\bar{L}_{v}^{1}, X_{w}$, since $\bar{L}_{v}^{1} \subset L_{v}^{1}$. We need to get a coboundedness estimate for the pair $\bar{L}_{v}^{2}, X_{w}$. Since

$$
\begin{equation*}
\operatorname{Hd}_{X_{v}}\left(\overline{\mathcal{L}}_{v}^{1}, \overline{\mathcal{L}}_{v}^{2}\right) \leq 20 \delta_{0} \tag{5.19}
\end{equation*}
$$

and the projection $P_{X_{v w}, X_{w}}: X_{v} \rightarrow X_{w}$ is coarse $L_{1}^{\prime}$-Lipschitz, the diameter the projection of $\bar{L}_{v}^{2}$ to $X_{w}$ is at most

$$
L_{1}^{\prime}\left(20 \delta_{0}+1\right) \leq 21 \delta_{0} L_{1}^{\prime} \leq \tilde{D}
$$

The estimate

$$
\operatorname{diam}_{X_{v w}}\left(P_{X_{w w}, \bar{L}_{v}^{2}}\left(X_{w}\right)\right) \leq C_{1.140}\left(\lambda_{0}^{\prime}, \delta_{0}^{\prime}, 21 \delta_{0} L_{1}^{\prime}\right)
$$

follows from Corollary 1.140 .
This verifies part 1 of the condition (a2) in Lemma 3.17.
2. We assume now that $e=[v, w]$ is an edge of $\bar{S}$, in particular, $\bar{L}_{v}^{1}, \bar{L}_{v}^{2}$ are $20 \delta_{0}$ Hausdorff close in $X_{v}$. Since $\mathfrak{L}^{1}, \mathfrak{L}^{2}$ satisfy the ( $K, D, E$ )-ladder axioms, for $P=P_{X_{v v}, X_{w}}$, $P\left(L_{v}^{i}\right)$ and $L_{w}^{i}$ are $E$-Hausdorff close in $X_{v w}, i=1,2$. Our goal is to estimate the Hausdorff distance between $L_{w}^{i}$ and the projection of $L_{v}^{i}$ to $X_{w}(i=1,2)$. In this part of the proof we will get only half of the estimate, we will get the other half in Part 4 of the proof.

Pick $x \in \bar{L}_{v}^{1}$. Then there exists $y \in \bar{L}_{v}^{2}$ such that $d_{X_{v}}(x, y) \leq 20 \delta_{0}$; we also have

$$
d_{X_{w}}\left(P(x), L_{w}^{1}\right) \leq E, \quad d_{X_{w}}\left(P(y), L_{w}^{2}\right) \leq E .
$$

Thus, there exist $x^{\prime} \in L_{w}^{1}$ and $y^{\prime} \in L_{w}^{2}$ such that

$$
\begin{equation*}
d_{X_{w}}\left(P(x), x^{\prime}\right) \leq E, \quad d_{X_{w}} d\left(P(y), y^{\prime}\right) \leq E, \tag{5.20}
\end{equation*}
$$

which in turn implies the inequality

$$
\begin{equation*}
d_{X_{w}}\left(x^{\prime}, y^{\prime}\right) \leq 2 E+21 \delta_{0} L_{1}^{\prime} \tag{5.21}
\end{equation*}
$$

We next estimate the distance $d_{X_{w}}\left(y^{\prime}, \bar{L}_{w}^{2}\right)$. Since the projection $P^{\prime}: X_{w} \rightarrow L_{w}^{2}$ is $L_{1.99}\left(\delta_{0}, \delta_{0}\right)$-coarse Lipschitz, we have

$$
d_{X_{w}}\left(P^{\prime}\left(x^{\prime}\right), y^{\prime}\right) \leq L_{1.99}\left(\delta_{0}, \delta_{0}\right)\left(d_{X_{w}}\left(x^{\prime}, y^{\prime}\right)+1\right) \leq L_{1.99}\left(\delta_{0}, \delta_{0}\right)\left(2 E+21 \delta_{0} L_{1}^{\prime}+1\right) .
$$

Since $x^{\prime} \in L_{w}^{1}, P^{\prime}\left(x^{\prime}\right) \in \bar{L}_{w}^{2}$, and we obtain:

$$
\begin{equation*}
d_{X_{w}}\left(y^{\prime}, \bar{L}_{w}^{2}\right) \leq L_{1.99}\left(\delta_{0}, \delta_{0}\right)\left(2 E+21 \delta_{0} L_{1}^{\prime}+1\right) . \tag{5.22}
\end{equation*}
$$

Switching the roles of $x$ and $y$ we similarly obtain:

$$
\begin{equation*}
d_{X_{w}}\left(x^{\prime}, \bar{L}_{w}^{1}\right) \leq L_{1.99}\left(\delta_{0}, \delta_{0}\right)\left(2 E+21 \delta_{0} L_{1}^{\prime}+1\right) . \tag{5.23}
\end{equation*}
$$

Combining the equations (5.20) and (5.23) we obtain

$$
d_{X_{w}}\left(P(x), \bar{L}_{w}^{1}\right) \leq E+L_{1.99}\left(\delta_{0}, \delta_{0}\right)\left(2 E+21 \delta_{0} L_{1}^{\prime}+1\right)
$$

and, similarly, combining (5.20) and (5.22) we obtain

$$
d_{X_{w}}\left(P(y), \bar{L}_{w}^{2}\right) \leq E+L_{1.99}\left(\delta_{0}, \delta_{0}\right)\left(2 E+21 \delta_{0} L_{1}^{\prime}+1\right)
$$

At the same time, combing the equations (5.20), (5.21) and (5.22) we get:

$$
d_{X_{w}}\left(P(x), \bar{L}_{w}^{2}\right) \leq E+\left(2 E+21 \delta_{0} L_{1}^{\prime}\right)+L_{1.99}\left(\delta_{0}, \delta_{0}\right)\left(2 E+21 \delta_{0} L_{1}^{\prime}+1\right) \leq \tilde{E} .
$$

Similarly,

$$
d_{X_{w}}\left(P(y), \bar{L}_{w}^{1}\right) \leq \epsilon=E+\left(2 E+21 \delta_{0} L_{1}^{\prime}\right)+L_{1.99}\left(\delta_{0}, \delta_{0}\right)\left(2 E+21 \delta_{0} L_{1}^{\prime}+1\right)
$$

Thus, we proved:

$$
P\left(\bar{L}_{v}^{1}\right) \cup P\left(\bar{L}_{v}^{2}\right) \subset N_{\epsilon}^{e}\left(\bar{L}_{w}^{1}\right) \cap N_{\epsilon}^{e}\left(\bar{L}_{w}^{2}\right),
$$

which gives us half of the estimate on $\operatorname{Hd}_{X_{v v}}\left(P\left(\bar{L}_{v}^{i}\right), \bar{L}_{w}^{i}\right)$, but also gives an upper bound on the minimal distance between $\bar{L}_{w}^{1}$ and $\bar{L}_{w}^{2}$, something which was not a priori clear from the construction. We will derive the other half of the estimate on $\operatorname{Hd}_{X_{v w}}\left(P\left(\bar{L}_{v}^{i}\right), \bar{L}_{w}^{i}\right)$ in Part 4 of the proof. Before proceeding with Part 3 of the proof we establish:

Claim 5.15. For every vertex $w \in V(\bar{S})$

$$
\operatorname{Hd}_{X_{v w}}\left(\bar{L}_{w}^{1}, \bar{L}_{w}^{2}\right) \leq C_{5.15}(E)=\epsilon+20 \delta_{0} .
$$

Proof. There are two cases to consider according to the definition of the projections $\overline{\mathcal{L}}^{i}:$
(i) Suppose that the pair of geodesic segments $L_{w}^{1}, L_{w}^{2}$ is $7 \delta_{0}$-separated, hence, each segment $\bar{L}_{w}^{i}, i=1,2$ has length $\leq 9 \delta_{0}$. As we observed in the end of the Part 2 of the proof, there exists $z \in X_{w}$ which lies in the intersection

$$
N_{\epsilon}^{e}\left(\bar{L}_{w}^{1}\right) \cap N_{\epsilon}^{e}\left(\bar{L}_{w}^{2}\right) .
$$

Therefore,

$$
\operatorname{Hd}_{X_{v w}}\left(\bar{L}_{w}^{1}, \bar{L}_{w}^{2}\right) \leq \epsilon+9 \delta_{0} .
$$

(ii) Suppose that the pair of geodesic segments $L_{w}^{1}, L_{w}^{2}$ is not $9 \delta_{0}$-cobounded. According to (5.18),

$$
\operatorname{Hd}_{X_{v}}\left(\overline{\mathcal{L}}_{v}^{1}, \overline{\mathcal{L}}_{v}^{2}\right) \leq 20 \delta_{0}
$$

We now return to the proof of the proposition.
3. We next verify the condition (a3) in Lemma 3.17.

Since $\mathfrak{L}^{i}, i=1,2$ were $K$-ladders, each $x_{i} \in \bar{L}_{w}^{i}$ is within distance $K$ (measured in $X_{v w}$ ) from some point in $L_{v}^{i}$. Thus, setting $y_{i}:=P_{X_{v v}, L_{v}^{i}}\left(x_{i}\right)$,

$$
d_{X_{v w}}\left(x_{i}, y_{i}\right) \leq 2 K, i=1,2
$$

According to Claim 5.15, given $x_{1} \in \bar{L}_{w}^{1}$ we can find $x_{2} \in \bar{L}_{w}^{2}$ such that

$$
d_{X_{v w}}\left(x_{1}, x_{2}\right) \leq \epsilon+20 \delta_{0}
$$

Thus,

$$
d_{X_{v w}}\left(y_{1}, y_{2}\right) \leq 2 K+\epsilon+20 \delta_{0}
$$

Let $\bar{y}_{i}$ denote a nearest-point projection of $y_{i}$ to $L_{v}^{3-i}, i=1,2$. Then the above inequality implies that

$$
d_{X_{v w}}\left(\bar{y}_{i}, y_{i}\right) \leq 2\left(2 K+\epsilon+20 \delta_{0}\right) .
$$

However, by the construction, $\bar{y}_{i}$ belongs to $\bar{L}_{v}^{3-i}$. Hence, by the above estimates:

$$
d_{X_{v w}}\left(x_{1}, \bar{L}_{v}^{1}\right) \leq d_{X_{v w}}\left(x_{1}, \bar{y}_{2}\right) \leq k:=2\left(2 K+\epsilon+20 \delta_{0}\right)+K+\epsilon+20 \delta_{0}
$$

Similarly, for each $x_{2} \in \bar{L}_{w}^{2}$ we have

$$
d_{X_{v w}}\left(x_{2}, \bar{L}_{v}^{2}\right) \leq k=2\left(2 K+\epsilon+20 \delta_{0}\right)+K+\epsilon+20 \delta_{0}
$$

This verifies the condition (a3) in Lemma 3.17.
4. By Part 3, each $x \in \bar{L}_{w}^{i}$ is within distance $k$ from some $y \in \bar{L}_{v}^{i}, i=1,2$. Therefore,

$$
d_{X_{v w}}\left(x, P_{X_{v w}, X_{w}}(y)\right) \leq 2 k
$$

In other words,

$$
\bar{L}_{w}^{i} \subset N_{2 k}^{e}\left(P_{X_{v w}, X_{w}}\left(\bar{L}_{v}^{i}\right)\right) .
$$

Combining this with the estimate in the end of Part 2, we obtain:

$$
\operatorname{Hd}_{X_{v w}}\left(P\left(\bar{L}_{v}^{i}\right), \bar{L}_{w}^{i}\right) \leq \max (2 k, \epsilon)=2 k=\tilde{E} .
$$

Since we defined $\tilde{E}$ to be $2 k$, we are done with the proof of the proposition.

### 5.3. Hyperbolicity of tripods families

Proposition 5.16 (Tripod families are hyperbolic). Suppose that $\mathfrak{X}$ is a tree of hyperbolic spaces satisfying the uniform $\kappa_{4.5}(K)$-flaring condition. Then for each ( $K, D, E$ )tripod family $\mathfrak{Y}=(\pi: Y \rightarrow S)$ in $\mathfrak{X}$, the total space $Y$ is $\delta_{5.16}(K)$-hyperbolic.

Proof. The total space $Y$ of $\mathfrak{Y}$ ) is the union of total spaces $L^{i}$ of the ladders $\mathfrak{Q}^{i}, i=$ $1,2,3$. The pairwise intersections of these ladders equal their triple intersection, namely, the $K$-qi section $\Xi$, which is, intrinsically, a tree. Thus, $Y$ has a structure of a tree of spaces with the vertex-spaces $L^{i}, i=1,2,3$, and $\Xi$. According to Theorem 4.13 each ladder $L^{i}$ is $\delta_{4.13}(K)$-hyperbolic (this is where we need the $\kappa_{4.5}(K)$-flaring condition), the space $Y$ is $\delta_{5.16}(K)$-hyperbolic according to Corollary 2.63 .

### 5.4. Hyperbolicity of flow-spaces

In the following theorem, we fix $k \geq k_{5.2}, K=K_{5.2}(k)$.
Theorem 5.17. Suppose that $k, K$ are as above, $\mathfrak{X}$ is a tree of hyperbolic spaces satisfying the uniform $\kappa_{4.5}(K)$-flaring condition. Then there is a function $\delta=\delta_{5.17}(\mathrm{k})$ such that for each $u \in v(T)$, the flow space $F l_{k}\left(X_{u}\right)$ is $\delta$-hyperbolic.

Proof. According to Corollary 5.12, whenever $k \geq k_{5.2}, K=K_{5.2}(k), D=D_{5.2}$, $E=E_{5.2}$, for any two points $x, y \in \mathcal{F} l_{k}\left(X_{u}\right)$ there exists a $(K, D, E)$-ladder $\mathfrak{Z}=\mathfrak{L}_{x, y}$ centered at $u$ and containing $x, y$, such that $\mathcal{L}$ is contained in the fiberwise $5 \delta_{0}$-neighborhood of $\mathcal{F} l_{k}\left(X_{u}\right)$.

Recall that the total space $L_{x, y}$ of the ladder $\mathfrak{Z}$ is $L_{3.4}\left(K, D, E, \delta_{0}\right)$-qi embedded in $X$. Define $c(x, y)$ to be a projection to $F l_{k}\left(X_{u}\right)$ of a geodesic in $L_{x, y}$ connecting $x$ to $y$. We note
that the definition of $c(x, y)$ depends on the choice of $\mathfrak{L}_{x y}$ which is far from canonical. Our first task is to prove that different choices lead to uniformly Hausdorff-close paths.

Proposition 5.18. Let $\mathfrak{Q}^{1}=\mathfrak{L}_{x, y}^{1}, \mathfrak{Q}^{2}=\mathfrak{Q}_{x, y}^{2}$ be ( $K, D, E$ )-ladders containing $x, y$. Then $L_{x, y}^{1} \cup L_{x, y}^{2}$ is contained in a $\delta_{5.18}(K, D, E)$-hyperbolic subspace $Z$ in $X$.

Proof. We let $\overline{\mathfrak{L}}^{i} \subset \mathfrak{L}^{i}$ denote the ( $\left.\tilde{K}, \tilde{D}, \tilde{E}\right)$-subladders obtained by the projection construction described in Section 5.2; see also Proposition 5.14. Note that $\tilde{K} \geq K, \tilde{E} \geq$ $E, \tilde{D} \geq D$. Also, note that the subladders $\overline{\mathfrak{L}}^{i}$ are nonempty since they both contain $x$ and $y$.

The subladders $\bar{L}^{i}$ have equal projection to $T$, which is a subtree $\bar{S} \subset S_{1} \cap S_{2}$. As usual, we extend these ladders over the rest of the tree $S_{1} \cup S_{2}$ by empty fibers. According to Claim 5.15, the ladders $\overline{\mathfrak{Z}}^{1}, \overline{\mathfrak{Z}}^{2}$ are fiberwise $C_{5.15}(E)$-Hausdorff close. Therefore, for each $v \in V(\bar{S})$ the union $\bar{L}_{v}^{1} \cup \bar{L}_{v}^{2}$ is $C_{5.15}(E)+\delta_{0}$-quasiconvex in $X_{v}$. For each vertex $v \in V(S)$ we set

$$
\begin{aligned}
& Z_{v}^{0}:=\operatorname{Hull}_{\delta_{0}}\left(\bar{L}_{v}^{1} \cup \bar{L}_{v}^{2}\right), \\
& Z_{v}^{i}:=L_{v}^{i} \cup Z_{v}^{0}, i=1,2,
\end{aligned}
$$

and $Z_{v}:=Z_{v}^{1} \cup Z_{v}^{2}$. Thus, $Z_{v}^{j}(j=0,1,2)$ and $Z_{v}$ are rectifiably connected $4 \delta_{0}$-quasiconvex subsets of $X_{v}$ (see Lemma 1.96). By (1.3),

$$
\operatorname{Hd}_{X_{v}}\left(Z_{v}^{0}, \bar{L}_{v}^{1} \cup \bar{L}_{v}^{2}\right) \leq C_{5.15}(E)+2 \delta_{0}
$$

and, hence,

$$
\begin{equation*}
\operatorname{Hd}_{X_{v}}\left(Z_{v}^{0}, \bar{L}_{v}^{i}\right) \leq 2 C_{5.15}(E)+2 \delta_{0}, i=1,2 . \tag{5.24}
\end{equation*}
$$

Accordingly,

$$
\operatorname{Hd}_{X_{v}}\left(Z_{v}^{i}, L_{v}^{i}\right) \leq 2 C_{5.15}(E)+2 \delta_{0}, i=1,2
$$

We repeat the same construction (and estimates) for all edges $e \in E(\bar{S})$. We, thus, obtain four subtrees of spaces $\mathcal{3}^{j}(j=0,1,2)$ and $\mathcal{Z}$ in $\mathfrak{X}$ whose vertex-spaces are, respectively $Z_{v}^{j}(j=0,1,2)$ and $Z_{v}, v \in V(S)$. The total space $Z$ of 3 contains both ladders $L^{1}, L^{2}$. We equip $Z^{j}$,s and $Z$ with natural path-metrics $d_{Z^{j}}, d_{Z}$; the goal is to show that $Z$ is uniformly hyperbolic. The space $Z$ is the union of subsets $Z^{1}, Z^{2}$ whose intersection is $Z^{0}$. According to Corollary 3.4, the ladders $L^{i}, \bar{L}^{i}, i=1,2$ are $L_{3.4}\left(\tilde{K}, \tilde{D}, \tilde{E}, \delta_{0}\right)$-qi embedded in $X$. In view of (5.24), the inclusion $Z^{0} \rightarrow Z$ is an $\left(L_{3.4}\left(\tilde{K}, \tilde{D}, \tilde{E}, \delta_{0}\right), 2 C_{5.15}(E)+2 \delta_{0}\right)$-qi embedding.

Thus, $Z=Z^{1} \cup Z^{2}$ satisfies the assumptions of Theorem 2.59 and, therefore, is $\delta$ hyperbolic for some $\delta$ which depends only on $K, D, E$.

Corollary 5.19. Let $L_{x, y}^{i}, i=1,2$ be two ( $K, D, E$ )-ladders containing $x, y$ and $c^{i}(x, y)$ be projections to $F l_{k}\left(X_{u}\right)$ of geodesics $[x y]^{i} \subset L_{x, y}^{i}$. Then

$$
\operatorname{Hd}_{X}\left(c^{1}(x, y), c^{2}(x, y)\right) \leq C_{5.19}(K, D, E)
$$

Proof. The paths $c^{i}(x, y)$ are uniformly close to the geodesic segments $[x y]^{i} \subset L_{x, y}^{i}, i=$ 1,2 ; hence, it suffices to bound the Hausdorff distance between these segments. Since both $[x y]^{i}$ are contained in a $\delta_{5.19}(K, D, E)$-hyperbolic space $\left(Z, d_{Z}\right)$ and are $L_{3.4}\left(K, D, E, \delta_{0}\right)$ quasigeodesics in $Z$ with common end-points, by Lemma 1.54, we get:

$$
\begin{align*}
& \operatorname{Hd}_{X}\left([x y]^{1},[x y]^{2}\right) \leq \operatorname{Hd}_{Z}\left([x y]^{1},[x y]^{2}\right) \leq  \tag{5.25}\\
& \quad D_{1.54}\left(\delta_{5.19}(K, D, E), L_{3.4}(K, D, E, 0)\right) . \tag{5.26}
\end{align*}
$$

Corollary follows.
We now check that the family of paths $c$ satisfies the conditions of the Corollary 1.64, characterizing hyperbolic spaces; this will conclude the proof of the theorem.

Condition a1: This follows from the fact that $c(x, y)$ is within uniformly bounded distance from a geodesic in $L_{x, y}$ and that $L_{x, y}$ is $L_{3.4}\left(K^{\prime}, D, E, \delta_{0}\right)$-qi embedded in $X$.

Condition a2: Consider points $x, y, z \in \mathcal{F} l_{k}\left(X_{u}\right)$. According to Proposition 5.2, there exists a $(K, D, E)$-tripod family $\mathfrak{Y})=(\pi: Y \rightarrow S)$ contained the fiberwise $5 \delta_{0}$-neighborhood of $\mathcal{F} l_{k}\left(X_{u}\right)$ and containing the points $x, y, z$. Moreover, according to Part (ii) of Proposition 5.2, there are ( $K, D, E$ )-ladders $\mathfrak{L}_{x, y}, \mathfrak{L}_{y, z}, \mathfrak{L}_{z, x}$ contained in the fiberwise $\delta_{0}$-neighborhood of $\mathfrak{Y}$ ) and containing the respective pairs of points $x, y$, etc. By Proposition $5.16, Y$ is $\delta_{5.16}(K, D, E)$-hyperbolic. The paths $c(x, y), c(y, z), c(z, x)$ are uniformly close to geodesics $[x y]_{L_{x, y}},[y z]_{L_{y, z}},[z x]_{L_{z, x}}$, which are $\kappa$-quasigeodesics in $Y$, where $\kappa$ depends only on $K, D$ and $E$. Therefore, by the $\delta_{5.16}(K, D, E)$-hyperbolicity of $Y$, for

$$
\epsilon=2 D_{1.53}\left(\delta_{5.16}(K, D, E), \kappa\right)+\delta_{5.16}(K, D, E)
$$

we have

$$
[x y]_{L_{x, y}} \subset N_{\epsilon}^{Y}\left([y z]_{L_{y, z}} \cup[z x]_{L_{z, x}}\right) \subset N_{\epsilon}\left([y z]_{L_{y, z}} \cup[z x]_{L_{z, x}}\right),
$$

where the first neighborhood is taken in $Y$ and the second is taken in $X$. Condition (a2) follows.

Lastly, by the construction, each $c(x, y)$ is uniformly close to an $L_{3.4}\left(K^{\prime}, D, E, \delta_{0}\right)$ quasigeodesic in $X$.

In the next corollary illustrates an application of Theorem 5.17 to proving hyperbolicity of various subspaces of $X$. As in Theorem 5.17, we assume that $k \geq k_{5.2}$, but set $K:=K_{5.2}\left(k^{\wedge}\right)$. We will use similar arguments in Section 6.1.2 to prove hyperbolicity of unions of pairs of flow-spaces. We refer to Definition 3.33 for the notion of a generalized flow-space, $F l_{k}(\mathfrak{Q})$, used below.

Corollary 5.20 (Hyperbolicity of generalized flow-spaces). Suppose that $\mathfrak{X}$ satisfies the uniform $\kappa_{4.5}(K)$-flaring condition. Then for every $k$-bundle $\mathfrak{Q}=(\pi: Q \rightarrow S) \subset \mathfrak{X}$, the $k$-flow space $F l_{k}(\mathfrak{Q})$ is $\delta_{5.20}(k)$-hyperbolic.

Proof. Pick $u \in V(S)$. Observe that every $x \in F l_{k}(\mathfrak{Q})$ is connected to $F l_{k}(\mathfrak{Q}) \cap X_{u}$ by a $k$-leaf $\gamma_{x}$. This leaf is contained in $F l_{k^{\wedge}}\left(Q_{u}\right)$ (see Proposition 3.26(2)). Therefore,

$$
F l_{k}(\mathfrak{Q}) \subset F l_{k^{\wedge}}\left(Q_{u}\right) .
$$

In view of the uniform flaring condition of the corollary, Theorem 5.17 applies to $F l_{k^{\wedge}}\left(Q_{u}\right)$ and, hence, the latter is $\delta_{5.17}\left(k^{\wedge}\right)$-hyperbolic. According to Theorem 3.34, $F l_{k}(\mathfrak{Q})$ is an $L_{3.34}(k, k)$-coarse Lipschitz retract of $X$. Hence $F l_{k}(\mathfrak{Q})$ is $\lambda(k)$-quasiconvex in $F l_{k^{\wedge}}\left(Q_{u}\right)$ and, therefore (in view of hyperbolicity of the latter), is $\delta_{5.20}(k)$-hyperbolic.

## CHAPTER 6

## Hyperbolicity of trees of spaces: Putting everything together

In this chapter we finish the proof of Theorem 2.58, establishing hyperbolicity of trees of hyperbolic spaces, satisfying the uniform $K$-flaring condition for suitable values of $K$. The key is to show hyperbolicity of flow-spaces $F l_{K}\left(X_{J}\right)$ for intervals $J \subset T$, Theorem 6.17. This is done in three steps:

Step 1. Hyperbolicity of $F l_{K}\left(X_{J}\right)$ for special intervals $J$ (Theorem 6.14). This is the hardest part of the chapter, we deal with it in Section 6.1. An outline of this part of proof is given in the introduction to Section 6.1.

Step 2. Hyperbolicity of $F l_{K}\left(X_{J}\right)$, when $J$ is the union of three special subintervals (Proposition 6.15).

Step 3. Hyperbolicity of $F l_{K}\left(X_{J}\right)$ for general intervals, which is done by subdividing $J$ as the union of subintervals $J_{i}$, each of which is a union of (at most) three special subintervals, and then using quasiconvex chain-amalgamation (Theorem 2.59).

Once we are done with Theorem 6.17, applying quasiconvex amalgamation (Corollary 2.63) one more time, in Proposition 6.18 we will prove that flow-spaces $F l_{K}\left(X_{S}\right)$ are uniformly hyperbolic, whenever $S$ is a tripod in $T$. We then conclude the proof of Theorem 2.58 by appealing to Corollary 1.64 one last time, by constructing a slim combing in $X$ via geodesics in flow-spaces of interval-spaces, see Section 6.3.

### 6.1. Hyperbolicity of flow-spaces of special interval-spaces

This section deals with Step 1 described in the introduction to the chapter. Recall that in Section 3.3 .5 we defined an interval $J=\llbracket u, v \rrbracket \subset T$ to be special (more precisely, $K$ special) if one of its end-points (say, $u$ ) has the property that $J \subset \pi\left(F l_{K}\left(X_{u}\right)\right)$. The main result of this section is Theorem 6.14, where we prove that the flow-space $F l_{K}\left(X_{J}\right)$ of every special interval $J \subset T$, is uniformly hyperbolic with hyperbolicity constant depending only on $K$. The fact that this is true is not at all surprising since, assuming that $X$ is hyperbolic, a uniform neighborhood of two intersecting uniformly quasiconvex subsets is uniformly qi embedded in $X$ and, hence, is uniformly hyperbolic. However, at this stage we did not yet prove hyperbolicity of $X$ and, furthermore, we are interested in describing uniform quasigeodesics in $X$. The most difficult part of the proof is to show that for each special interval $J$, a certain uniform (depending on $K$ ) neighborhood in $X$ of the union $F l_{K}\left(X_{u}\right) \cup$ $F l_{K}\left(X_{v}\right)$ is uniformly properly embedded in $X$ and uniformly hyperbolic (Corollary 6.11). The idea is to:
(i) embed such union in a larger "modified" flow-space

$$
F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{v}\right) \cup F l_{R}(\mathfrak{H})
$$

(for a certain $R=R(K)$ and a metric bundle $\mathfrak{G}$ over the interval $J=\llbracket u, v \rrbracket$ ),
(ii) prove uniform hyperbolicity of a uniform neighborhood of this triple union using quasiconvex amalgamation (Theorem 2.59),
(iii) lastly, use the fact that a uniform neighborhood of the union of intersecting quasiconvex subsets of a hyperbolic space is again uniformly quasiconvex and hyperbolic.

We then use quasiconvex amalgamation to prove the same result for the union of three flow-spaces

$$
F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{w}\right) \cup F l_{K}\left(X_{v}\right),
$$

where each subinterval $\llbracket u, w \rrbracket, \llbracket w, v \rrbracket$ is special. Theorem 6.14 is then proven by verifying that the family of paths in $F l_{K}\left(X_{J}\right)$ which are geodesics in pairwise unions $N_{D}\left(F l_{K}\left(X_{s}\right) \cup\right.$ $\left.F l_{K}\left(X_{t}\right)\right), s, t \in V(J)$, satisfy the slim combing axioms from Corollary 1.64.
6.1.1. Proper embeddings of unions of pairs of intersecting flow-spaces. Assuming that $F l_{K}\left(X_{u}\right) \cap X_{v} \neq \emptyset$, we will show that a certain uniform neighborhood of the union of two flow-spaces $F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{v}\right)$ is uniformly properly embedded in $X$. We first deal with the following easier case when $T$ is an interval, which we will identify with an interval $[0, n] \subset \mathbb{R}, n \in \mathbb{N}$, and that the vertex-set of $T$ equals to the set of integer points in the interval. Recall that $M_{k}$ is the parameter from the definition of uniform $k$-flaring (Definition 2.44).

Lemma 6.1. Suppose $\mathfrak{X}=(\pi: X \rightarrow T)$ is a tree of hyperbolic spaces, such that the tree $T$ is an interval $T=[0, n], K \geq K_{0}$ and $\mathfrak{\mathfrak { X } \text { satisfies the uniform } k \text { -flaring condition for }}$ $k=(L+1)^{2} K$, where $L=L_{3.21}(K)$. Assume, moreover, that for vertices $u, v \in V(T)$, and a $4 \delta_{0}$-quasiconvex subset $Q=Q_{u} \subset X_{u}$, we have $F l_{K}(Q) \cap X_{v} \neq \emptyset$.

Then the fiberwise $M_{k}$-neighborhood of $F l_{K}(Q) \cup F l_{K}\left(X_{n}\right)$ is uniformly properly embedded in $X$, with the distortion function depending only on $K$.

Proof. It suffices to show that for each $D>0$ and $x, y \in \mathcal{F} l_{K}(Q) \cup \mathcal{F} l_{K}\left(X_{v}\right)$ with $d(x, y)<D$, the intrinsic distance between $x$ and $y$ in the $M_{k}$-fiberwise neighborhood $U$ of $F l_{K}(Q) \cup F l_{K}\left(X_{v}\right)$ is bounded by a constant depending on $D, K$ only.

Claim 6.2. The statement of the lemma holds for $v=n$.
Proof. Without loss of generality $x \in \mathcal{F} l_{K}(Q) \backslash \mathcal{F} l_{K}\left(X_{n}\right)$ and $y \in \mathcal{F} l_{K}\left(X_{n}\right) \backslash F l_{K}(Q)$. (Otherwise, the claim follows from Theorem 3.21.) In the proof we will be repeatedly using Mitra's retractions $\rho$ defined in Theorem 3.21.

Reduction 1. We first reduce to the case where $x, y$ are in the same vertex-space and, moreover, $x=\rho_{F l_{k}(Q)}(y)$.

Observe that, since $T$ is an interval with an extremal vertex $n, y \in F l_{K}\left(X_{n}\right)$ and $F l_{K}\left(X_{u}\right) \cap X_{n} \neq \emptyset, \pi(y) \in \pi\left(F l_{K}(Q)\right)$. In particular, by the definition of Mitra's retraction $\rho_{F l_{K}(Q)}$,

$$
x^{\prime}:=\rho_{F l_{K}(Q)}(y) \in X_{\pi(y)} \cap \mathcal{F} l_{K}(Q)
$$

We also apply Mitra's retraction $\rho_{F l_{K}(Q)}: X \rightarrow F l_{K}(A)$ to $x y$, a geodesic in $X$ connecting $x$ to $y$. The image $\rho_{F l_{K}(Q)}(x y)$ is a path of length $\leq D_{1}:=(D+1) L_{3.21}(K)$ in $F l_{K}(Q)$ joining $x$ to $x^{\prime}$. Thus,

$$
d_{F l_{K}(Q)}\left(x, x^{\prime}\right) \leq D_{1}
$$

while $d\left(x^{\prime}, y\right) \leq d(x, y)+d\left(x^{\prime}, x\right) \leq D+D_{1}$. Hence, we replace $x$ by $x^{\prime}$ and, henceforth, assume that $x, y$ are in the same vertex-space and $d(x, y) \leq D$ (with $D:=D+D_{1}$ ). Note that $\pi(x) \neq n$ since $x \in F l_{K}(Q) \backslash F l_{K}\left(X_{n}\right)$.

We therefore, assume from now on that $j=\pi(x)=\pi(y)$ and $x=\rho_{F l_{K}(Q)}(y)$.

Reduction 2. We next reduce to the case when both $x, y$ are connected by $k$-qi leaves to the same point $z \in X_{n}$, where $k$ is as in the statement of lemma.

Let $\gamma_{y}$ be a $K$-qi in $F l_{K}\left(X_{n}\right)$ leaf joining $y$ to some $z \in X_{n}$. In view of the assumption that $x=\rho_{F l_{K}(Q)}(y)$, the path

$$
\bar{\gamma}_{x}:=\rho_{F l_{K}(Q)}\left(\gamma_{y}\right) \subset F l_{K}(Q)
$$

connects $x$ to $z_{1}=\bar{\gamma}_{x}(n)=\rho_{F l_{K}(Q)}(z) \in X_{n}$. For $y_{1}=\rho_{F l_{K}\left(X_{n}\right)}(x)$, the path

$$
\gamma_{y_{1}}:=\rho_{F l_{K}\left(X_{n}\right)} \circ \rho_{F l_{K}(Q)}\left(\gamma_{y}\right) \subset X_{n}
$$

also connects $y_{1}$ to $z_{1}$. Since both Mitra's retractions that we used are $L=L_{3.21}(K)$-coarse Lipschitz, the paths $\bar{\gamma}_{x}, \gamma_{y_{1}}$ are $k$-qi leaves for $k=(L+1)^{2} K$.

Observe that since projections of $F l_{K}(Q)$ and $F l_{K}\left(X_{n}\right)$ to $T$ both contain the interval $\llbracket j, n \rrbracket$, both Mitra's retractions restricted to the vertex spaces $X_{i}, i \in \llbracket j, n \rrbracket$, amount to fiberwise nearest-point projections to respective flow-spaces. In particular, $y_{1} \in X_{j}$.

We next estimate $d_{X_{j}}\left(y, y_{1}\right)$. Since $\rho_{F l_{K}\left(X_{n}\right)}$ is $L$-coarse Lipschitz, $\rho_{F l_{K}\left(X_{n}\right)}(y)=y$, $\rho_{F l_{K}\left(X_{n}\right)}(x)=y_{1}$ and $d(x, y) \leq D$, we obtain

$$
d_{F l_{K}\left(X_{n}\right)}\left(y, y_{1}\right) \leq(L+1) D .
$$

At the same time, $d\left(x, y_{1}\right) \leq d(x, y)+d\left(y, y_{1}\right) \leq 2 D$. Therefore, it suffices to prove the claim for the pair of points $x, y_{1}$ : Both are connected to $z_{1} \in X_{n}$ by $k$-leaves $\bar{\gamma}_{x} \subset F l_{K}(Q), \gamma_{y_{1}} \subset$ $F l_{K}\left(X_{n}\right)$ respectively. We now reset $z:=z_{1}, D:=2 D$.

Thus, we consider the case of points $x, y \in X_{j}$ such that $d(x, y) \leq D, x \in F l_{K}(Q) \cap$ $X_{j}, y \in F l_{K}\left(X_{n}\right) \cap X_{j}$ and there exist $k$-qi leaves $\gamma_{x}, \gamma_{y}$ in $F l_{K}(Q), F l_{K}\left(X_{n}\right)$, respectively, connecting $x, y$ to a point $z \in X_{n}$. Let $t \in \llbracket j, n \rrbracket$ be the minimal vertex such that

$$
d_{X_{t}}\left(\gamma_{x}(t), \gamma_{y}(t)\right) \leq M_{k} .
$$

(Such $t$ exists since $d_{X_{n}}\left(\gamma_{x}(n), \gamma_{y}(n)\right)=0$.) Recall that the vertex-spaces of $X$ are $\eta_{0^{-}}$ uniformly properly embedded in $X$; in particular, $d_{X_{j}}(x, y) \leq \eta_{0}(D)$.

If $d_{X_{j}}(x, y) \leq M_{k}$, we will be done by taking

$$
D_{6.1}(K):=M_{k},
$$

since the intrinsic distance between $x$ and $y$ in $U:=N_{M_{r}}^{f i b}\left(F l_{K}(Q) \cup F l_{K}\left(X_{n}\right)\right)$ would be $\leq d_{X_{j}}(x, y) \leq \eta_{0}(D)$.

Otherwise (if $d_{X_{j}}(x, y)>M_{k}$ ), by the uniform $k$-flaring condition, the length of the interval $\llbracket j, t \rrbracket$ is at most $\tau_{2.43}\left(k, \max \left(\eta_{0}(D), M_{k}\right)\right)$. Therefore, the intrinsic distance between $x, y$ in $U$ is at most

$$
k \tau_{2.43}\left(k, \max \left(\eta_{0}(D), M_{k}\right)\right)+M_{k} .
$$

This concludes the proof of the claim.
We return to the proof of the lemma and consider the general case, when $v$ need not be equal to the extreme vertex $n$ of $T=\llbracket 0, n \rrbracket$. Let $x \in X_{u_{0}}, y \in X_{v_{0}}$ be points within distance $D, u_{0}, v_{0} \in V(T)$. There are two cases to consider, depending on the order of the vertices $v, u_{0}$ in $\llbracket 0, n \rrbracket$.

1. Suppose that $v$ lies in the interval $\llbracket u, u_{0} \rrbracket$ (or $\left.\llbracket u_{0}, u \rrbracket\right)$. Since $x \in F l_{K}\left(X_{u}\right) \cap X_{u_{0}}$ Proposition 3.26 (specifically, (3.14) with $r=0$ ) implies that $x \in F l_{K}\left(X_{v}\right)$. Thus, $x, y$ both belong to $F l_{K}\left(X_{v}\right)$ and we conclude using the fact that flow-spaces are uniformly quasiisometrically embedded in $X$.
2. Suppose that $v$ does not lie in the interval between $u, u_{0}$ in $T$. Without loss of generality (reversing the orientation on $T$ if necessary), with respect to the order on the interval $T$,

$$
\max \left(u, u_{0}\right)<v .
$$

If $v_{0} \leq v$ then we can shorten the tree $T$ replacing it with the subinterval $\llbracket 0, v \rrbracket$ and reduce the problem to the one solved in the claim above. Thus, we can assume that

$$
0 \leq \max \left(u, u_{0}\right)<v<v_{0} \leq n .
$$

In particular, $d_{T}\left(u_{0}, v_{0}\right)=d_{T}\left(u_{0}, v\right)+d_{T}\left(v, v_{0}\right)$. By projecting a geodesic $x y$ in $X$ to the tree $T$, we see that $d_{T}\left(u_{0}, v_{0}\right) \leq D$ and, therefore,

$$
\max \left(d_{T}\left(u_{0}, v\right), d_{T}\left(v, v_{0}\right)\right) \leq D
$$

Hence, a $K$-qi leaf $\gamma_{y}$ in $F L_{K}\left(X_{v}\right)$ connecting $y$ to $y_{1} \in X_{v}$ has length $\leq K D$, which implies that

$$
d\left(y, y_{1}\right) \leq d_{F L_{K}\left(X_{v}\right)}\left(y, y_{1}\right) \leq(K+1) D .
$$

Consider the subtree $S=\llbracket 0, v \rrbracket$ in $T$. According to Lemma 2.17, the inclusion $X_{S} \rightarrow X$ is an $\eta=\eta_{2.17}$-uniformly proper map (where the function $\eta$ depends only on the parameters of the tree of spaces $\mathfrak{X}$ ). In particular,

$$
d_{X_{S}}\left(x, y_{1}\right) \leq D_{1}:=\eta((K+1) D)
$$

Thus, it suffices to estimate the distance $d_{X_{1}}\left(x, y_{1}\right)$ in the fiberwise $M_{k}$-neighborhood of $F l_{K}(Q) \cup F L_{K}\left(X_{v}\right) \cap X_{S}$. Since $v$ is an extreme vertex of $S$, this is done in the claim above. Lemma follows.

Lastly, we consider the case of a general tree $T$ :
Proposition 6.3. Suppose $\mathfrak{X}=(\pi: X \rightarrow T)$ is a tree of hyperbolic spaces, $K \geq K_{0}$ and $\mathfrak{X}$ satisfies the uniform $k$-flaring condition, where, as in the lemma,

$$
k=k_{6.3}(K)=(L+1)^{2} K, \quad L=L_{3.21}(K)
$$

Assume, moreover, that for some $4 \delta_{0}$-quasiconvex subset $Q=Q_{u} \subset X_{u}$, we have $F l_{K}(Q) \cap$ $X_{v} \neq \emptyset$. Then the $M_{k}$-neighborhood of $Y=F l_{K}(Q) \cup F l_{K}\left(X_{v}\right)$ in $X$ is $\eta_{6 \cdot 3, K}$-properly embedded in $X$.

Proof. Suppose

$$
x \in F l_{K}\left(X_{u}\right) \cap X_{u_{0}}, y \in F l_{K}\left(X_{v}\right) \cap X_{v_{0}}
$$

satisfy $d(x, y) \leq D$. We need to show that there is a constant constant $D_{1}>0$ depending only on $D$ and $K$ such that the distance between $x, y$ in $N_{M_{k}}(Y)$ is at most $D_{1}$.

If both $x, y$ are either in $F l_{K}\left(X_{u}\right)$ or $F l_{K}\left(X_{v}\right)$ then certainly this is true since $K$-flows of vertex-spaces are uniformly quasiisometrically embedded in $X$.

Suppose, therefore, that

$$
\begin{equation*}
x \in \mathcal{F} l_{K}\left(X_{u}\right) \backslash \mathcal{F} l_{K}\left(X_{v}\right) \text { and } y \in \mathcal{F} l_{K}\left(X_{v}\right) \backslash \mathcal{F} l_{K}\left(X_{u}\right) \tag{6.1}
\end{equation*}
$$

If $u, v$ span an edge in $T$ then our assumptions on the location of $x$ and $y$ imply that the set of vertices $\left\{u_{0}=\pi(x), v_{0}=\pi(y), u, v\right\}$ is contained in a common interval in $T$ and, hence, the claim follows from Lemma 6.1. Thus, we assume that $d_{T}(u, v) \geq 2$. More generally, we can assume that $u_{0}, v_{0}, u, v$ do not belong to a common interval in $T$.

The same assumption (6.1) implies that the center of $\Delta u_{0} u v \subset T$ is in $\llbracket u, v \llbracket$ and the center of $\Delta v_{0} u v$ is in $\rrbracket u, v \rrbracket$, and if these centers are equal, then they are in $\rrbracket u, v \llbracket$.

The proof of the proposition is broken in three cases:

Figure 18. Cases 2 and 3

Case 1: Suppose $x, y$ are in the same vertex-space $X_{t}$; we let $w$ denote the center of $\Delta u v t$. As noted before, $w \in \rrbracket u, v \llbracket$. Let $Q=Q_{w}=F l_{K}\left(X_{u}\right) \cap X_{w}$; this is a $4 \delta_{0}$-quasiconvex subset of $X_{w}$.

For the interval $S=\llbracket v, t \rrbracket$ consider the subtree of spaces $X_{S} \subset X$. The points $x, y$ belong to the $K$-flow-spaces $F l_{K}(Q), F l_{K}\left(X_{v}\right)$ in $X_{S}$, and

$$
\emptyset \neq F l_{K}\left(X_{u}\right) \cap X_{v} \subset F l_{K}(Q) \cap X_{v} .
$$

We also have $d_{X_{S}}(x, y) \leq \eta(D)$, where $\eta=\eta_{2.17}$. Thus, the conclusion follows from Lemma 6.1 applied to the tree of spaces $X_{S}$ over the interval $S$.

Case 2: Suppose the triangles $\Delta u_{0} u v$ and $\Delta v_{0} u v$ have the common center $w$, see Figure 18. Let $t$ denote the center of the triangle $\Delta w u_{0} v_{0}$. Without loss of generality, we may assume that $d_{T}(\pi(x), t) \leq d_{T}(\pi(x), \pi(y))$. Since $d(x, y) \leq D$, we also obtain $d_{T}\left(v_{0}, t\right) \leq D$. Let $\gamma_{x}, \gamma_{y}$ denote, respectively, $K$-qi leaves in $F l_{K}\left(X_{u}\right), F l_{K}\left(X_{v}\right)$ connecting $x$, $y$ to $X_{u}, X_{v}$. Then, for $x_{1}=\gamma_{x}(t)$ and $y_{1}=\gamma_{y}(t)$ we have

$$
d_{F l_{K}(Q)}\left(x, x_{1}\right) \leq K D \text { and } d_{F l_{K}\left(X_{v}\right)}\left(y, y_{1}\right) \leq K D .
$$

In particular $d\left(x_{1}, y_{1}\right) \leq(1+2 K) D$ and $x_{1}, y_{1}$ belong to the same vertex-space $X_{t}$. This reduces the proof to that of Case 1.

Case 3: Suppose the triangles $\Delta u_{0} u v$ and $\Delta v_{0} u v$ have distinct centers $u_{1}$ and $v_{1}$ respectively. These centers necessarily belong to the interval $\llbracket u, v \rrbracket$, see Figure 18. As in Case 2 we first we take two $K$-qi leaves $\gamma_{x}, \gamma_{y}$ in $F l_{K}\left(X_{u}\right), F l_{K}\left(X_{v}\right)$, connecting $x, y$ respectively to $X_{u}$ and $X_{v}$. Since $d(x, y) \leq D$, we also have $d_{T}\left(u_{0}, u_{1}\right) \leq D, d\left(v_{0}, v_{1}\right) \leq D$.

We then replace $x$ with $x_{1}=\gamma_{x}\left(u_{1}\right)$ and replace $y$ with $y_{1}=\gamma_{y}\left(v_{1}\right)$, which are within distance $K D$ from $x$, respectively $y$, in $F l_{K}\left(X_{u}\right), F l_{K}\left(X_{v}\right)$. Furthermore,

$$
d\left(x_{1}, y_{1}\right) \leq D(1+2 K)
$$

Since $x_{1}, y_{1}$ belong to the subtree of spaces $X_{u v}=\pi^{-1}(u v)$, analogously to Case 1 , we conclude the proof by applying Lemma 6.1.

Corollary 6.4. Suppose $\mathfrak{X}=(\pi: X \rightarrow T)$ is a tree of hyperbolic spaces, $K \geq K_{0}$ and $\mathfrak{X}$ satisfies the uniform $k$-flaring condition for

$$
k=k_{6.3}(K)
$$

Assume also that for a $4 \delta_{0}$-quasiconvex subset $Q=Q_{u} \subset X_{u}$, we have $F l_{K}(Q) \cap X_{v} \neq \emptyset$.
Then for each $r \geq M_{k}$, the $r$-neighborhood of $F l_{K}(Q) \cup F l_{K}\left(X_{v}\right)$ in $X$ is $\eta_{6.4, K, r}$-properly embedded in $X$.
6.1.2. Hyperbolicity of the union of two flow-spaces in the case of special intervals. The goal of this section is to prove that a uniform neighborhood of $F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{v}\right)$ in $X$ is uniformly hyperbolic, with the hyperbolicity constant depending only on $K$, provided that $F l_{K}\left(X_{u}\right) \cap X_{v} \neq \emptyset$ and $\mathfrak{X}$ satisfies a suitable uniform flaring condition.

Here is the idea of the proof. Recall that $F l_{K}\left(X_{u}\right)$ and $F l_{K}\left(X_{v}\right)$ are (uniformly) hyperbolic and are (uniformly) qi embedded in $X$. If $X$ were hyperbolic, it would follow (since $F l_{K}\left(X_{u}\right) \cap F l_{K}\left(X_{v}\right) \neq \emptyset$ ) that a uniform neighborhood of $F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{v}\right)$ is uniformly hyperbolic. Hyperbolicity of $X$, of course, is not yet proven, so instead, we will find (see the proof of Corollary 6.4) a larger subset $U=U_{r_{1}}$ containing $F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{v}\right)$, which is uniformly hyperbolic and uniformly properly embedded in $X$ (Proposition 6.10). Thus, a suitable uniform neighborhood of $F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{v}\right)$ in $U$ is uniformly hyperbolic and uniformly properly embedded in $U$. From this (since $U$ is uniformly properly embedded in $X$ ), we will conclude that a suitable uniform neighborhood of $F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{v}\right)$ in $X$ is also uniformly hyperbolic and uniformly properly embedded in $X$.

Lemma 6.5. For all $D \geq 0, K \geq K_{0}$ there is a constant $K_{6.5}=K_{6.5}(K) \geq K$ such that the following holds:

Let $u, v \in T$ be vertices such $F l_{K}\left(X_{u}\right) \cap X_{v} \neq \emptyset$. Then for each

$$
x \in N_{D}\left(\mathcal{F} l_{K}\left(X_{u}\right)\right) \cap N_{D}\left(\mathcal{F} l_{K}\left(X_{v}\right)\right),
$$

there is a vertex $t \in V(T)$ and a $K_{6.5}$ qi section $\Sigma$ of $\pi: X \rightarrow T$ over the tripod (triangle) $S=\Delta t u v$ such that

$$
x \in N_{3 D}\left(\Sigma \cap X_{t}\right)
$$

and

$$
\Sigma \subset F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{v}\right) .
$$

Proof. First of all, there is a vertex $t \in V(T)$ and points $x_{1} \in X_{t} \cap F l_{K}\left(X_{u}\right), x_{2} \in$ $X_{t} \cap F l_{K}\left(X_{v}\right)$ such that

$$
d_{X_{t}}\left(x, x_{i}\right) \leq D, i=1,2
$$

Let $\gamma_{1}$ be a $K$-qi leaf in $F l_{K}\left(X_{u}\right)$ connecting $x_{1}$ to $X_{u}$. We apply Mitra's projection $\rho=$ $\rho_{F l_{K}\left(X_{v}\right)}$ to $\gamma_{1}$; call the result $\gamma_{1}^{\prime}$. Since, by the assumption of the lemma,

$$
S \subset \pi\left(F l_{K}\left(X_{u}\right)\right),
$$

$\rho$ restricted to $X_{S}$ amounts to the fiberwise projection to $F l_{K}\left(X_{v}\right)$. In particular, $\pi\left(\gamma_{1}^{\prime}\right)=$ $\llbracket u, t \rrbracket$. Hence, $\gamma_{1}^{\prime}$ is a $K_{6.5}:=K L_{3.21}(K)$-qi section over $\llbracket u, t \rrbracket$ whose image is contained in $F l_{K}\left(X_{v}\right)$.

Let $w \in u v$ denote the center of the triangle $S$. Since $\gamma_{1}^{\prime}$ is contained in $F l_{K}\left(X_{v}\right)$, the point $\gamma_{1}^{\prime}(w)$ can be joined to $X_{v}$ by a $K$-qi leaf $\gamma_{2}^{\prime}$ inside $F l_{K}\left(X_{v}\right)$. Clearly, the union of these two qi leaves $\gamma_{1}^{\prime} \cup \gamma_{2}^{\prime}$ forms a $K_{6.5}$-qi section $\Sigma$ over the tripod $S$.

We have

$$
\begin{aligned}
& d_{X_{t}}\left(x_{1}, \gamma_{1}^{\prime}(t)\right) \leq d_{X_{t}}\left(x_{1}, x_{2}\right) \leq 2 D \\
& d\left(x, x_{1}\right) \leq D, \quad d\left(x, \gamma_{1}^{\prime}(t)\right) \leq 3 D
\end{aligned}
$$

Lemma follows.
Set

$$
\begin{equation*}
k=K_{6.5}(K) \tag{6.2}
\end{equation*}
$$

and define $\mathcal{S}=\mathcal{S}_{k, J}$, the set of all $k$-qi sections over the interval $J=\llbracket u, v \rrbracket$.
Assuming that $F l_{K}\left(X_{u}\right) \cap X_{v} \neq \emptyset$ (which is the standing assumption of the previous and this section), $\mathcal{S}$ is nonempty since $k \geq K$ and we are assuming that

$$
F l_{K}\left(X_{u}\right) \cap X_{v} \neq \emptyset .
$$

For each vertex $w \in V(J)$, let $H_{w}$ denote the (fiberwise) $\delta_{0}$-hull of the subset $\{\gamma(w): \gamma \in \mathcal{S}\}$ in $X_{w}$. Define

$$
\mathcal{H}:=\bigcup_{w \in V(J)} H_{w} .
$$

Each $H_{w}$, of course, is a $4 \delta_{0}$-quasiconvex subset of $X_{w}$. Then Lemma 3.17(b) implies that $\mathcal{H}$ is the union of vertex-spaces of a $k^{\prime}=K_{3.17}^{\prime}(k)$-metric bundle $\mathfrak{G}=\mathfrak{G}_{k, J}$ over the interval $J$, see Definition 3.5.

As in Section 3.3.3, we define the generalized $\kappa$-flow-spaces $F l_{\kappa}(\mathfrak{G})$ of the metric bundle $\mathfrak{H}$. From the definition, we recall that with each vertex $w \in V(J)$ we associate a subtree $T_{w} \subset T$ equal to the maximal subtree in $T$ containing $w$ and disjoint from all other vertices of the interval $J$.

Below we will frequently use the function

$$
\kappa \mapsto \kappa^{\wedge}=\left(15 L_{0}^{\prime} \kappa\right)^{3},
$$

defined in (3.11).
Lemma 6.6. For $D \geq 0, K \geq K_{0}$ set $k=K_{6.5}(K), k^{\prime}=K_{3.17}^{\prime}(k)$. Then the following hold:
(1) Suppose that

$$
x \in N_{D}\left(\mathcal{F} l_{K}\left(X_{u}\right)\right) \cap N_{D}\left(\mathcal{F} l_{K}\left(X_{v}\right)\right)
$$

Then there exists a vertex $t \in V(T)$ with

$$
d\left(x, \mathcal{F} l_{K}\left(X_{u}\right) \cap \mathcal{F} l_{K}\left(X_{v}\right) \cap X_{t}\right) \leq D,
$$

such that the center w of $\Delta u v t$ satisfies

$$
x \in N_{3 D}\left(F l_{k^{\wedge}}\left(H_{w}\right) \cap X_{T_{w}}\right) .
$$

In other words, we have

$$
N_{D}\left(\mathcal{F} l_{K}\left(X_{u}\right)\right) \cap N_{D}\left(\mathcal{F} l_{K}\left(X_{v}\right)\right) \subset \bigcup_{w \in V(\llbracket u, v \|)} N_{3 D}\left(F l_{k^{\wedge}}\left(H_{w}\right) \cap X_{T_{w}}\right) .
$$

(2) For each $\kappa \geq k^{\prime}$ and each vertex $w \in V(\llbracket u, v \rrbracket)$ we have

$$
F l_{\kappa}\left(H_{w}\right) \cap X_{T_{w}} \subset F l_{\kappa^{\wedge}}\left(X_{u}\right) \cap F l_{\kappa^{\wedge}}\left(X_{v}\right) .
$$

In other words,

$$
F l_{\kappa}(\mathfrak{H}) \subset F l_{\kappa^{\wedge}}\left(X_{u}\right) \cap F l_{\kappa^{\wedge}}\left(X_{v}\right) .
$$

Proof. (1) By Lemma 6.5 there is a $k=K_{6.5}(K)$-qi section $\Sigma$ over a tripod $u v \cup w t$ such that

$$
d(x, \Sigma) \leq 3 D
$$

In particular, $\Sigma$ restricted to $J=\llbracket u, v \rrbracket$ is a $k$-qi section over $J$ hence, belongs to $\mathcal{S}_{k, J}$. Therefore, by the definition of $\mathcal{H}$, for the vertex $w \in V(J)$, the intersection $\Sigma \cap X_{w}$ belongs to $H_{w}$.

Since $\Sigma(w)$ is in $H_{w}$, the restriction of $\Sigma$ to the interval $\llbracket t, w \rrbracket$ is a $k$-qi leaf connecting $\Sigma \cap X_{t}$ to $H_{w}$ and, by Proposition 3.26(2),

$$
\Sigma \cap X_{t} \in F l_{k^{\wedge}}\left(H_{w}\right) .
$$

Thus,

$$
x \in N_{3 D}\left(F l_{k^{\wedge}}\left(H_{w}\right)\right) \cap X_{t} .
$$

This proves Part (1) for fiberwise neighborhoods. The proof for neighborhoods taken in $X$ is identical and we omit it.
(2) Given $x \in \mathcal{F} l_{\kappa}\left(H_{w}\right) \cap X_{T_{w}}$, pick a $\kappa$-qi leaf $\gamma_{x}$ in the flow-space $F l_{\kappa}\left(H_{w}\right)$ connecting $x$ to $H_{w}$.

Since $z=\gamma_{x}(w) \in H_{w}$, and $\mathfrak{G}$ is a $k^{\prime}$-metric bundle over the interval $J=\llbracket u, v \rrbracket$, there exists a $k^{\prime}$-qi leaf $\gamma_{z}$ in this bundle (over $\left.\llbracket w, v \rrbracket\right)$ connecting $z$ to $X_{v}$. Thus, since $\kappa \geq k^{\prime}$, the point $x$ can be connected to both $X_{u}$ and $X_{v}$ by $\kappa$-qi leaves. According to Proposition 3.26(2),

$$
x \in F l_{\kappa^{\wedge}}\left(X_{u}\right) \cap F l_{\kappa^{\wedge}}\left(X_{v}\right) .
$$

For the rest of this section (until Corollary 6.4) we will be working under the following assumption (which is stronger than the one we had earlier):

- We assume that $X_{v} \cap F l_{K}\left(X_{u}\right) \neq \emptyset, X_{u} \cap F l_{K}\left(X_{v}\right) \neq \emptyset$.

Remark 6.7. 1. This assumption implies that for all vertices $w \in V(\llbracket u, v \rrbracket)$,

$$
X_{w} \cap F l_{K}\left(X_{u}\right) \neq \emptyset, X_{w} \cap F l_{K}\left(X_{v}\right) \neq \emptyset .
$$

2. The stronger assumption we are now making is not too far from the condition that $X_{v} \cap F l_{K}\left(X_{u}\right) \neq \emptyset$ made earlier, since

$$
X_{u} \cap F l_{K^{\wedge}}\left(X_{v}\right) \neq \emptyset,
$$

see Proposition 3.26(2). We will be using this fact in the proof of Corollary 6.4.

We now fix some $K \geq K_{0}$, set, $k=K_{6.5}(K)$ and take some $R \geq k^{\wedge}$. For an interval $J=\llbracket u, v \rrbracket \subset T$, set $\mathfrak{G}:=\mathfrak{G}_{k, J}$ and $Y^{0}:=F l_{R}(\mathfrak{H})$. Since $\mathfrak{F} l_{R}(\mathfrak{H})$ is a generalized flow-space with the parameters $K_{1}=k^{\prime}$ and $K_{2}=R \geq K_{0}$, the next lemma is a corollary of Theorem 3.34:

Lemma 6.8. The inclusion map $Y^{0} \rightarrow X$ is a $L_{3.34}\left(k^{\prime}, R\right)$-qi embedding.
We also define the unions $Y^{1}=F l_{K}\left(X_{u}\right) \cup F l_{R}(\mathfrak{H}), Y^{2}=F l_{K}\left(X_{v}\right) \cup F l_{R}(\mathfrak{H})$ and their neighborhoods $U_{r}^{i}:=N_{r}\left(Y^{i}\right), i=1,2$, taken in $X$.

Lemma 6.9. For every $r \geq 0$,

$$
F l_{R}(\mathfrak{H}) \subset U_{r}^{1} \cap U_{r}^{2} \subset N_{3 r}\left(F l_{R}(\mathfrak{H})\right),
$$

i.e. the intersection is uniformly (in terms of $r, R$ and $K$ ) Hausdorff-close to $F l_{R}(\mathfrak{H})$.

Proof. Consider $x \in U_{r}^{1} \cap U_{r}^{2}$. Thus, there exist points $x_{1} \in F l_{K}\left(X_{u}\right) \cup F l_{R}(\mathfrak{H})$, $x_{2} \in F l_{K}\left(X_{v}\right) \cup F l_{R}(\mathfrak{H})$ at distance $\leq r$ from $x$. If one of these points is in $F l_{R}(\mathfrak{H})$ then $d\left(x, F l_{R}(\mathfrak{H})\right) \leq r$. Therefore, assume that $x_{1} \in F l_{K}\left(X_{u}\right), x_{2} \in F l_{K}\left(X_{v}\right)$. By Lemma 6.6(1), $d\left(x, F l_{R}(\mathfrak{H})\right) \leq 3 r$, as required.

Recall that $K \geq K_{0}, k=K_{6.5}(K)$. Set $R:=k^{\wedge}$. In the next proposition, $N^{\prime}$ indicates a metric neighborhood of $Y_{1}$ or $Y_{2}$ taken inside $F l_{R^{\wedge}}\left(X_{u}\right)$ or $F l_{R^{\wedge}}\left(X_{v}\right)$ respectively. The most useful part of the proposition is (2): Part (1) is used only to prove (2).

Proposition 6.10. Assume that $K \geq K_{0}$ and $\mathfrak{X}$ satisfies the uniform $\kappa$-flaring condition for

$$
\kappa=\max \left(k_{6.3}(K), \kappa_{4.5}\left(R^{\wedge}\right)\right)
$$

Then there exist $\delta_{6.10}^{\prime}=\delta_{6.10}^{\prime}(K, C), \delta_{6.10}=\delta_{6.10}(K), L_{6.10}^{\prime}=L_{6.10}^{\prime}(K, C), C_{6.10}=C_{6.10}(K)$, and a function $\eta_{6.10}=\eta_{6.10, K}$ such that the following hold.
(1) For each $C \geq C_{6.10}$, both $U_{1}^{\prime}=N_{C}^{\prime}\left(Y^{1}\right)$ and $U_{2}^{\prime}=N_{C}^{\prime}\left(Y^{2}\right)$, equipped with the induced path-metrics, are $\delta_{6.10}^{\prime}(K, C)$-hyperbolic and $L_{6.10}^{\prime}(K, C)$-qi embedded in $X$.
(2) For

$$
r:=\max \left(C_{6.10}, M_{k_{6.3}(K)}\right),
$$

the union

$$
U_{r}:=U_{r}^{1} \cup U_{r}^{2}
$$

equipped with the induced path-metric, is $\delta_{6.10}(K, R)$-hyperbolic and $\eta_{6.10}$-uniformly properly embedded in $X$.
Proof. (1) We will only prove the claim for $U_{1}^{\prime}$ since the proof for $U_{2}^{\prime}$ is obtained by relabelling. Recall that

$$
Y^{1}=F l_{K}\left(X_{u}\right) \cup Y^{0}
$$

Since $R \geq k^{\prime}$, the definition of $Y^{0}$ and Lemma 6.6(2) imply that

$$
Y^{0}=F l_{R}(\mathfrak{H}) \subset F l_{R^{\wedge}}\left(X_{u}\right) .
$$

Furthermore, since $R^{\wedge} \geq R \geq k \geq K, F l_{K}\left(X_{u}\right) \subset F l_{R^{\wedge}}\left(X_{u}\right)$. Thus,

$$
Y^{1} \subset F l_{R^{\wedge}}\left(X_{u}\right)
$$

Recall that we are assuming that $\mathfrak{X}$ satisfies the uniform $\kappa_{4.5}\left(R^{\wedge}\right)$-flaring condition. Therefore, Theorem 5.17 applies and the flow-space $F l_{R^{\wedge}}\left(X_{u}\right)$ is $\delta=\delta_{5.17}\left(R^{\wedge}\right)$-hyperbolic.

By Lemma $6.8, Y^{0}$ is $L_{3.34}\left(k^{\prime}, R\right)$-qi embedded in $X$, while $F l_{K}\left(X_{u}\right)$ is $L_{3.22}(K)$-qi embedded in $X$ according to Corollary 3.22.

Hence, for

$$
L:=2 \max \left(L_{3.34}\left(k^{\prime}, R\right), L_{3.22}(K)\right)
$$

and

$$
\lambda=\lambda_{1.90}(\delta, L)
$$

both $Y^{0}$ and $F l_{K}\left(X_{u}\right)$ are $\lambda$-quasiconvex in $F l_{R^{\wedge}}\left(X_{u}\right)$. Moreover, these subsets have nonempty intersection (containing at least $H_{u}$ ). Thus, their union is $\lambda+\delta$-quasiconvex in $F l_{R^{\wedge}}\left(X_{u}\right)$.

By Lemma 1.95(1), since

$$
C \geq C_{6.10} \geq \lambda+\delta,
$$

the $C$-neighborhood $U_{1}^{\prime}$ of $Y^{1}=F l_{K}\left(X_{u}\right) \cup Y^{0}$ in $F l_{R^{\wedge}}\left(X_{u}\right)$ (equipped with the induced path-metric) is $\delta+C$-quasiconvex in $F l_{R^{\wedge}}\left(X_{u}\right)$.

Furthermore, by Part (2) of the same lemma, since $C$ was taken to be $\geq 2 \lambda+4 \delta$, the inclusion map $U_{1}^{\prime} \rightarrow F l_{R^{\wedge}}\left(X_{u}\right)$ is a $(1,6 \delta+C)$-quasiisometric embedding, where $U_{1}^{\prime}$ is
equipped with the induced path-metric. Thus, $U_{1}^{\prime}$ is $\delta_{1.55}(\delta, 6 \delta+C)$-hyperbolic, see Lemma 1.55. Moreover, the inclusion map $U_{1}^{\prime} \rightarrow X$ is an $L_{6.10}^{\prime}$-qi embedding with

$$
L_{6.10}^{\prime}=L_{3.22}\left(R^{\wedge}\right)(6 \delta+C)
$$

This proves Part (1), where we use:

$$
\begin{array}{r}
\delta=\delta_{5.17}\left(R^{\wedge}\right), L=2 \max \left(L_{3.34}\left(k^{\prime}, R\right), L_{3.22}(K)\right), \\
\lambda=\lambda_{1.90}(\delta, L), C_{6.10}=2 \lambda+4 \delta, \delta_{6.10}^{\prime}=\delta_{1.55}(\delta, 6 \delta+C) .
\end{array}
$$

(2) In the proof of Part (1) we were using hyperbolicity of the union of two quasiconvex subsets in a hyperbolic space. In Part (2), such ambient hyperbolic space is unavailable, so we will use hyperbolicity of pairwise quasiconvex amalgams of hyperbolic spaces (Theorem 2.59, quasiconvex amalgamation), to prove hyperbolicity of $U_{r}$. We will be using Part (1) with $C=r$. We have, of course,

$$
Y_{i} \subset U_{i}^{\prime}=N_{r}^{\prime}\left(Y_{i}\right) \subset U_{r}^{i}=N_{r}\left(Y_{i}\right), i=1,2 .
$$

Since each inclusion map $U_{i}^{\prime} \rightarrow U_{r}^{i}$ is an $L$-quasiisometry, $L^{\prime}=\max \left(L_{3.22}(K), r\right)$, Lemma 1.55 implies that $U_{r}^{i}$ is $\delta_{1.55}^{\prime}\left(\delta_{6.10}^{\prime}, L^{\prime}\right)$-hyperbolic.

Since $Y^{0}$ is $L_{3.34}\left(k^{\prime}, R\right)$-qi embedded in $X$, it is $\lambda_{1.90}\left(\delta_{6.10}^{\prime}, L_{3.34}\left(k^{\prime}, R\right)\right.$ )-quasiconvex in $U_{r}^{i}, i=1$, 2. Since $Y^{0}$ is $3 r$-Hausdorff close to $U_{r}^{1} \cap U_{r}^{2}$ (Lemma 6.9), it follows that $U_{r}^{1} \cap U_{r}^{2}$ is $\lambda^{\prime}$-quasiconvex in both $U_{r}^{1}, U_{r}^{2}$ where

$$
\lambda^{\prime}=3 r+\delta_{6.10}^{\prime} \lambda_{1.90}\left(\delta_{6.10}^{\prime}, L_{3.34}\left(k^{\prime}, R\right)\right) .
$$

Thus, we are in position to apply Theorem 2.59 (quasiconvex amalgams), and conclude that the union $U_{r}=U_{r}^{1} \cup U_{r}^{2}$ is $\delta_{6.10}(K, D, R)$-hyperbolic. It remains to prove that $U_{r}$ is uniformly properly embedded in $X$, thereby proving half of (2).

Let $x_{1}, x_{2}$ be points in $U_{r}$. We need to estimate $d_{U_{r}}\left(x_{1}, x_{2}\right)$ in terms of $d\left(x_{1}, x_{2}\right)$. It suffices to consider the case when $x_{i} \in U_{r}^{i}, i=1,2$, since $U_{1}^{\prime}, U_{2}^{\prime}$ are both $L_{6.10}^{\prime}$-qi embedded in $X$ and are within Hausdorff distance $r$ from $U_{r}^{1}, U_{r}^{2}$ respectively. Let $y_{i} \in Y^{i}$ be points at distance $\leq r$ from $x_{i}, i=1,2 ; d\left(y_{1}, y_{2}\right) \leq d\left(x_{1}, x_{2}\right)+2 r$. Since $Y^{1}=F l_{K}\left(X_{u}\right) \cup Y^{0}, Y^{2}=$ $F l_{K}\left(X_{v}\right) \cup Y^{0}$, using the fact that $Y^{0}$ is $L_{3.34}\left(k^{\prime}, R\right)$-qi embedded in $X$, the problem reduces to the case when $y_{1} \in F l_{K}\left(X_{u}\right), y_{2} \in F l_{K}\left(X_{v}\right)$. Recall that according to Corollary 6.4 (applied to $Q_{u}=X_{u}$ ), since

$$
r \geq M_{k_{6,3}(K)},
$$

the $r$-neighborhood of the union $F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{v}\right)$ is $\eta_{6.4, K}$-properly embedded in $X$. Therefore,

$$
N_{r}\left(F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{v}\right)\right) \subset N_{r}\left(Y^{1}\right) \cup N_{r}\left(Y^{2}\right)=U_{r}
$$

and we obtain

$$
d_{U_{r}}\left(x_{1}, x_{2}\right) \leq d_{N_{M_{k}}\left(F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{v}\right)\right)} \leq \eta_{6.3, K}\left(d\left(x_{1}, x_{2}\right)+2 r\right) .
$$

This concludes the proof of Part (2) and, hence, of the proposition.
We can now prove the main result of this section:
Corollary 6.11. Suppose that $K \geq K_{0}$ and $u$, v are vertices in $T$ such that $F l_{K}\left(X_{u}\right) \cap$ $X_{v} \neq \emptyset$. Set $k_{6.11}:=K_{6.5}\left(K^{\wedge}\right), R_{6.11}:=k_{6.11}^{\wedge}$ and assume that $\mathfrak{X}$ satisfies the uniform $\kappa$-flaring condition for

$$
\kappa=\kappa_{6.11}(K)=\max \left(k_{6.3}\left(K^{\wedge}\right), \kappa_{4.5}\left(R_{6.11}^{\wedge}\right)\right)
$$

Then there exist $\delta=\delta_{6.11}(K), D=D_{6.11}(K)$, and a function $\eta=\eta_{6.11, K}$ such that the following hold:

The D-neighborhood $N_{D}\left(F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{\nu}\right)\right)$ (with the induced path-metric) in $X$ is $\delta$-hyperbolic and $\eta$-properly embedded in $X$.

Proof. According to Proposition 3.26, for $K_{1}=K^{\wedge}$,

$$
F l_{K_{1}}\left(X_{v}\right) \cap X_{u} \neq \emptyset .
$$

Of course, we still have

$$
F l_{K_{1}}\left(X_{u}\right) \cap X_{v} \supset F l_{K}\left(X_{u}\right) \cap X_{v} \neq \emptyset
$$

Therefore, Proposition 6.10(2) applies and we get that for $r_{1}=r\left(K_{1}\right)$ as in the proposition, $U=U_{r_{1}}$ is $\delta\left(K_{1}\right)$-hyperbolic and $\eta_{K_{1}}$-properly embedded in $X$.

Since both $F l_{K}\left(X_{u}\right), F l_{K}\left(X_{v}\right)$ are $L=L_{3.22}(K)$-qi embedded in $X$ (hence, in $U$ ), they are $\lambda_{1}=\lambda_{1.90}\left(\delta\left(K_{1}\right), L\right)$-quasiconvex in $U$ (Lemma 1.90). Set

$$
D:=\max \left(2 \lambda_{1}+4 \delta\left(K_{1}\right), M_{k_{6.3}(K)}\right)
$$

By Lemma 1.95, the $D$-neighborhood $V$ of $F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{v}\right)$ in $U$ is $\left(2 \lambda_{1}+5 \delta\left(K_{1}\right)\right)$ quasiconvex in $U$. By the same lemma, $V$ (equipped with its path-metric) is $\left(10 \delta\left(K_{1}\right)+\right.$ $2 \lambda_{1}$ )-qi embedded in $U$. Hence, $V$ is $\delta_{1.55}\left(\delta\left(K_{1}\right), 10 \delta\left(K_{1}\right)+2 \lambda_{1}\right.$ )-hyperbolic (see Lemma 1.55).

Note that the Hausdorff distance in $X$ between $V$ (the $D$-neighborhood of $F l_{K}\left(X_{u}\right) \cup$ $F l_{K}\left(X_{v}\right)$ in $U$ ) and $N_{D}\left(F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{v}\right)\right)$ (the $D$-neighborhood in $X$ ) is $\leq D$. Since $U$ is $\eta_{K_{1}}$-properly embedded in $X$ and the inclusion map $V \rightarrow U$ is a $\left(10 \delta\left(K_{1}\right)+2 \lambda_{1}\right)$-qi embedding, the composition $V \rightarrow N_{D}\left(F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{v}\right)\right)$ is $\zeta$-proper for

$$
\zeta(t)=\left(10 \delta\left(K_{1}\right)+2 \lambda_{1}\right) \eta(t)+\left(10 \delta\left(K_{1}\right)+2 \lambda_{1}\right)^{2} .
$$

Corollary 1.59 now implies that $N_{D}\left(F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{v}\right)\right)$ is $\delta_{6.11}(K)$-hyperbolic for

$$
\delta_{6.11}(K)=\delta_{1.55}\left(\delta_{1.55}\left(\delta\left(K_{1}\right), 10 \delta\left(K_{1}\right)+2 \lambda_{1}\right), \zeta(2 D+1)\right)
$$

It remains to estimate the distortion of $N_{D}\left(F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{v}\right)\right)$ in $X$. Since $D \geq M_{k_{6.3}(K)}$, Corollary 6.4 applies and $F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{v}\right)$ is $\eta_{6.4, K, D}$-properly embedded in $X$. Therefore, its $D$-neighborhood is $\eta$-properly embedded in $X$ for

$$
\eta_{6.11, K}(t)=\eta(t)=2 D+\eta_{6.4, K, D}(t+2 D)
$$

Remark 6.12. This corollary gives us the value of $K_{*}$ in Theorem 2.58:

$$
\begin{equation*}
K_{*}=\max \left(k_{6.3}\left(K^{\wedge}\right), \kappa_{4.5}\left(R_{6.11}^{\wedge}\right)\right), \tag{6.3}
\end{equation*}
$$

where $K=K_{0}$.
6.1.3. Hyperbolicity of flow-spaces of special interval-spaces $F l_{K}\left(X_{J}\right)$. In this section we conclude the proof of Theorem 6.14. We will also prove uniform hyperbolicity of flow-spaces $F l_{K}\left(X_{J}\right)$, whenever $J \subset T$ is a union of three special intervals.

For the next proposition, set $D=D_{6.11}(K)$ and $\kappa=\kappa_{6.11}(K)$.
Proposition 6.13. Assume that $K \geq K_{0}$ and $\mathfrak{X}$ satisfies the uniform $\kappa$-flaring condition. Let $v_{0}, v_{1}, v_{2}$ be vertices of $T$ such that $v_{0} \in \llbracket v_{1}, v_{2} \rrbracket$. We will assume that each subinterval $J_{i}=\llbracket v_{0}, v_{i} \rrbracket, i=1,2$, is special. Then the D-neighborhood (taken in $X$ )

$$
Z:=N_{D}\left(F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{v}\right) \cup F l_{K}\left(X_{w}\right)\right)
$$

(equipped with the path-metric induced from $X$ ) is $\delta=\delta_{6.13}(K)$-hyperbolic and $\eta=\eta_{6.13, K^{-}}$ properly embedded in $X$.

Proof. Define $Y_{i}=N_{D}\left(F l_{K}\left(X_{v_{i}}\right)\right), Z_{i}:=N_{D}\left(Y_{0} \cup Y_{i}\right), i=0,1,2$. Thus, $Z=N_{D}\left(Y_{1} \cup Y_{2}\right)$ and, furthermore, $N_{D}\left(Y_{0}\right)=Z_{0}=Z_{1} \cap Z_{2}$ and $Z_{0}$ separates $Z_{1}, Z_{2}$ in $X$ : Every path $c$ connecting a point of $Z_{1}$ to a point of $Z_{2}$, has to intersect $Z_{0}$, see Proposition 3.26(1).

1: $Z=Z_{1} \cup Z_{2}$ is hyperbolic. The hypothesis of the proposition implies that both $Z_{1}$ and $Z_{2}$ satisfy the assumptions of Corollary 6.11 . Thus, each $Z_{i}$ is $\delta_{6.11}(K)$-hyperbolic and $\eta_{6.11, K}$-properly embedded in $X$. Since $F l_{K}\left(X_{v_{0}}\right)$ is $L_{3.22}(K)$-qi embedded in $X$, it is $\lambda=\lambda_{1.90}\left(\delta_{6.11}(K), L_{3.22}(K)\right)$-quasiconvex in $Z_{1}, Z_{2}$. Hence, $Z_{0}=N_{D}\left(F l_{K}\left(X_{v_{0}}\right)\right)$ is $\lambda+D+$ $2 \delta_{6.11}(K)$-quasiconvex in $Z_{1}, Z_{2}$. Theorem 2.59 (for quasiconvex amalgams) now implies that $Z$ is $\delta=\delta_{6.13}(K)$-hyperbolic.

2: $Z_{1} \cup Z_{2}$ is uniformly properly embedded in $X$. The proof is similar to that of Proposition $6.10(2)$. Take points $x_{1} \in Z_{1}, x_{2} \in Z_{2}$. Then the separation property mentioned earlier, implies that each geodesic $z_{1} z_{2}$ in $X$ has to intersect $Z_{0}$ at some $z_{0}$. In particular, $\max \left(d\left(z_{1}, z_{0}\right), d\left(z_{0}, z_{2}\right)\right) \leq d\left(z_{1}, z_{2}\right)$.

By Proposition 6.3, for $i=1,2$,

$$
d_{Z_{i}}\left(z_{i}, z_{0}\right) \leq 2 D+\eta_{6.3, K}\left(d\left(z_{i}, z_{0}\right)\right) \leq 2 D+\eta_{6.3, K}\left(d\left(z_{1}, z_{2}\right)\right),
$$

and, therefore,

$$
d_{Z}\left(z_{1}, z_{2}\right) \leq \eta\left(d\left(z_{1}, z_{2}\right)\right)=\eta_{6.13, K}\left(d\left(z_{1}, z_{2}\right)\right):=4 D+2 \eta_{6.3, K}\left(d\left(z_{1}, z_{2}\right)\right)
$$

Recall that for subtrees $S \subset T$, we defined flow-spaces $F l_{K}\left(X_{S}\right)$, see (3.16). We again assume that $K \geq K_{0}$, $\mathfrak{X}$ satisfies the uniform $\kappa_{6.11}(K)$-flaring condition and set $D=$ $D_{6.11}(K)$.

Theorem 6.14. The flow-space $F l_{K}\left(X_{J}\right)$ of any special interval $J=\llbracket u, v \rrbracket \subset T$ (equipped with the intrinsic path-metric) is $\delta_{6.14}(K)$-hyperbolic.

Proof. It suffices to prove uniform hyperbolicity of the $D$-neighborhood of $F l_{K}\left(X_{J}\right)$ in $X$ (with the path-metric induced from $X$ ), the claim then will follow from the fact that $F l_{K}\left(X_{J}\right)$ is uniformly qi-embedded in $X$ (Proposition 3.32).

Note that, in view of the assumption of the theorem, for any two vertices $t, s \in J$, at least one of the intersections is nonempty:

$$
F l_{K}\left(X_{t}\right) \cap X_{s} \neq \emptyset, \quad \text { or } \quad F l_{K}\left(X_{s}\right) \cap X_{t} \neq \emptyset
$$

(depending on which distance $d(t, v), d(s, v)$ is larger). Thus, any triple of vertices $v_{0}, v_{1}, v_{2} \in$ $J$ satisfies the assumptions of Proposition 6.13, and, hence,

$$
Z=N_{D}\left(F l_{K}\left(X_{v_{0}}\right) \cup F l_{K}\left(X_{v_{1}}\right) \cup F l_{K}\left(X_{v_{2}}\right)\right)
$$

is $\delta_{6.13}(K)$-hyperbolic and $\eta_{6.13, K}$-properly embedded in $X$. Since each flow-space $F l_{K}\left(X_{v_{i}}\right)$ is $L_{3.22}(K)$-qi embedded in $X$, it follows that the $D$-neighborhood of the union of any two of these flow-spaces is $\lambda(K)$-quasiconvex in $Z$.

We are now in position to apply Corollary 1.64. For each pair of points $x, y \in \mathcal{F} l_{K}\left(X_{I}\right)$ we define the path $c(x, y)$ in $N_{D}\left(F l_{K}\left(X_{J}\right)\right)$ to be a geodesic between $x, y$ in

$$
N_{D}\left(F l_{K}\left(X_{\pi(x)}\right) \cup F l_{K}\left(X_{\pi(y)}\right)\right)
$$

In view of the uniform proper embeddedness of this union (in $X$ ) and the uniform hyperbolicity of the triple unions as above, this family of paths in $F l_{K}\left(X_{J}\right)$ satisfies axioms of Corollary 1.64.

We now deal with Step 2 outlined in the introduction to this chapter. This step is a rather direct application of Theorem 6.14: We apply quasiconvex amalgamation of pairs twice to show that $F l_{K}\left(X_{J}\right)$ is hyperbolic.

Proposition 6.15. Suppose that $J$ is an interval in $T$, that can be subdivided as a union of three special subintervals $J=J_{1} \cup J_{2} \cup J_{3}$,

$$
J_{i}=\llbracket v_{i}, v_{i+1} \rrbracket, i=1,2,3 .
$$

Then $F l_{K}\left(X_{J}\right)$ (equipped with the intrinsic path-metric) is $\delta_{6.15}(K)$-hyperbolic.
Proof. A quick way to argue is to appeal to Corollary 2.63 since $F l_{K}\left(X_{J}\right)$ has a structure of a hyperbolic tree of spaces with the base-tree consisting of four vertices and three edges (forming an interval of length 3), where the vertex-spaces are $F l_{K}\left(X_{J_{i}}\right)$ 's and the edge-spaces are $F l_{K}\left(X_{v_{i}}\right)$ 's. We will give a more explicit proof following the proof of Corollary 2.63 since it will also provide us with a description of uniform quasigeodesics in $F l_{K}\left(X_{J}\right)$.

We will use the quasiconvex amalgamation (see Section 2.6.2) twice:
a. We have

$$
F l_{K}\left(X_{J_{1}}\right) \cap F l_{K}\left(X_{J_{2}}\right)=F l_{K}\left(X_{v_{2}}\right)
$$

The intersection is $L_{3.22}(K)$-qi embedded in $X$, hence, in $F l_{K}\left(X_{I}\right), I=J_{1} \cup J_{2}$. Since both $F l_{K}\left(X_{J_{1}}\right), F l_{K}\left(X_{J_{2}}\right)$ are $\delta_{6.14}(K)$-hyperbolic, Theorem 2.59 (for quasiconvex amalgams) implies $\epsilon_{6.15}(K)$-hyperbolicity of their union $F l_{K}\left(X_{I}\right)$.
b. We have

$$
F l_{K}\left(X_{J}\right)=F l_{K}\left(X_{I}\right) \cup F l_{K}\left(X_{J_{3}}\right),
$$

and

$$
F l_{K}\left(X_{I}\right) \cap F l_{K}\left(X_{J_{3}}\right)=F l_{K}\left(X_{v_{3}}\right) .
$$

The intersection is $L_{3.22}(K)$-qi embedded in $X$, hence, in $F l_{K}\left(X_{I}\right), I=J_{1} \cup J_{2}$. Since both $F l_{K}\left(X_{I}\right), F l_{K}\left(X_{J_{3}}\right)$ are $\delta$-hyperbolic,

$$
\delta=\max \left(\delta_{6.14}(K), \epsilon_{6.15}(K)\right)
$$

Theorem 2.59 (for quasiconvex amalgams) implies $\delta_{6.15}(K)$-hyperbolicity of their union $F l_{K}\left(X_{J}\right)$.

The following result is never used afterwards, we include the proof for the sake of completeness of the picture.

Corollary 6.16 (Hyperbolicity of the union of two flow-spaces: General case). For each $K \geq K_{0}$, for $D=D_{6.11}(K)$, assuming that $\mathfrak{X}$ satisfies the uniform $\kappa_{6.11}(K)$-flaring condition, the following holds:

If $u, v \in V(T)$ are such that $F l_{K}\left(X_{u}\right) \cap F l_{K}\left(X_{v}\right) \neq \emptyset$, then

$$
N_{D}\left(F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{v}\right)\right)
$$

is an $L_{6.16}(K)$-qi embedded, $\delta_{6.16}(K)$-hyperbolic subspace of $X$.
Proof. Since $F l_{K}\left(X_{u}\right) \cap F l_{K}\left(X_{v}\right) \neq \emptyset$, the interval $J=\llbracket u, v \rrbracket$ splits as the union of two special subintervals, $J_{1}, J_{2}$, there is a vertex $w$ in the interval $I=\llbracket u, v \rrbracket$ such that $X_{w} \cap F l_{K}\left(X_{u}\right) \neq \emptyset$ and $X_{w} \cap F l_{K}\left(X_{v}\right) \neq \emptyset$ (see Lemma 3.40). Thus, $N_{D}\left(F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{v}\right)\right.$ ) is contained in the $D$-neighborhood of the $\delta_{6.15}(K)$-hyperbolic subspace, $F l_{K}\left(X_{I}\right)$. The result now follows from Lemma 1.95 on unions of quasiconvex subsets of hyperbolic spaces, combined with Proposition 6.3.

### 6.2. Hyperbolicity of flow-spaces of general interval-spaces

This section deals with Step 3 outlined in the introduction to this chapter. Recall that according to Proposition 3.32, for every subtree $S \subset T$ and $K \geq K_{0}$, the flow-space $F l_{K}\left(X_{S}\right)$ is $L_{3.32}(K)$-qi embedded in $X$.

Theorem 6.17. For every $K \geq K_{0}$, assuming that $\mathfrak{X}$ satisfies the uniform $K_{6.11}(K)$ flaring condition, for each interval $J=\llbracket u, v \rrbracket \subset T$, the flow-space $F l_{K}\left(X_{J}\right)$ is $\delta_{6.17}(K)$ hyperbolic.

Proof. When $u=v$, the statement is established in Theorem 5.17. Therefore, we consider the case of nondegenerate intervals $J$.

We apply the Horizontal Subdivision Lemma (Lemma 3.44) and its corollary (Corollary 3.45) to subdivide the interval $J$ into subintervals $J_{0}, \ldots, J_{n}$ such that:
(i) Each $J_{i}$ is the union of three $K$-special subintervals.
(ii) Whenever $|i-j| \geq 2$, the flow-spaces $F l_{K}\left(X_{J_{i}}\right), F l_{K}\left(X_{J_{j}}\right)$ are $L_{3.21}(K)$-Lipschitz cobounded in $X$, hence (taking restrictions of Mitra's projections), in $F l_{K}\left(X_{J}\right)$ as well.

According to Corollary 6.15, each flow-space $F l_{K}\left(X_{J_{i}}\right)$ is $\delta_{6.15}(K)$-hyperbolic.
Finally, we consider the union

$$
F l_{K}\left(X_{J}\right)=\bigcup_{0 \leq i \leq n} F l_{K}\left(X_{J_{i}}\right)
$$

By Proposition 3.26(1),

$$
F l_{K}\left(X_{J_{i-1}}\right) \cap F l_{K}\left(X_{J_{i}}\right)=F l_{K}\left(X_{u_{i}}\right) .
$$

Since whenever $|i-j| \geq 2$, the flow-spaces $F l_{K}\left(X_{J_{i}}\right), F l_{K}\left(X_{J_{j}}\right)$ are $L_{3.21}(K)$-Lipschitz cobounded in $F l_{K}\left(X_{J}\right)$ and the consecutive intersections $F l_{K}\left(X_{u_{i}}\right)$ are $L_{3.21}(K)$-qi embedded in $F l_{K}\left(X_{J}\right)$, Theorem 2.59 applies and the flow-space $F l_{K}\left(X_{J}\right)$ is $\delta_{6.17}(K)$-hyperbolic.

### 6.3. Conclusion of the proof

In this section we finish the proof of the main result of this book, Theorem 2.58. We first prove that flow-spaces $F l_{K}\left(X_{S}\right)$ are uniformly hyperbolic, whenever $S$ is a tripod in $T$ (Corollary 2.63). We then conclude the proof of Theorem 2.58 by appealing to Corollary 1.64 one last time by constructing a slim combing in $X$ via geodesics in flow-spaces of interval-spaces.

Proposition 6.18. Assume that $\mathfrak{X}$ satisfies the uniform $\kappa_{6.11}(K)$-flaring condition. Suppose $S=T_{b} u_{1} u_{2} u_{3} \subset T$ is a tripod ${ }^{1}$ with the center $b$ and three extremities $u_{1}, u_{2}, u_{3}$. Then for every $K \geq K_{0}$, the flow-space $F l_{K}\left(X_{S}\right)$ is $\delta_{6.18}(K)$-hyperbolic.

Proof. The proof is similar to that of Proposition 6.15. The tripod $S$ is the union of three segments (legs) $J_{i}=\llbracket u_{i}, b \rrbracket, i=1,2,3$, whose pairwise intersections equal $\{b\}$. According to Theorem 6.17, each flow-space $F l_{K}\left(X_{J_{i}}\right)$ is $\delta_{6.17}(K)$-hyperbolic. The intersection

$$
\bigcap_{i=1}^{3} F l_{K}\left(X_{J_{i}}\right)=F l_{K}\left(X_{b}\right)
$$

(see Proposition 3.26(1)) is $\delta_{5.17}(K)$-hyperbolic (Theorem 5.17) and $L_{3.21}(K)$-qi embedded in $X$. Therefore, $F l_{K}\left(X_{S}\right)$ has structure of a tripod $\mathfrak{Y}$ ) of hyperbolic spaces

$$
Y=F l_{K}\left(X_{S}\right) \rightarrow S^{\prime}=T_{b} v_{1} v_{2} v_{3},
$$

${ }^{1}$ see Definition 1.73
where the tripod $S^{\prime}$ has four vertices $\left(b, v_{1}, v_{2}, v_{3}\right)$ and three edges, all incident to the vertex $b$. Namely, the vertex-spaces of $\mathfrak{Y}$ are $Y_{b}=F l_{K}\left(X_{b}\right), Y_{v_{i}}=F l_{K}\left(X_{J_{i}}\right)$. The three edge-spaces are all isomorphic to $Y_{b}$ and have natural incidence maps (inclusion maps) to the vertexspaces. Now, the proposition follows from Corollary 2.63.

We can now finish our proof of Theorem 2.58. We let $K=K_{0}$ and $K_{*}$ be as Notation 2.6.4 and Remark 6.12 respectively (the constants $\delta_{0}^{\prime}, \lambda_{0}^{\prime}, L_{0}^{\prime}$ used in Notation 2.6.4 are defined in Notation 2.6.4). We assume that the tree of spaces $\mathfrak{X}$ satisfies the uniform $K_{*^{-}}$ flaring condition.

We will once again apply Corollary 1.64 , with $X_{0}=\mathcal{X}$, the union of vertex-spaces in $X$. For each pair of vertices $u, v \in V(T)$, and points $x \in X_{u}, y \in X_{v}$, we define the path $c(x, y)$ in $X$ to be the intrinsic geodesic in the flow-space $Y=F l_{K}\left(X_{u v}\right)$. In order to verify the assumptions of Corollary 1.64, we observe that condition (a1) follows from the fact that each $Y$ is $L=L_{3.32}(K)$-qi embedded in $X$. We also conclude that each path $c(x, y)$ is an $L$-quasigeodesic in $X$. Condition (a2) is immediate from Proposition 6.18.

Corollary 6.19. Let $\mathfrak{X}=(\pi: X \rightarrow T)$ be a tree of hyperbolic spaces (satisfying Axiom $\mathbf{H}$ ). Then the following conditions are equivalent:

1. $X$ is hyperbolic.
2. $\mathfrak{X}$ satisfies the uniform $\kappa$-flaring condition for all $\kappa \in\left[K_{0}, K_{*}\right]$.
3. $\mathfrak{X}$ satisfies the Bestvina-Feighn exponential flaring condition for all $\kappa \geq 1$.
4. Carpets in $\mathfrak{X}$ are uniformly hyperbolic. More precisely, there exists a function $\delta(K, C)$, such that each $(K, C)$-narrow carpet in $\mathfrak{X}$ has $\delta(K, C)$-hyperbolic total space.
5. Ladders in $\mathfrak{X}$ are uniformly hyperbolic. More precisely, there exists a function $\delta(K, D, E)$, such that each $(K, D, E)$-ladder in $\mathfrak{X}$ has $\delta(K, D, E)$-hyperbolic total space.

Proof. The implication $2 \Rightarrow 1$ is the content of Theorem 2.58. The converse implication $1 \Rightarrow 2$ is Lemma 2.46. In Proposition 2.56 we proved the implication $1 \Rightarrow 3$, while the implication $3 \Rightarrow 2$ is proven in Lemma 2.55. Thus, we obtain the equivalence of 1,2 and 3.

In order to establish equivalence of 1 with 4 and 5, observe that the uniform flaring condition is defined in terms of separation properties of pairs of $K$-sections over intervals in $T$ and every such pair of sections is contained in a carpet, while each carpet is contained in a ladder. Applying the implication $1 \Rightarrow 2$ to trees of spaces which are carpets and ladders, we conclude that uniform hyperbolicity of carpets/ladders implies the uniform $\kappa$-flaring condition for $\mathfrak{X}$ for all $\kappa \geq 1$.

## CHAPTER 7

## Description of geodesics

### 7.1. Inductive description

Let $\pi: X \rightarrow T$ be a tree of hyperbolic spaces (satisfying Axiom $\mathbf{H}$ ) with hyperbolic total space $X$. We can now give a description of geodesics in $X$, more precisely, of uniform quasigeodesics. This description is inductive/hierarchical. The basis of induction is the fact that each $K$-qi leaf in $X$ (i.e. the image of a $K$-qi section of $\pi: X \rightarrow T$ over a geodesic segment in $T$ ) defines a uniform horizontal quasigeodesic in $X$. Such quasigeodesics present one type of building blocks of geodesics in $X$. The second building block consists of vertical quasigeodesics in $X$ : Such quasigeodesics are certain intrinsic geodesics in vertex-spaces $X_{v}$ of $X$. While $X_{v}$ 's (typically) are not quasiisometrically embedded in $X$, some geodesics in $X_{v}$ 's nevertheless are uniform quasigeodesics in $X$, namely, ones satisfying the small carpet condition, see Proposition 7.2 below. We will see that general geodesics in $X$ are uniformly Hausdorff-close to alternating concatenations of horizontal and vertical uniform quasigeodesics. In Section 7.3 we, furthermore, give a simpler description of uniform quasigeodesics in a more limited class of trees of spaces, namely, acylindrical trees of spaces.

There are several basic classes of subtrees of spaces in $\mathfrak{X}$, which are used in description of geodesics in $X$. All of these are special cases of semicontinuous families (of subsets of vertex-spaces) in $\mathfrak{X}$, see Chapter 3, all are uniformly quasiconvex subsets of $X$. Here is the list of these classes of subspaces, listed in order of increase of the complexity of their definitions:

- Carpets $\mathfrak{H} \subset \mathfrak{Z}$.
- Metric bundles $\mathfrak{G} \subset \mathfrak{X}$.
- Ladders $\mathfrak{L} \subset \mathfrak{X}$.
- Flow-spaces of vertex-spaces $\mathfrak{F} l_{K}\left(X_{u}\right) \subset \mathfrak{X}$.
- Flow-spaces $\mathfrak{F} l_{K}\left(X_{S}\right)$, where $S \subset T$ is a subtree and $X_{S}=\pi^{-1}(S)$.
- Flow-spaces of metric bundles $\mathfrak{F} l_{K}(\mathfrak{H}) \subset \mathfrak{X}$.

We first describe geodesics in carpets, then use those to describe geodesics in ladders, use those to describe geodesics in flow-spaces of vertex spaces. At the same time, flowspaces of metric bundles $F l_{k}(\mathfrak{H})$ are uniformly quasiconvex subsets of certain flow-spaces $F l_{K}\left(X_{u}\right)$ (form some $K \geq k$ ) and, hence, we do not give a separate description of geodesics in the former. After Step I.4, our description of geodesics in $X$ only uses geodesics in flowspaces $F l_{K}\left(X_{u}\right)$ as building blocks. A key feature of flow-spaces is that they are uniformly quasiconvex in $X$ (unlike vertex-spaces themselves). Each flow-space is itself a tree of spaces, $F l_{K}\left(X_{u}\right) \rightarrow S_{u}$, where $S_{u}$ is a subtree in $T$. The intersection pattern of the subtrees $S_{u}$ (encoded in the flow-incidence graph $\Gamma_{K}$ ) is discussed in Section 3.3.5; it will provide a guide for describing geodesics in $X$ in terms of geodesics in flow-spaces $F l_{K}\left(X_{u}\right)$.

We now describe (inductively) geodesics in $X$. Except for the two initial steps, the rest is a repetitive use of one of the following constructions:

Figure 19. Geodesics in amalgams
(a) Quasiconvex amalgams: Section 2.6.2. Given two $L$-qi embedded subsets $Q_{1}, Q_{2}$ in a $\delta$-hyperbolic space $Y$, with nonempty $L$-qi embedded intersection $Q_{12}=Q_{1} \cap Q_{2}$, the union

$$
Q=Q_{1} \cup Q_{2}
$$

is a quasiconvex amalgam of $Q_{1}, Q_{2}$.

Figure 20. Geodesics in chain-amalgams
(b) Pairwise cobounded quasiconvex chain-amalgamation. We refer to Section 2.6.2 for a detailed definition and description of uniform quasigeodesics in unions $Q=$ $Q_{0} \cup Q_{1} \cup \ldots \cup Q_{n}$ defining quasiconvex chain-amalgamation. Such amalgamations (with $n \geq 2$ ) will be used just in two instances in our proof. Briefly, paths $c$ in $Q$ are alternating concatenations of geodesics in $Q_{i, i+1}$ 's and $Q_{i}$ 's connecting points $x_{i}^{+}, x_{i+1}^{+} \in Q_{i, i+1}$ and $x_{i}^{-}, x_{i}^{+} \in Q_{i}$ where latter pairs (up to a uniformly bounded error $C$ ) realize the minimal distance between $Q_{i-1, i}, Q_{i, i+1}$ in $Q_{i}$. See Figure 20.

We now begin the inductive description of uniform quasigeodesics. Regarding constants $C, D, E, K$ appearing below: Ultimately, we will take $K=K_{*}, C=M_{\bar{K}}, D=D_{5.2}$, $E=E_{5.2}$. However, for instance, the description of paths in carpets works for all $K \geq 1$ and all $C \geq 0$, etc.

Part 0: Geodesics in $K$-qi sections of $\mathfrak{X}=(\pi: X \rightarrow T)$. The basis for the entire description of uniform quasigeodesics in $X$ is the fact that each $K$-qi leaf in $X$ is a $K$ quasigeodesic in $X$.

Part I: Geodesics in flow-spaces of vertex-spaces $F l_{K}\left(X_{\nu}\right)$.
These geodesics (or, rather, uniform quasigeodesics) are described in three steps.
Step I.1. Quasigeodesics in carpets: Section 4.1, especially, Proposition 4.1.

Figure 21. Geodesics in carpets

Let $\mathfrak{A}=(\pi: A \rightarrow J) \subset \mathfrak{X}$ be a $(K, C)$-carpet over an interval $J=\llbracket u, w \rrbracket$, such that the end $A_{w}$ of $\mathfrak{A}$ over $w$ is $C$-narrow (i.e. is a geodesic of length $\leq C$ in $X_{w}$ ).

Then for $x, y \in \mathcal{A}$ we consider $K$-sections $\gamma_{x}, \gamma_{y}$ over subintervals $\llbracket \pi(x), w \rrbracket, \llbracket \pi(y) w \rrbracket$ in $J$.

Let $t_{x y} \in \llbracket w, u \rrbracket$ denote the supremum of

$$
\left\{t \in \llbracket w, u \rrbracket: d_{X_{t}}\left(\gamma_{x}(t), \gamma_{y}(t)\right) \leq M_{K}\right\}
$$

Then an $L_{4.1}(K, C)$-quasigeodesic $c(x, y)$ in $A$ is defined as the concatenation of the section $\gamma_{x}$ restricted to $\llbracket \pi(x), t \rrbracket$ with the vertical segment $\gamma=\left[\gamma_{x}(t) \gamma_{y}(t)\right]_{X_{t}}$, followed by the concatenation with the restriction of the section $\gamma_{y}$ to the subinterval $\llbracket t, \pi(y) \rrbracket$. See figure 21.

Step I.2. Quasigeodesics in carpeted ladders with narrow carpets: Section 4.2, especially Proposition 4.6.

For a vertical geodesic segment $\alpha \subset X_{u}$, we consider a carpeted ladder, a ( $K, D, E$ )ladder $\mathfrak{L}=\mathfrak{L}_{K}(\alpha)=(\pi: A \rightarrow J)$, which contains a $(K, C)$-carpet $\mathfrak{A}=\mathfrak{A}\left(\alpha^{\prime}\right)$, where $\alpha^{\prime} \subset \alpha$ is a subsegment of length $\geq$ length $(\alpha)-M_{\bar{K}}$, where $\bar{K}$ is defined by

$$
\bar{K}:=K_{3.47}\left(\delta_{0}, K, K\right)
$$

The definition of paths $c(x, y)$ connecting points $x, y \in \mathcal{L}$ is a 2 -part process.

Part a: Retraction $\rho$ and paths $c_{x}$. In Section 3.4 we defined a retraction $\rho: L_{K}(\alpha) \rightarrow$ $A$ : This retraction is uniformly close to the nearest-point projection, see Remark 3.64. This retraction plays critical role in the definition of our combing of $L_{K}(\alpha)$. Below is a review of the definition of the retraction in terms of the structure of the tree of spaces.

For a point $x \in \mathcal{L}_{v}$, let $\gamma_{x}$ be a canonical $K$-leaf in $\mathcal{L}$ connecting $x$ to $\alpha$ : Such leaves are a part of the definition of a ladder. Ultimately, which leaf one takes does not matter and the paths $c_{x}$ change only uniformly bounded amount if one makes a different choice. Let $t=t_{x} \in \llbracket u, v \rrbracket$ be the vertex farthest from $u$ such that $\pi(x) \in J$ and there exists a point $\tilde{x} \in \gamma_{x}(t)$ for which

$$
d_{X_{t}}\left(\tilde{x}, A_{t}\right) \leq M_{\bar{K}}
$$

(It is possible that $t=u$ and $\tilde{x} \in A_{u}=\alpha$.) Then define a path $c_{x}$ connecting $x$ to $\rho(x)=\bar{x}$ and equal to the concatenation

$$
\gamma_{x, \tilde{x}} \star[\tilde{x} \bar{x}]_{X_{t}} .
$$

Here $t=t_{x}$, and

$$
\gamma_{x, \tilde{x}}=\gamma_{x} \|_{\llbracket v, t \rrbracket}
$$

is the subpath of $\gamma_{x}$ connecting $x$ to $\tilde{x}$, while $\bar{x} \in A_{t}$ is a nearest-point projection of $\tilde{x}$ to $A_{t}$ in the vertex-space $X_{t}$. Since $c_{x}$ is uniformly Hausdorff-close to $\gamma_{x, \tilde{x}}$, the point $\rho(x)$ essentially determines the path $c_{x}$.

Figure 22. Geodesics in ladders: Type 1
Part b: Paths $c(x, y)$. For $x, y \in \mathcal{L}$ we let $b=b_{x y}$ be the center of the triangle $\Delta u \pi(x) \pi(y)$. The path $c(x, y)$ in $L_{K}(\alpha)$ connecting $x$ to $y$ is defined as follows.

Paths of type 1: There exists $t \in V(\llbracket \pi(x), \pi(\bar{x}) \rrbracket \cap \llbracket \pi(y), \pi(\bar{y}) \rrbracket) \subset V(\llbracket u, b \rrbracket)$ such that

$$
d_{X_{t}}\left(\gamma_{x}(t), \gamma_{y}(t)\right) \leq M_{\bar{K}},
$$

i.e. the paths $\gamma_{x}, \gamma_{y}$ "come sufficiently close" in some common vertex-space.

Then let $t=t_{x, y}$ be the maximal vertex in $\llbracket u, b \rrbracket$ with this property. Then define $c(x, y)$ to be the concatenation of the portions of $\gamma_{x}$ and (the reverse of) $\gamma_{y}$ over $\llbracket t, \pi(x) \rrbracket$ and $\llbracket t, \pi(y) \rrbracket$ respectively with the subsegment $\gamma \subset L_{t}$ joining their end-points. See Figure 22.

Paths of type 2: Suppose type 1 does not happen. Then define $c(x, y)$ to be the concatenation of $c_{x}$ and the reverse of $c_{y}$ with a geodesic in $A$ connecting $\rho(x)$ to $\rho(y)$. See Figure 23.

Remark 7.1. The geodesic in $A$ here is taken for granted, see Step I.1. In fact, instead of a geodesic one should take a path $c(\rho(x), \rho(y))$ in $A$ defined in Step I.1. Such inductive arguments will be common in what follows and we will simply say "geodesic."

Figure 23. Geodesics in ladders: Type 2
One more thing of importance is that the vertical segments

$$
[\tilde{x} \rho(x)]_{X_{u_{x}}}, \quad\left[\rho(y) \tilde{y} \tilde{X}_{u_{u_{y}}}\right.
$$

have length $\leq M_{\bar{K}}$, hence, for paths of both types we are essentially concatenating at most three paths, two of which are horizontal subpaths of $c_{x}, c_{y}$ and one which lies in the carpet $A$. (The latter is also essentially a concatenation of two horizontal paths.)

Step I.3. Quasigeodesics in general $(K, D, E)$-ladders $\mathbb{L}(\alpha)$ : Section 4.3, especially Proposition 4.11.

In this case, uniform quasigeodesics are constructed via cobounded quasiconvex amalgamation, amalgamating ladders $\mathfrak{L}_{K}\left(\alpha_{1}\right), \ldots, \mathfrak{L}_{K}\left(\alpha_{n+1}\right)$ along uniformly pairwise cobounded uniformly quasiconvex subsets $\Sigma_{1}=\Sigma_{p_{1}}, \ldots, \Sigma_{n-1}=\Sigma_{p_{n-1}}$, which are canonical $K$-qi sections of these ladders.

We consider a ladder $\mathfrak{L}=\mathfrak{L}_{K}(\alpha)$ of a vertical geodesic $\alpha=[p q]_{X_{u}}$ and a pair of points $x, x^{\prime} \in L_{K}(\alpha)$, connected to the end-points $p, p^{\prime}$ of $\alpha$ by $K$-qi leaves in $L_{K}(\alpha)$.

In Proposition 4.11 we prove the existence of a Vertical Subdivision of every vertical geodesic segment $\alpha \subset X_{u}, \alpha=\left[p p^{\prime}\right]_{X_{u}}$ into subsegments

$$
\alpha_{1}=\left[p_{1} p_{2}\right]_{X_{u}}, \ldots, \alpha_{n}=\left[p_{n} p_{n+1}\right]_{X_{u}}, p_{1}=p, p_{n+1}=p^{\prime}
$$

such that:
(a) For each $i$, the segment $\alpha_{i}$ defines a carpeted ladder $\mathfrak{L}^{i}=\mathfrak{L}_{K}\left(\alpha_{i}\right)$ which is a $(K, D, E)$-subladder in $\mathfrak{L}$ containing a $(K, C)$-narrow carpet $\mathfrak{A}_{K}\left(\alpha_{i}^{\prime}\right)\left(\right.$ for $\left.C=M_{\bar{K}}\right)$.
(b) The canonical sections $\Sigma_{i}, \Sigma_{i+1}($ in $\mathfrak{L})$ through the points $p_{i}, p_{i+1}$ are, respectively, the bottom and the top sections of $\mathfrak{\Sigma}^{i}$, so that

$$
L^{i-1} \cap L^{i}=\Sigma_{i}
$$

(c) The sections $\Sigma_{i}, \Sigma_{i+1}$ are $B_{4.11}(K, C)$-cobounded unless $i=n$.
(d) For all $i$,

$$
0 \leq l_{i}-\text { length }\left(\alpha_{i}^{\prime}\right) \leq M_{K} \leq M_{\bar{K}} .
$$

(e) The top and bottom sections $\Sigma_{p}, \Sigma_{p^{\prime}}$ of $\mathfrak{Q}$ pass through the points $x, x^{\prime}$.

In particular, the ladder $L$ is a quasiconvex amalgam of its subladders $L^{i}$ with pairwise intersections $L^{i-1} \cap L^{i}=\Sigma_{i}$.

Figure 24. Geodesics in general ladders: Vertical subdivision

As a part of the proof of the Vertical Subdivision Proposition (Proposition 4.11), we identify (up to a uniformly bounded error) the nearest points $x_{i}^{-} \in \Sigma_{i}, x_{i}^{+} \in \Sigma_{i+1}$ between these cobounded subsets. Namely, by the construction, the ladder $\mathbb{Q}^{i}$ contains the carpet $\mathfrak{A}\left(\alpha_{i}^{\prime}\right)$ over an interval $\llbracket u, w_{i} \rrbracket$, with the narrow end

$$
A_{w_{i}}=\left[x_{w_{i}} y_{w_{i}}\right]_{x_{w_{i}}} .
$$

Then (up to a uniformly bounded error),

$$
x_{i}^{-}=x_{w_{i}}
$$

The description of the point $x_{i}^{+}$is more complicated, see Lemma 4.12.
The paths $c\left(x_{i}^{-}, x_{i}^{+}\right)$are defined according to Step I. 2 and the paths $c\left(x_{i}^{+}, x_{i+1}^{-}\right)$are defined as in Part 0 (by using $K$-qi leaves in the $K$-qi section $\Sigma_{i}$ ). Lastly, according to Theorem 2.59,

$$
c\left(x, x^{\prime}\right)=c\left(x, x_{1}^{+}\right) \star c\left(x_{1}^{+}, x_{2}^{-}\right) \star \ldots \star c\left(x_{n}^{-}, x_{n}^{+}\right) \star c\left(x_{n}^{+}, x^{\prime}\right)
$$

where $c\left(x, x_{1}^{+}\right), c\left(x_{n}^{+}, x^{\prime}\right)$ are the uniformly quasigeodesic paths in carpeted ladders $\mathfrak{R}^{1}$ and $\mathfrak{L}^{n}$ respectively as defined in Step I.2.

Conclusion of Part I: Quasigeodesics in flow-spaces $F l_{k}\left(X_{u}\right)$ of vertex-spaces. Any two points $x, x^{\prime} \in F l_{k}\left(X_{u}\right)$ belong to a common $(K, D, E)$-ladder $\mathfrak{R}_{x, x^{\prime}}=\mathfrak{L}(\alpha)$, where $\alpha$ is a certain geodesic in $X_{u}$ and $K, D, E$ depend on $k$. The ladder itself is uniformly close to a uniformly quasiconvex subset of $F l_{k}\left(X_{u}\right)$. Hence, Step I. 3 yields a description of uniform quasigeodesics $c\left(x, x^{\prime}\right)$ connecting arbitrary points $x, x^{\prime} \in F l_{k}\left(X_{u}\right)$ (the path $c\left(x, x^{\prime}\right)$ is the projection to $F l_{k}\left(X_{u}\right)$ of a geodesic in $L(\alpha)$ connecting $\left.x, x^{\prime}\right)$.

Part II: Connecting points in flow-spaces $F l_{k}\left(X_{J}\right)$ for special intervals $J \subset T$. An interval $J=\llbracket u, v \rrbracket \subset T$ is said to be special (more precisely, $k$-special) if some $w \in\{u, v\}$ has the property that $J \subset \pi\left(F l_{k}\left(X_{w}\right)\right)$; such $w$ is called a special vertex in $J$. The flowspace $F l_{k}\left(X_{J}\right)$ then is called a special flow-space (more precisely, $k$-special flow-space). Similarly, an interval $J \subset T$ is $k$-semispecial if it is the union of two special intervals meeting at a vertex. Accordingly, for such $J$, the flow-space $F l_{k}\left(X_{J}\right)$ is $k$-semispecial. Uniform quasigeodesics in $F l_{k}\left(X_{J}\right)$ in this setting are described using pairwise quasiconvex amalgams of hyperbolic spaces.

## Step II.4. Uniform quasigeodesics in special flow-spaces: Section 6.1.2, especially

 Proposition 6.10, Corollary 6.11.We assume that $J=\llbracket u, v \rrbracket \subset T$ is a $K$-special interval in $T$. The flow-spaces $F l_{K}\left(X_{u}\right)$, $F l_{K}\left(X_{v}\right)$ are uniformly quasiconvex in $X$, hence, a uniform $D$-neighborhood of this union in $X$ is hyperbolic. The constant $D$ is defined in Corollary 6.11. On this step, we describe uniform quasigeodesics in $X$ connecting points of $F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{v}\right)$ and uniformly close to such a union.

We first define a certain metric bundle $\mathfrak{H}$ over $J$. We then combine the generalized flow-space $Y_{0}=F l_{R}(\mathfrak{H})$ of this bundle (for some $R=R(K)$ ) with the flow-spaces $F l_{K}\left(X_{u}\right)$, $F l_{K}\left(X_{\nu}\right)$ to get "modified flow-spaces" $Y_{1}=F l_{K}\left(X_{u}\right) \cup F l_{R}(\mathfrak{H}), Y_{2}=F l_{K}\left(X_{\nu}\right) \cup F l_{R}(\mathfrak{H})$. The union

$$
U=U_{1} \cup U_{2}=N_{D}\left(Y_{1}\right) \cup N_{D}\left(Y_{2}\right)
$$

is uniformly qi embedded in $X$, while the intersection $U_{1} \cap U_{2}$ is uniformly quasiconvex and uniformly Hausdorff-close to $Y_{0}$. Moreover, $U_{1}, U_{2}$ are uniformly Hausdorff-close to subsets in $Z_{1}=F l_{K_{1}}\left(Y_{1}\right), Z_{2}=F l_{K_{1}}\left(Y_{2}\right)$ for some (computable $K_{1} \geq K$ ).

Hence, we are in the setting of the quasiconvex amalgamation of a pair (Section 2.6.2). To connect $x \in F l_{K}\left(X_{u}\right), y \in F l_{K}\left(X_{v}\right)$ by a uniform quasigeodesic uniformly close to $F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{v}\right)$ we proceed as in Section 2.6.2:

We first project (in $F l_{K_{1}}\left(Y_{1}\right), F l_{K_{1}}\left(Y_{2}\right)$ respectively) the points $x, y$ to points $\bar{x}, \bar{y} \in$ $Y_{0}=F l_{K}(\mathfrak{H})$ (one can also use projections in $U$ or in $X$, the difference will be uniformly bounded) and then connect $\bar{x}, \bar{y}$ in $Y_{0}$. The concatenations

$$
[x \bar{x}]_{Z_{1}} \star[\bar{x} \bar{y}]_{Y_{0}} \star[\bar{y} y]_{Z_{2}}
$$

are uniform quasigeodesics in $X$ and are uniformly close to $F l_{K}\left(X_{u}\right) \cup F l_{K}\left(X_{v}\right)$.
Step II.5: Uniform quasigeodesics in semispecial flow-spaces: Proposition 6.13 and Theorem 6.14.

Suppose now a semispecial interval $S=\llbracket u, v \rrbracket=I \cup J$, where both $I=\llbracket u, w \rrbracket, J=$ $\llbracket w, v \rrbracket$ are special intervals. Then for $s \in V(I)$ and $t \in V(J)$, uniform quasigeodesics in $F l_{K}\left(X_{S}\right)$ connecting points $x \in F l_{K}(\llbracket s, w \rrbracket), y \in F l_{K}(\llbracket w, t \rrbracket)$ are described as follows. The union

$$
F l_{K}(\llbracket s, w \rrbracket) \cup F l_{K}(\llbracket w, t \rrbracket)
$$

is a quasiconvex amalgam over the flow-space $F l_{K}\left(X_{w}\right)$. Therefore, according to the description of uniform quasigeodesics in quasiconvex amalgams, we first project (using nearest-point projections in $Z_{1}=N_{D}\left(F l_{K}\left(X_{s}\right) \cup F l_{K}\left(X_{w}\right)\right)$, resp. in $Z_{2}=N_{D}\left(F l_{K}\left(X_{t}\right) \cup\right.$ $F l_{K}\left(X_{w}\right)$ )) points $x$ (resp. $y$ ) to $\bar{x} \in F l_{K}\left(X_{w}\right)$ (resp. $\bar{y} \in F l_{K}\left(X_{w}\right)$ ), and then take the concatenation

$$
[x \bar{x}]_{Z_{1}} \star[\bar{x} \bar{y}]_{F l_{K}\left(X_{w}\right)} \star[\bar{y} y]_{Z_{2}} .
$$

The first and the last geodesics in this concatenation are from Step II.4, while the middle one is from the conclusion of Part I.

Step II.6: Uniform quasigeodesics in triple unions of special flow-spaces: Corollary 6.15.

Suppose that $J$ is an interval in $T$, that can be subdivided as a union of three special subintervals, $J=J_{1} \cup J_{2} \cup J_{3}$,

$$
J_{i}=\llbracket v_{i}, v_{i+1} \rrbracket, i=1,2,3 .
$$

Set $I:=J_{1} \cup J_{2}$. Then geodesics in $F l_{K}\left(X_{J}\right)$ are described by applying quasiconvex amalgamation of pairs twice: Once to

$$
F l_{K}\left(X_{I}\right)=F l_{K}\left(X_{J_{1} \cup J_{2}}\right)
$$

which is the amalgam of $F l_{K}\left(J_{1}\right), F l_{K}\left(J_{2}\right)$ over $F l_{K}\left(X_{v_{2}}\right)$, and then once more, to

$$
F l_{K}\left(X_{I \cup J_{3}}\right)
$$

which is the amalgam of $F l_{K}(I), F l_{K}\left(J_{3}\right)$ over $F l_{K}\left(X_{v_{3}}\right)$.

## Part III: Connecting general points in $X$.

## Step III.7: Horizontal subdivision.

Any two points $x, y \in \mathcal{X}$ belong to the interval flow-space $F l_{K}\left(X_{J}\right)$, where $J=\llbracket u, v \rrbracket \subset$ $T, x \in X_{u}, y \in X_{v}$. Since the flow-space $F l_{K}\left(X_{J}\right)$ is (uniformly) quasiconvex in $X$, it suffices to describe a uniform quasigeodesic in $F l_{K}\left(X_{J}\right)$ connecting $x$ to $y$. The key ingredient of this part is the Horizontal Subdivision Lemma (Lemma 3.44). This lemma gives a subdivision of the interval $J$ into subintervals $J_{i}=\llbracket u_{i}, u_{i+1} \rrbracket, i=1, \ldots, n$, such that:

1. $F l_{K}\left(J_{i}\right) \cap F l_{K}\left(J_{j}\right)=\emptyset$ whenever $|i-j| \geq 2$.
2. Each interval $J_{i}$ is subdivided in three special subintervals.

This represents $F l_{K}\left(X_{J}\right)$ as a (uniformly) pairwise cobounded quasiconvex chain with quasiconvex subsets $Q_{i}=F l_{K}\left(X_{J_{i}}\right), i=1, \ldots, n$, whose consecutive intersections

$$
Q_{i-1} \cap Q_{i}=Q_{i-1, i}=F l_{K}\left(X_{u_{i}}\right)
$$

separate in the union $F l_{K}\left(X_{J}\right)$ as required by a cobounded quasiconvex chain-amalgamation. Thus, uniform quasigeodesics in $F l_{K}\left(X_{J}\right)$ are described according to Section 2.6.2, see the discussion of quasiconvex chain-amalgamation given early in this section.

This concludes our description of uniform quasigeodesics between points of $X$.

### 7.2. Characterization of vertical quasigeodesics

In this section we use the description of uniform quasigeodesics in $X$ to characterize vertical geodesics in $X$ (i.e. geodesics in vertex-spaces $X_{u}$ ) which are quasigeodesics in $X$. We assume that $\mathfrak{X}=(\pi: X \rightarrow T)$ is a tree of spaces satisfying the assumptions of Theorem 2.58, equivalently, a tree of hyperbolic spaces with hyperbolic total space $X$. Set $K=K_{0}$ and let $C=M_{\bar{K}}, D=D_{5.2}, E=E_{5.2}$.

Suppose that $\alpha$ is (finite or infinite) geodesic in $X_{u}$. We will say that $\alpha$ satisfies the $R$-small carpet condition if whenever $\alpha^{\prime} \subset \alpha$ is a subsegment which bounds a ( $K, C$ )narrow carpet $\mathfrak{A}=\mathfrak{A}\left(\alpha^{\prime}\right) \subset \mathfrak{X}, \mathfrak{A}=(\pi: A \rightarrow \llbracket u, w \rrbracket)$, with fiberwise distances between top $(\mathfrak{A l}), \operatorname{bot}(\mathfrak{H})$ at least $M_{K}$, then we have

$$
d_{T}(u, w)=\text { length } \pi(A) \leq R .
$$

In view of Corollary 2.38, for such $\alpha$ 's, the lengths of subsegments $\alpha^{\prime} \subset \alpha$ bounding ( $K, C$ )-narrow carpets $\mathfrak{A}\left(\alpha^{\prime}\right)$, are uniformly bounded.

The main result of this section is that a vertical geodesic $\alpha$ satisfies the small carpet condition if and only if it is quasigeodesic in $X$. More precisely:

Proposition 7.2. 1. Each vertical geodesic $\alpha$ satisfying the $R$-small carpet condition is an $L_{7.2}(R)$-quasigeodesic in $X$.
2. If $\alpha$ fails the $R$-small carpet condition for all $R$, then $\alpha$ is not a quasigeodesic in $X$.

Proof. 1. Let $\mathfrak{L}=\mathfrak{L}_{K}(\alpha)$ denote a $(K, D, E)$-ladder in $X$ based on the segment $\alpha$. Since $L_{K}(\alpha)$ is uniformly qi embedded in $X$ (see Corollary 3.13), it suffices to show that $\alpha$ is a uniform quasigeodesic in $L_{K}(\alpha)$. We follow the description of uniform quasigeodesics geodesics in $L_{K}(\alpha)$ given in Step I. 3 in the previous section. We subdivide the segment $\alpha=\left[p p^{\prime}\right]_{X_{v}}=\left[p_{1} p_{n+1}\right]_{X_{u}}$ into subsegments

$$
\alpha_{i}=\left[p_{i} p_{i+1}\right]_{X_{u}}, i=1, \ldots, n
$$

Each $\alpha_{i}$ (except for possibly $i=n$ ) contains a subsegment $\alpha_{i}^{\prime}$ such that

$$
M_{K} \leq \operatorname{length}\left(\alpha_{i}\right)-M_{K} \leq \operatorname{length}\left(\alpha_{i}^{\prime}\right)
$$

and there exists a $(K, C)$-carpet $\mathfrak{A}^{i}=\mathfrak{A}_{(K, C)}\left(\alpha_{i}\right) \subset \mathfrak{Z}$; the bottom and the top of $\mathfrak{Q}^{i}$ are $K$-qi sections $\Sigma_{i}, \Sigma_{i+1} \subset \mathfrak{Q}^{i}$ of a subladder $\mathfrak{L}^{i} \subset \mathfrak{L}$. Moreover, for each vertex $t$ in the interval $\pi\left(A^{i}\right)$,

$$
d_{X_{t}}\left(\operatorname{top}\left(A^{i}\right)_{t}, \operatorname{bot}\left(A^{i}\right)_{t}\right) \geq M_{K}
$$

For each $i$ we mark the points $x_{i}^{-} \in \Sigma_{i}, x_{i}^{+} \in \Sigma_{i+1}$ which (up to a uniformly bounded error) are the nearest points in $L^{i}$ between these subsets and consider geodesics

$$
\begin{gathered}
\beta_{i}=\left[x_{i}^{-} x_{i}^{+}\right]_{L^{L}}, \\
\gamma_{i}^{-}:=\gamma_{x_{i-1}^{+}, x_{i}^{-}}=\left[x_{i-1}^{+} x_{i}^{-}\right]_{\Sigma_{i}} \subset \Sigma_{i}, \\
\gamma_{i}^{+}:=\gamma_{x_{i}^{+}, x_{i+1}^{-}}=\left[x_{i}^{+} x_{i+1}^{-}\right]_{\Sigma_{i+1}} \subset \Sigma_{i+1} .
\end{gathered}
$$

The path $c\left(p, p^{\prime}\right)$ then is (up to a uniformly bounded error) equal the concatenation

$$
c=\ldots \star \gamma_{i}^{-} \star \beta_{i} \star \gamma_{i}^{+} \star \ldots
$$

Our goal is to show that the path $c$ is uniformly Hausdorff-close to $\alpha$. Because the lengths of projections $\pi\left(A_{i}\right)$ are uniformly bounded, the geodesics $\beta_{i}$ are uniformly close to the vertical geodesics $\alpha_{i}$. For the same reason, the paths $\gamma_{i}^{ \pm}$are uniformly short as well. Hence, each concatenation

$$
\gamma_{i}^{-} \star \beta_{i} \star \gamma_{i}^{+}
$$

is $r=r_{7.2}(R)$-Hausdorff close to the vertical geodesic segment $\alpha_{i}$. It follows that $\operatorname{Hd}(\alpha, c) \leq$ $r$ as well. Now, the first statement of the proposition follows from Lemma 1.20.
2. Suppose that $\alpha$ contains a sequence of subsegments $\alpha_{i}$ each bounding a ( $K, C$ )carpet $\mathfrak{A}^{i}=\mathfrak{A}_{(K, C)}\left(\alpha_{i}\right)=\left(\pi: A^{i} \rightarrow J_{i}=\llbracket u, w_{i} \rrbracket\right)$, such that

$$
\lim _{i \rightarrow \infty} d_{T}\left(u, w_{i}\right)=\infty
$$

and for each vertex $t$ in the interval $J_{i}$,

$$
d_{X_{t}}\left(\operatorname{top}\left(A^{i}\right)_{t}, \operatorname{bot}\left(A^{i}\right)_{t}\right) \geq M_{K}
$$

Therefore, the concatenation $c_{i}$ of the bottom of $\mathfrak{A}^{i}$, the narrow end $\beta_{i}$ and the top of $\mathfrak{A}^{i}$ is an $L_{4.1}(K, C)$-quasigeodesic in $A^{i}$. Since

$$
d\left(\alpha_{i}, \beta_{i}\right) \geq d_{T}\left(u, w_{i}\right)
$$

the Hausdorff distances between $\alpha_{i}$ and $c_{i}$ diverge to infinity. Morse lemma and hyperbolicity of $X$ then imply that $\alpha_{i}$ 's cannot be uniform quasigeodesics in $X$. Therefore, $\alpha$ is not a quasigeodesic in $X$ either.

### 7.3. Visual boundary and geodesics in acylindrical trees of spaces

In this section we specialize our discussion of geodesics in trees of hyperbolic spaces to the case of $(M, K, \tau)$-acylindrical trees of hyperbolic spaces satisfying Axiom $\mathbf{H}$, see Definition 2.50 ; the constant $K$ will be taken equal $K=K_{*}=K_{2.58}\left(\delta_{0}, L_{0}\right)$ although, many arguments will go through for smaller values of $K$. Besides uniform quasigeodesics we will also describe the ideal boundary of $X$. In the group-theoretic setting, when $X$ is the Cayley graph of the fundamental group of an acylindrical graph of hyperbolic groups with quasiconvex edge-subgroups, such description of the boundary is due to Dahmani, [Dah03] (who also gave a description in the relatively hyperbolic case).

Lemma 7.3. Suppose $\pi: X \rightarrow T$ is a $(M, K, \tau)$-acylindrical tree of hyperbolic spaces satisfying Axiom $\mathbf{H}$ for some $M$ and $\tau$. Then (1) $X$ is hyperbolic. (2) For subtrees $S \subset T$, the subspaces $X_{S}$ are uniformly qi embedded in $X$.

Proof. (1) Recall (Section 2.5.2), that ( $M, K, \tau$ )-acylindricity implies uniform $K$-flaring, hence, by Theorem 2.58 , hyperbolicity of $X$.
(2) Let $v \in V(T)$. Then, by Proposition 7.2, every geodesic in $X_{v}$ is a uniform quasigeodesic in $X$. Thus $X_{v}$ is uniformly qi embedded in $X$. Consequently $X_{v}$ is uniformly quasiconvex too. Then it follows that $X_{S}$ is also uniformly quasiconvex in $X$ for the following reason. Suppose a geodesic segment $\beta$ of $X$ joining a pair of points in $X_{S}$ is not entirely contained in $X_{S}$. Then the closure $\beta_{w}$ of each connected component of $\beta \backslash X_{S}$ joins two points of $X_{w}$ for some $w \in S$. Since vertex-spaces $X_{w}$ are uniformly quasiconvex in $X$, the geodesic $\beta_{w}$ is uniformly close to $X_{w}$. It follows that the entire $\beta$ is uniformly close to $X_{S}$.

Finally we know that $X_{S}$ is uniformly properly embedded in $X$ by Proposition 2.17. Hence, $X_{S}$ is uniformly qi embedded in $X$ by Lemma 1.99 and Lemma 1.15.

Description of quasigeodesics. Suppose that $\mathfrak{X}$ is $(M, K, \tau)$-acylindrical, $x \in X_{u}, y \in$ $X_{v}, u, v \in V(T)$. Without loss of generality, $\tau \in \mathbb{N}$. Since, by the above lemma, $X_{\llbracket u, v \rrbracket}$ is uniformly qi embedded in $X$, it suffices to describe uniform quasigeodesics connecting $x, y$ in $X_{\llbracket u, v \rrbracket}$. Hence, from now on, we will assume that the tree $T$ is an interval $\llbracket u, v \rrbracket$. Let

$$
t_{0}=u, t_{1}, \ldots, t_{m}=v
$$

denote the consecutive vertices in the interval $\llbracket u, v \rrbracket$. Define $A_{i-1}:=X_{e_{i} t_{i-1}}=f_{e_{i} t_{i-1}}\left(X_{e_{i}}\right) \subset$ $X_{i-1}$ and $B_{i}:=X_{e_{i} t_{i}}=f_{e_{i} t_{i}}\left(X_{e_{i}}\right) \subset X_{t_{i}}$ for $1 \leq i \leq m-1$. We inductively construct points $x_{i}^{+}, x_{i}^{-} \in X_{t_{i}}$ for $0 \leq i \leq m$ as follows.

Set $x_{0}^{-}=x$ and $x_{0}^{+}=P_{X_{t_{0}}, A_{0}}(x)$. Now, suppose that $x_{i}^{+}, x_{i}^{-} \in X_{t_{i}}$ are already defined for some $i<m$. Then we define $x_{i+1}^{-}$to be an arbitrary point of $f_{e_{i+1} t_{i+1}}\left(f_{e_{i+1}, t_{i}}^{-1}\left(x_{i}^{+}\right)\right)$and $x_{i+1}^{+}:=P_{X_{i+1}, A_{i+1}}\left(x_{i+1}^{-}\right)$. We define $x_{m}^{+}:=y$.

Lastly, we define the path $\gamma(x, y)$ as the concatenation of the segments $\left[x_{i}^{-} x_{i}^{+}\right]_{X_{t_{i}}}$ for $0 \leq i \leq m$, and unit segments in $X_{t_{i t i+1}}$ joining each pair $x_{i}^{+}, x_{i+1}^{-}$for $0 \leq i \leq m-1$.

Proposition 7.4. The path $\gamma(x, y)$ is a uniform quasigeodesic in $X$ joining $x, y$. Moreover, $x_{m}^{-}$is uniformly close to the nearest point projection of $x$ to $X_{v}$.

Proof. The proof is based on several lemmata. We first prove the claim for constants depending on $m$ and then eliminate this dependence.

Lemma 7.5. 1. The path $\gamma(x, y)$ is an $L_{7.5}(m)$-quasigeodesic.
2. The distance between $x_{m}^{-}$and the projection of $x$ to $X_{t_{m}}$ inside $X_{\llbracket u, v \rrbracket}$ is bounded by $D_{7.5}(\mathrm{~m})$.

Proof. In view of uniform quasiconvexity in $X=X_{\llbracket u, v \rrbracket}$ of vertex-spaces and of subintervals of spaces $X_{\llbracket t_{i}, t_{j} \rrbracket}$, the statements follow from, respectively, Parts 1 and 2 of Lemma 1.109 .

Below we set $R=R_{1.120}\left(\delta_{0}, \lambda_{0}\right)=\lambda_{0}+5 \delta_{0}$ and note that $K \geq R+1$.
Lemma 7.6. Each pair of vertex spaces $X_{u}, X_{v}$ satisfying $d_{T}(v, w)=m \geq \tau$, is $C_{7.6}(m)$ cobounded in $X$.

Proof. We start with a pair of points $x, z \in X_{u}$ and inductively project them to points $x_{i}^{-}, z_{i}^{-} \in X_{i}, 1 \leq i \leq m$, using the notation above.

According to Lemma $1.120(1)$, for each $i$ one of two things happens, where $\delta_{0}$ is the hyperbolicity constant of $X_{t_{i}}$ and $\lambda_{0}$ is the quasiconvexity constant of $A_{i}$ in $X_{t_{i}}$ :
(a) $d_{X_{t_{i}}}\left(x_{i}^{+}, z_{i}^{+}\right) \leq D_{1.120}\left(\delta_{0}, \lambda_{0}\right)=2 \lambda_{0}+7 \delta_{0}$.
(b) $\left[x_{i}^{+} z_{i}^{+}\right]_{X_{t i}} \subset N_{R}\left(\left[x_{i}^{-} z_{i}^{-}\right]_{X_{t}}\right)$, where, as above, $R=R_{1.120}\left(\delta_{0}, \lambda_{0}\right)=\lambda_{0}+5 \delta_{0}$.

If (a) occurs for some $i$, then the distance between $x_{i}^{-}, z_{i}^{-} \in X_{t_{i}}$ is uniformly bounded; hence, the distance between $x_{m}^{-}, z_{m}^{-} \in X_{t_{m}}=X_{v}$ is uniformly bounded as well, with bound depending on $m$. Suppose, therefore, that (b) holds for every $i$. Then for $k=R+1$, there exists a pair of $k$-sections $\gamma_{0}, \gamma_{1}$ over $\llbracket u, v \rrbracket$ such that

$$
\gamma_{0}\left(t_{i}\right)=x_{i}^{-}, \quad \gamma_{1}\left(t_{i}\right)=z_{i}^{-}, i=0, \ldots, m .
$$

Since, by the assumption, $K \geq k$, the acylindricity condition implies that $d_{X_{v}}\left(x_{m}^{-}, z_{m}^{-}\right) \leq M$. Combining this with Lemma 7.5(2), we obtain a uniform (in terms of $m$ ) bound on the distance between the projections of $x, z$ to $X_{v}$.

We are now ready to prove the proposition. We let $N:=\left\lfloor\frac{m}{\tau}\right\rfloor$ and define the subintervals

$$
J_{i}=\llbracket v_{i}, v_{i+1} \rrbracket, v_{i}=t_{i \tau}, i=0, \ldots, N,
$$

in $\llbracket u, v \rrbracket$. These subintervals cover $\llbracket u, v \rrbracket$ except for the subinterval $J_{N+1}=\llbracket v_{N+1}, v \rrbracket$ whose length is $<\tau$. Set

$$
x_{i}:=x_{i \tau}^{-}, i=0, \ldots, N
$$

Since the subspaces $X_{J_{i}}$ are uniformly quasiconvex in $X$ and each pair $X_{J_{i-1}}, X_{J_{i+1}}$ is uniformly cobounded, it follows from Theorem 2.59 on quasiconvex chain-amalgams that the concatenation

$$
\left[x_{0} x_{1}\right] \star \ldots \star\left[x_{N} x_{N+1}\right] \star\left[x_{N+1} y\right]
$$

is a uniform quasigeodesic in $X$. Furthermore, by Lemma 7.5(1), each path

$$
\gamma\left(x_{i}, x_{i+1}\right), i=0, \ldots, N, \gamma\left(x_{N}, y\right),
$$

is also a uniform quasigeodesic. Thus, the entire path $\gamma(x, y)$ is uniformly quasigeodesic as well.

Definition 7.7. We shall refer to the (uniform) quasigeodesics of the type described in Proposition 7.4 as HV (horizontal-vertical) quasigeodesics in what follows.

Up to a uniform error, these HV quasigeodesics describe all finite geodesics in $X$. Our next goal is to extend this description to the rays in $X$. We will do so under the extra assumption that $X$ is a proper metric space. Of course, as before, we also suppose that $\pi: X \rightarrow T$ is a $(M, K, \tau)$-acylindrical tree of hyperbolic spaces satisfying Axiom $\mathbf{H}$.

Fix $v_{0} \in V(T)$ and $x_{0} \in X_{v_{0}}$. We will describe (quasi)geodesic rays in $X$ starting from $x_{0}$. First of all, for every $v \in V(T)$ we fix once and for all an HV uniform quasigeodesic $\gamma_{v}$ joining to $x_{0}$ to a point $x_{v} \in X_{v}$ where:
(1) $x_{v}$ is uniformly close to a nearest point projection of $x_{0}$ to $X_{v}$ as we obtained in Proposition 7.4;
(2) for each $w \in \llbracket v_{0}, v \rrbracket$ we have $\gamma_{w} \subset \gamma_{v}$.

One defines $\gamma_{v}$ by induction on $d\left(v_{0}, v\right)$. Note that for each vertex $w \in \llbracket v_{0}, v \rrbracket$, the preimage of $w$ in $\gamma_{v}$ under the projection $\pi$ is an interval. In this situation, we will say that $\gamma_{v}$ projects monotonically to $\llbracket v_{0}, v \rrbracket$.

Armed with this, we can now describe quasigeodesic rays in $X$.
Rays of type 1: Let $v \in V(T)$ and $\xi_{v} \in \partial_{\infty} X_{v}$. Let $\alpha_{v}$ be a geodesic ray in $X_{v}$ joining $x_{v}$ to $\xi_{v}$. Then $\rho_{v}:=\gamma_{v} \star \alpha_{v}$ is a uniform quasigeodesic in $X$ by Proposition 7.4.

Rays of type 2: On the other hand, suppose that $c=v_{0} \eta$ is a geodesic ray in $T$ joining $v_{0}$ to $\eta \in \partial_{\infty} T$. Then the uniform quasigeodesic paths $\gamma_{c(n)}$ combine to form a uniform quasigeodesic ray $\gamma_{\eta}$ in $X$ which projects monotonically to $c$.

For the following proof, we recall a notion from [BH99, Chapter III.H, p. 429]: A generalized geodesic ray in a metric space $Z$ is either a geodesic ray or a finite subinterval.

Proposition 7.8. Any (quasi)geodesic ray in $X$ starting from $x_{0}$ is asymptotic to a quasigeodesic ray of exactly one of the above two types.

Proof. Suppose that $\rho$ is a geodesic ray in $X$ emanating from $x_{0}$. For each $n \in \mathbb{N}$ let $\alpha_{n}=\beta\left(x_{0}, \rho(n)\right)$ be the arc-length parametrized HV quasigeodesic segment (discussed after Lemma 7.3), joining $x_{0}$ to $\rho(n)$. Note that $\alpha_{n}$ projects monotonically to the interval $\llbracket v_{0}, v_{n} \rrbracket$, where $v_{n}=\pi(\rho(n))$. Since $X$ is a proper metric space, the sequence of uniform quasigeodesic segments $\left(\alpha_{n}\right)$ subconverges to a (uniform) quasigeodesic ray, say $\alpha$, asymptotic to $\rho(\infty)$. Since each $\alpha_{n}$ projects to an interval in $T$, the projection of $\alpha$ to $T$ is a generalized geodesic ray.

There are two cases to consider.
Case 1: $\pi(\rho)$ has finite diameter. In this case the image of $\pi \circ \alpha$ is a finite geodesic segment in $T$, say $\llbracket v_{0}, v \rrbracket$. It follows from the nature of paths $\alpha_{n}$ that $\alpha \cap X_{v}$ is a geodesic ray. Now by Proposition 7.4, in order to connect $x_{0}$ to $\alpha(\infty)$, we can first connect $x_{0}$ to its nearest-point projection $x_{1}$ in $X_{v}$ and then connect $x_{1}$ to $\alpha(\infty) \in \partial_{\infty} X_{v}$ by a geodesic ray in $X_{v}$. The concatenation of such two paths is a HV quasigeodesic of type 1.

Case 2: $\pi(\rho)$ has infinite diameter. In this case the image of $\pi \circ \alpha$ is a geodesic ray $c=v_{0} \eta$ in $T$. We shall show that $\alpha=\rho_{\eta}$. It suffices to prove the claim for finite subsegments in $\alpha$.

Since each $\alpha_{n}$ is an HV path and $\pi \circ \alpha_{n}$ converges to a geodesic ray in $T$ it is clear that there is $v_{1} \in V(T)$ adjacent to $v_{0}$ such that for all large $n, \gamma_{v_{1}} \subset \alpha_{n}$. Then we can run the same argument by replacing $x_{0}$ by $x_{v_{1}}$. Thus by induction on $\pi \circ \alpha(n)$ we are done. By the construction, each subsegment of $\alpha$ connecting $x_{0}$ to $X_{v_{n}}, v_{n}=c(n)$, is the limit of a
sequence of HV quasigeodesic segments connecting $x_{0}$ to $X_{v_{n}}$. Thus, the limit is again an HV quasigeodesic segment connecting $x_{0}$ to $X_{v_{n}}$.

Lemma 7.9. Suppose $c:[0, \infty) \rightarrow T$ is a geodesic ray with $v_{n}=c(n), n \in \mathbb{N}$, and $c(\infty)=\eta$. Then every sequence $x_{n} \in X_{v_{n}}$ converges to $\gamma_{\eta}(\infty) \in \partial_{\infty} X$.

Proof. Let $\gamma_{n}$ denote the concatenation of the path $\gamma_{v_{n}}$ and the geodesic $\llbracket x_{v_{n}}, x_{n} \rrbracket_{X_{v n}}$. These concatenations are uniform quasigeodesics in $X$. Clearly, the sequence $\left\{\gamma_{n}\right\}$ converges uniformly on compacts to $\gamma_{\eta}$.

Our next goal is to describe the ideal boundary $\partial_{\infty} X$ in terms of ideal boundaries of vertex-spaces $\partial_{\infty} X_{v}$ and the ideal boundary of the tree $T$. Our description is similar to the one given by Dahmani, [Dah03, section 2], in the setting of graphs of hyperbolic groups.

We set

$$
\tilde{\mathcal{Z}}:=\coprod_{v \in V(T)} \partial_{\infty} X_{v}
$$

and define a relation $\sim$ on $\tilde{\mathcal{Z}}$ as follows:
If $\xi_{u} \in \partial_{\infty} X_{u}$ and $\xi_{v} \in \partial_{\infty} X_{v}$ then $\xi_{u} \sim \xi_{v}$ iff $\xi_{u}$ belongs to the ideal boundary flow $F l\left(\left\{\xi_{v}\right\}\right)$ of $\xi_{v}$ in $\partial_{\infty} X$, see Section 3.3.4. It follows from the discussion of ideal boundary flows in Section 3.3.4 that any two boundary flows are either equal or disjoint, hence, $\sim$ is an equivalence relation. We let $p: \tilde{\mathcal{Z}} \rightarrow \mathcal{Z}:=\tilde{\mathcal{Z}} / \sim$ be the quotient map. We will topologize $\mathcal{Z}$ later on. For now we note that, in general, this topology is not the quotient topology of the coproduct topology on $\tilde{\mathcal{Z}}$ (cf. Lemma 7.12), but the topology will restrict to the standard topology on each $\partial_{\infty} X_{v}$.

The space $\mathcal{Z}$ will be homeomorphic to one part of $\partial_{\infty} X$. The other part will be homeomorphic to $\partial_{\infty} T$ (with its natural topology of the ideal boundary of a tree). There are natural maps from both $\partial_{\infty} T$ and $\mathcal{Z}$ to $\partial_{\infty} X$ defined, respectively, as follows:

1. $f_{\partial_{\infty} T}: \eta \mapsto \gamma_{\eta}(\infty), \eta \in \partial_{\infty} T$.
2. Since each $X_{v}, v \in V(T)$, is qi embedded in $X$, we have topological embeddings

$$
q_{v}: \partial_{\infty} X_{v} \hookrightarrow \partial_{\infty} X
$$

By combining these embeddings, we obtain a map

$$
q: \coprod_{v \in V(T)} \partial_{\infty} X_{v} \rightarrow \partial_{\infty} X
$$

Next, for two vertical geodesic rays $\alpha_{u}$ in $X_{u}$ and $\alpha_{v}$ in $X_{v}(u, v \in V(T))$ we have equivalence of the following statements:
(a) $q_{u}\left(\alpha_{u}(\infty)\right)=q_{v}\left(\alpha_{v}(\infty)\right)$.
(b) $\operatorname{Hd}\left(\alpha_{u}, \alpha_{v}\right)<\infty$.
(c) The boundary flow-space $F l\left(\left\{\alpha_{u}(\infty)\right\}\right)$ contains $\alpha_{v}(\infty)$.

While the equivalence of (a) and (b) is immediate, the equivalence of (b) and (c) follows from Lemma 3.35(2).

Thus, the maps $q$ satisfies the property that $z_{1} \sim z_{2}$ iff $q\left(z_{1}\right)=q\left(z_{2}\right)$. In particular, the map $q$ descends to a map $f_{T}: \mathcal{Z} \rightarrow \partial_{\infty} X$. Combining the maps $f_{\partial_{\infty} T}, f_{T}$ we obtain a map

$$
f: \partial_{\infty} T \sqcup \mathcal{Z} \rightarrow \partial_{\infty} X
$$

Lemma 7.10. The map $f$ is a bijection.
Proof. 1. That $f_{\mathcal{Z}}$ is injective is immediate from the equivalence of (a) and (c) above.
2. If $\eta_{1}, \eta_{2} \in \partial_{\infty} T$ are distinct, then the rays $v_{0} \eta_{1}, v_{0} \eta_{2}$ in $T$ diverge, hence, their lifts $\gamma_{\eta_{1}}, \gamma_{\eta_{2}}$ in $X$ diverge as well. Hence, $\gamma_{\eta_{1}}(\infty) \neq \gamma_{\eta_{2}}(\infty)$. It follows that $f_{\partial_{\infty} T}$ is injective.
3. Proposition 7.8 directly implies that the images of $f_{\partial_{\infty} T}, f_{T}$ are disjoint and their union is the entire $\partial_{\infty} X$.

We next topologize the disjoint union of $\mathcal{Z}$ and $\partial_{\infty} T$ by defining a basis of this topology as follows. Given a vertex $v \in T$, we let the shadow $S h_{v}$ of $v$ in $V(T) \cup \partial_{\infty} T$ denote the set consisting of all $\xi \in \partial_{\infty} T$ and $w \in V(T)$ such that the rays $v_{0} \xi$ and segments $v_{0} w$ contain $v$.
(A) Let $\eta$ be a point in $\partial_{\infty} T$ and let $v$ be a vertex in the ray $v_{0} \eta$. Then define

$$
U_{v, \eta}:=\left(S h_{v} \cap \partial_{\infty} T\right) \sqcup \bigcup_{w \in S h_{v} \cap V(T)} p\left(\partial_{\infty} X_{v}\right) \subset \partial_{\infty} T \sqcup \mathcal{Z} .
$$

These subsets will form a basis of neighborhoods of $\eta$ in $\partial_{\infty} T \sqcup \mathcal{Z}$.
(B) Let [ $\zeta$ ] be a point in $\mathcal{Z}, R>0$. For each $\eta \in \partial_{\infty} T$ and $\zeta \in \partial_{\infty} X_{v}$ in the equivalence class [ $\zeta$ ] define the point $z_{\eta} \in X_{v}$ as $x_{v}$ if the ray $v_{0} \eta$ does not contain $v$, and so that $\left[x_{v} z_{\eta}\right]_{X_{v}}$ is the maximal subsegment of $\gamma_{\eta}$ contained in $X_{v}$. Similarly, define $z_{\eta}$ for points $\eta \in \partial_{\infty} X_{w}$ : If $\llbracket v_{0}, w \rrbracket$ is disjoint from $v$, then set $z_{\eta}:=x_{v}$, otherwise it is the maximal subsegment of the HV ray $\rho_{\eta}=\gamma_{w} \star x_{w} \eta$ contained in $X_{v}$.
(B1) We define $U_{R,[\zeta]}^{1}$ as the set of points $\eta \in \partial_{\infty} T$ such that there exists a representative $\zeta \in \partial_{\infty} X_{v}$ of [ $\zeta$ ] for which $\left(\eta \cdot z_{v}\right)_{x_{v}}>R$.
(B2) Similarly, define

$$
U_{R,[\zeta]}^{2}:=p\left(\left\{\eta \in \partial_{\infty} X_{v}:\left(\zeta . z_{v}\right)_{x_{v}}>R, \zeta \in[\zeta]\right\}\right) .
$$

Here in both (B1) and (B2) where the Gromov-product is taken in $X_{v}$. Set

$$
U_{R,[\zeta]}:=U_{R,[\zeta]}^{1} \cup U_{R,[\zeta]}^{2} .
$$

We leave it to the reader to check the following properties satisfied by the collection of basic subsets $U_{v, \eta}, U_{R,[\zeta]}$ defined above:

Lemma 7.11. 1. $\eta \in U_{v, \eta},[\zeta] \in U_{R,[\zeta]}$ for every $\eta, \zeta$, and $v, R$ as above.
2. For every two basis subsets $U^{\prime}, U^{\prime \prime}$ as above containing a point $\xi \in \partial_{\infty} T \sqcup \mathcal{Z}$, there exists another basis subset $U$ containing $\xi$ such that $U \subset U^{\prime} \cap U^{\prime \prime}$.
3. For any two distinct points $\xi^{\prime}, \xi^{\prime \prime} \in \partial_{\infty} T \sqcup \mathcal{Z}$, there exist disjoint basic subsets $U^{\prime}, U^{\prime \prime}$ containing $\xi^{\prime}, \xi^{\prime \prime}$ respectively.

It follows that the collection of basic sets $U_{\nu, \eta}, U_{R, \zeta}$ defines a Hausdorff topology $\tau$ on $\partial_{\infty} T \sqcup \mathcal{Z}$. From now on, we will equip $\partial_{\infty} T \sqcup \mathcal{Z}$ with this topology. We will see soon (Proposition 7.13) that the topology $\tau$ is compact and metrizable. The next lemma, where we use metrizability of $(\mathcal{Z}, \tau)$, describes some properties of $(\mathcal{Z}, \tau)$ :

Lemma 7.12. i. For every sequence of distinct vertices $v_{n} \in V(T)$ the sequence of compacts $p\left(\partial_{\infty} X_{v_{n}}\right)$ subconverges to a point in $\left(\partial_{\infty} T \sqcup \mathcal{Z}, \tau\right)$.
ii. For every finite diameter subtree $S \subset T$, the restriction of $\tau$ to $p\left(\coprod_{v \in V(S)} \partial_{\infty} X_{v}\right) \subset \mathcal{Z}$ is compact.

Proof. i. After extraction, there are two cases which may occur:
Case i1. There is a vertex $v_{0} \in V(S)$ such that all the edges $e_{n}=\left[v_{0}, w_{n}\right]$ in the segments $\llbracket v_{0}, v_{n} \rrbracket$ are pairwise distinct. Pick a base-point $x_{0} \in X_{v_{0}}$. Then, again by properness of $X$, the sequence of distances from $x_{0}$ to $X_{e_{n} v_{0}}\left(\right.$ in $X_{v_{0}}$ ) diverges to infinity. It follows that, after further extraction, the sequence of subsets $X_{e_{n} v_{0}}$ converges to a point $\xi \in \partial_{\infty} X_{v_{0}}$. By the description of the topology $\tau$, the sequence $\left(x_{n}\right)$ converges to $p(\xi) \in \mathcal{Z}$ as well.

Case i2. The sequence ( $v_{n}$ ) converges to a point $\eta \in \partial_{\infty} T$. Then, by the definition of the topology $\tau$, every sequence $\left(x_{n}\right)$ in $X_{v_{n}}$ converges to $\eta$.
ii. Since $(\mathcal{Z}, \tau)$ is metrizable, it suffices to prove sequential compactness. Consider a sequence $x_{n} \in X_{v_{n}}$ where $v_{n} \in V(S)$. There are two cases to consider:

Case ii1. Suppose that, after extraction, all the vertices $v_{n}$ are distinct. Then, by Part i (Case i1), the sequence $\left(x_{n}\right)$ subconverges to a point in $p\left(\partial_{\infty} X_{v}\right)$ for some $v \in V(S)$.

Case ii2. The same vertex $v$ appears in the sequence $\left(v_{n}\right)$ infinitely many times. Then, after extraction, $v_{n}=v$ and the sequence $\left(x_{n}\right)$ subconverges to a point in $\partial_{\infty} X_{v}$ (recall that $X$ is assumed to be proper, which implies properness of $X_{v}$ ).

We can now prove the main result of this section:
Proposition 7.13. The map $f: \partial_{\infty} T \sqcup \mathcal{Z} \rightarrow \partial_{\infty} X$ is a homeomorphism.
Proof. Since $\partial_{\infty} X$ is compact, $\partial_{\infty} T \sqcup \mathcal{Z}$ is Hausdorff and $f$ is a bijection, it suffices to prove continuity of $f^{-1}$.

Case 1. Suppose that $\eta_{n} \in \partial_{\infty} T$ are such that the sequence $\left(\gamma_{\eta_{n}}(\infty)\right)$ in $\partial_{\infty} X$ converges to $\gamma_{\eta}(\infty), \eta \in \partial_{\infty} T$. This implies that there exists a constant $D$ such that for every $R \geq 0$ and all sufficiently large $n$, the point $\gamma_{\eta}(R)$ lies in the $D$-neighborhood of $\gamma_{\eta_{n}}$. The same, therefore, holds for the rays $v_{0} \eta, v_{0} \eta_{n}$. That implies convergence $\eta_{n} \rightarrow \eta$.

Case 2. Suppose that $\xi_{n} \in \partial_{\infty} X_{w_{n}}$ is a sequence converging to $\xi=\rho_{\eta}(\infty)$. Then, for the same reason as in Case 1, the sequence ( $w_{n}$ ) converges to $\eta$ in $T \cup \partial_{\infty} T$. It then follows by the definition of a neighborhood basis at $\eta$ in $\mathcal{Z} \cup \partial_{\infty} T$ that $\xi_{n} \rightarrow \eta$.

Case 3. Suppose that $\eta_{n}$ is a sequence in $\partial_{\infty} T$ such that the corresponding sequence $\xi_{n}:=\gamma_{\eta_{n}}(\infty)$ converges to some $\xi \in \partial_{\infty} X_{v}$. Then, after extraction, the sequence of HV (uniformly quasigeodesic) rays $\gamma_{\eta_{n}}$ converges to an HV ray $\gamma$ asymptotic to $\xi$. This limiting ray necessarily has the form of a concatenation $\rho_{\xi^{\prime}} \gamma_{w} \star \alpha_{w}$, where $\alpha_{w}$ is a geodesic ray in a vertex space $X_{w}$. Since the rays $\gamma, \gamma_{\eta}$ are at finite Hausdorff distance from each other, it follows that $p(\xi)=p\left(\xi^{\prime}\right)$, i.e. $[\xi]=\left[\xi^{\prime}\right]$. Furthermore, let $\left[x_{v} z_{n}\right]_{X_{v}}$ is the maximal subinterval of $\gamma_{\eta_{n}}$ contained in $X_{v}$. Then

$$
\lim _{n \rightarrow \infty}\left(\xi^{\prime} \cdot z_{n}\right)_{x_{v}}=\infty
$$

Now, it follows from the definition of a neighborhood basis of [ $\xi$ ] in $\mathcal{Z} \sqcup \partial_{\infty} T$ (see the description of neighborhoods $U_{[\xi], R}^{1}$ ) that

$$
\lim _{n \rightarrow \infty} \eta_{n}=[\xi]
$$

in the topology of $\mathcal{Z} \sqcup \partial_{\infty} T$.
Case 4. The proof in the last case, when $\xi_{n} \in \partial_{\infty} X_{v_{n}}$ is a sequence converging to $\xi \in \partial_{\infty} X_{\nu}$ in $\partial_{\infty} X$ is similar to Case 3 and is left to the reader.

## CHAPTER 8

## Cannon-Thurston maps

In this chapter, as an application of the description of uniform quasigeodesics in trees of hyperbolic spaces, we establish an existence theorem for Cannon-Thurston maps (CTmaps) between ideal boundaries of trees of hyperbolic spaces induced by the inclusion maps of subtrees of spaces, $X_{S}=Y \rightarrow X$, Theorem 8.11. The proof of this theorem occupies most of the chapter. Once this theorem is proven, we investigate the associated Cannon-Thurston laminations. In Section 8.7 we identify the CT-lamination $\Lambda(Y, X)$, while in Section 8.9 we relate $\Lambda(Y, X)$ to the collection of ending laminations of $Y$ in $X$. We conclude the chapter with Section 8.11 where we discuss group-theoretic application our results on CT-maps and CT-laminations. In particular, in Section 8.11 .1 we construct examples of undistorted surface subgroups of $P S L(2, C) \times P S L(2, C)$ which are not Anosov. (The proof of non-distortion is an application of Theorem 8.19.)

### 8.1. Generalities of Cannon-Thurston maps

If $X, Y$ are nonempty geodesic hyperbolic spaces and $f: Y \rightarrow X$ is a qi embedding, then $f$ induces a (continuous) embedding of Gromov-boundaries, $\partial_{\infty} Y \rightarrow \partial_{\infty} X$ : A sequence $\left(y_{n}\right)$ in $Y$ is a Gromov-sequence if and only if $\left(f\left(y_{n}\right)\right)$ is a Gromov-sequence in $X$ (see e.g. [V0̈5, Theorem 5.38] or [DK18, Exercise 11.109]). The problem of existence of Cannon-Thurston maps concerns the existence of such an extension in the setting of uniformly proper maps.

The original motivation for Cannon-Thurston maps comes from the group theory: Given a hyperbolic subgroup $H$ of a hyperbolic group $G$ (with the inclusion map $\iota=\iota_{H, G}$ ) or, more generally, a homomorphism with finite $\operatorname{kernel} \phi: H \rightarrow G$ between two hyperbolic groups, one says that $\phi$ admits a Cannon-Thurston map if there exists a $\phi$-equivariant continuous map (a CT-map)

$$
\partial_{\infty} \phi: \partial_{\infty} H \rightarrow \partial_{\infty} G
$$

Surprisingly, CT-maps for group homomorphisms exist quite often (see [ $\mathbf{M j 1 4 a} \mathbf{M} \mathbf{M j 1 4 b}$, MP11, Mj16, Mj17, BR20], etc.) but not always (see [BR13]). One of the earliest examples (justifying the terminology) of existence of CT-maps is due to Cannon and Thurston, [CT07]: If $M$ is a compact hyperbolic 3-manifold fibered over the circle with the fiber $F$, then the natural embedding $\iota: \pi_{1}(F) \rightarrow \pi_{1}(M)$ admits a CT-map.

One can further generalize the setting of CT-maps to the non-equivariant one:
Defintition 8.1. Let $X, Y$ be geodesic Gromov-hyperbolic spaces and $f: H \rightarrow G$ is a coarse Lipschitz map. Then $f$ is said to admit a CT-map or admits a CT-extension, if there exists a map

$$
\partial_{\infty} f: \partial_{\infty} Y \rightarrow \partial_{\infty} X
$$

such that $f \cup \partial_{\infty} f: \bar{Y}=Y \cup \partial_{\infty} Y \rightarrow \bar{X}=X \cup \partial_{\infty} X$ is continuous on $\partial_{\infty} Y$.
In order to connect to the group-theoretic situation, one takes $X, Y$ to be Cayley graphs of the groups $G$ and $H$ respectively (where the finite generating set of $G$ contains that of
$H$ ), and $f: Y \rightarrow X$ the inclusion map induced by the inclusion $\phi=\iota: H \rightarrow G$. Since $f$ is equivariant, the existence of a CT-extension of $f$ would imply the existence of a continuous equivariant map $\partial_{\infty} \phi$.

In the setting when $Y$ is a subspace of $X$ with the induced path-metric and the identity embedding $f=\iota_{Y, X}$, we will use the notation $\partial_{Y, X}$ for the CT-map $\partial_{\infty} \iota_{Y, Y}$ (if it exists). The same notation $\partial_{H, G}$ will be used for the CT-map $\partial_{\infty} \iota_{H, G}$, where $\iota_{H, G}: H \hookrightarrow G$ is the identity embedding of a hyperbolic subgroup $H$ of a hyperbolic group $G$.

A criterion for the existence of CT-maps between hyperbolic metric spaces was established by Mahan Mitra in [Mit98, Lemma 2.1]. Recall that $(x . y)_{p}$ denotes the Gromovproduct in a metric space.

Theorem 8.2 (Mitra's Criterion). Let $f: Y \rightarrow X$ be a coarse Lipschitz proper map of proper geodesic hyperbolic metric spaces. Then a Cannon-Thurston map $\partial_{\infty} f: \partial_{\infty} Y \rightarrow$ $\partial_{\infty} X$ exists if and only if for some (each) $y_{0} \in Y$ the function

$$
t \mapsto \inf \left\{\left(f\left(y_{1}\right) \cdot f\left(y_{2}\right)\right)_{f\left(y_{0}\right)}: y_{1}, y_{2} \in Y \text { are such that }\left(y_{1} . y_{2}\right)_{y_{0}} \geq t\right\}
$$

is proper.
Half of this theorem (most relevant for us) also holds for non-proper and non-geodesic hyperbolic spaces. The result was first proven in [KS20], we include a proof since it is quite simple and for the sake of completeness:

Proposition 8.3. Suppose that $f: Y \rightarrow X$ is a coarse Lipschitz map of hyperbolic spaces in the sense of Gromov, such that for each $p \in Y$ and each pair of sequences $y_{n}, y_{n}^{\prime} \in Y$,

$$
\lim _{n \rightarrow \infty}\left(y_{n} \cdot y_{n}^{\prime}\right)_{p}=\infty \Rightarrow \lim _{n \rightarrow \infty}\left(f\left(y_{n}\right) \cdot f\left(y_{n}^{\prime}\right)\right)_{f(p)}=\infty
$$

## Then $f$ admits a Cannon-Thurston map.

Proof. Note that the assumption in the proposition implies that the map $f$ is metrically proper: If a sequence $y_{n} \in Y$ diverges to infinity in the sense that $d\left(p, y_{n}\right) \rightarrow \infty$, then the sequence $f\left(y_{n}\right)$ also diverges to infinity. To prove properness one takes a sequence $y_{n}^{\prime}=y_{n}$.

The definition of the Cannon-Thurston extension of the map $f$ is a natural one. The assumption in the proposition states that the image under $f$ of each Gromov-sequence $\left(y_{n}\right)$ in $Y$ is also a Gromov-sequence in $X$. Thus, one defines the extension by the formula:

$$
\partial_{\infty} f\left(\left[y_{n}\right]\right)=\left[f\left(y_{n}\right)\right],
$$

where $\left(y_{n}\right)$ is a Gromov-sequence. A diagonal argument shows that this map is well defined and, hence, is partially continuous: If a sequence $y_{n} \in Y$ converges to $\zeta \in \partial_{\infty} Y$, then the sequence $f\left(y_{n}\right)$ converges to $\partial_{\infty} f(\zeta)$. From this, by the density of $Y$ in $\bar{Y}$, it follows that $f \cup \partial_{\infty} f$ is continuous at $\partial_{\infty} Y$.

Remark 8.4. The converse to this proposition also holds if $Y$ is proper: If a map $f: Y \rightarrow X$ admits a CT-extension, then for every pair of sequences $\left(y_{n}\right),\left(y_{n}^{\prime}\right)$ in $Y$,

$$
\lim _{n \rightarrow \infty}\left(y_{n} \cdot y_{n}^{\prime}\right)_{p}=\infty \Rightarrow \lim _{n \rightarrow \infty}\left(f\left(y_{n}\right) \cdot f\left(y_{n}^{\prime}\right)\right)_{f(p)}=\infty
$$

The reason is that such sequences $\left(y_{n}\right),\left(y_{n}^{\prime}\right)$ have to subconverge to points $\xi, \xi^{\prime} \in \partial_{\infty} Y$ (in view of properness of $Y$ ). Then, necessarily, $\xi=\xi^{\prime}$. Since $f$ admits a CT-extension to the points $\xi, \xi^{\prime}$, the sequences $\left(f\left(y_{n}\right)\right),\left(f\left(y_{n}^{\prime}\right)\right)$ have to converge to $\partial_{\infty} f(\xi)$, implying that

$$
\lim _{n \rightarrow \infty}\left(f\left(y_{n}\right) \cdot f\left(y_{n}^{\prime}\right)\right)_{f(p)}=\infty .
$$

In the next lemma we will use the notion of the relative boundary $\partial_{\infty}(A, X)$ of a subset $A$ of a hyperbolic space $X$, see Definition 1.81.

Lemma 8.5. Suppose that $Y$ is a proper metric space, and $f: Y \rightarrow X$ admits a CTextension. Then

$$
\partial_{\infty} f\left(\partial_{\infty} Y\right)=\partial_{\infty}(f(Y), X)
$$

Proof. By the continuity of the CT-extension, if a sequence $y_{n} \in Y$ converges to $\xi \in \partial_{\infty} Y$, then the sequence $\left(f\left(y_{n}\right)\right)$ converges to $\partial_{\infty} f(\xi)$. Conversely, suppose that a sequence $x_{n}=f\left(y_{n}\right) \in f(Y)$ converges to a point $\eta \in \partial_{\infty}(f(Y), X)$. By the properness of $Y$, the sequence $\left(y_{n}\right)$ subconverges to some $\xi \in \partial_{\infty} Y$ and, again by continuity of the CT-extension, $\partial_{\infty} f(\xi)=\eta$.

Lemma 8.6 (Functoriality of CT-maps). If $f: X \rightarrow Y, g: Y \rightarrow Z$ are coarse Lipschitz maps which admits CT-extensions, then their composition also does and

$$
\partial_{\infty}(g \circ f)=\partial_{\infty} g \circ \partial_{\infty} f
$$

Proof. Let $\left(x_{n}\right)$ be a Gromov-sequence representing $\xi \in \partial_{\infty} X$. Then its image, the sequence $\left(y_{n}\right)$ in $Y$ is also a Gromov-sequence in $Y$ representing the point $\eta=\partial_{\infty} f(\xi)$. Applying the same reasoning to the map $g$, we conclude that $\left(g\left(y_{n}\right)\right)$ is a Gromov sequence in $Z$ representing $\zeta=\partial_{\infty} g(\eta)$. Thus, $\partial_{\infty} g \circ \partial_{\infty} f$ defines the CT-extension of $g \circ f$.

Since for $\delta$-hyperbolic spaces in the sense of Rips, the Gromov-product is comparable to the distance to a suitable geodesic (see Lemma 1.46), Proposition 8.3 can be reformulated as

Proposition 8.7. Suppose that $f: Y \rightarrow X$ is a coarse Lipschitz map of hyperbolic spaces in the sense of Rips, such that for each pair of sequences $y_{n}, y_{n}^{\prime} \in Y$, if

$$
\lim _{n \rightarrow \infty} d_{Y}\left(p,\left[y_{n} y_{n}^{\prime}\right]_{Y}\right)=\infty R A \lim _{n \rightarrow \infty} d_{X}\left(f(p),\left[f\left(y_{n}\right) f\left(y_{n}^{\prime}\right)\right]_{X}\right)=\infty .
$$

## Then $f$ admits a Cannon-Thurston map.

The existence of a CT-map, of course, does not imply its injectivity, and the notion of a Cannon-Thurston lamination (introduced by Mitra in [Mit97]) is motivated by this lack of injectivity:

Definition 8.8. Suppose that $f: Y \rightarrow X$ is a map of hyperbolic spaces which admits a CT-extension $\partial_{\infty} f$. The Cannon-Thurston lamination (the CT-lamination) of $f: Y \rightarrow X$ is the (closed) subset $\Lambda(f)$ of $\partial_{\infty}^{(2)} Y$ consisting of unordered pairs of distinct points $\{\xi, \eta\}$ such that $\partial_{\infty} f(\xi)=\partial_{\infty} f(\eta)$. In the case when $Y$ is a subset of $X$ and $f$ is the inclusion map $Y \rightarrow X$, we will use the notation $\Lambda(Y, X)$ for the CT-lamination. A geodesic $\alpha \subset Y$ connecting points $\xi, \eta$ with $\{\xi, \eta\} \in \Lambda(f)$, is called a leaf of the CT-lamination $\Lambda(f)$.

Note that, in view of the fact that the map $\partial_{\infty} f$ is continuous, the lamination $\Lambda(f)$ is a closed subset of $\partial_{\infty}^{(2)} Y$.

Remark 8.9. 1. The above definition of $\Lambda(f)$ requires existence of a CT-map. However, one can extend this definition to the general case as follows (see [Mit99, section 2], [MR18, Definition 3.1]). We say that a point $\left\{\xi, \xi^{\prime}\right\} \in \partial_{\infty}^{(2)} Y$ belongs to $\Lambda(f)$ if there exist sequences $\left(y_{n}\right),\left(y_{p}^{\prime}\right)$ in $Y$ converging to $\xi, \xi^{\prime}$ respectively, such that

$$
\lim _{n \rightarrow \infty}\left(f\left(y_{n}\right) \cdot f\left(y_{n}^{\prime}\right)\right)_{f(p)}=\infty
$$

2. As it was noted in [MR18], in the general setting, $\Lambda(f)$, a priori is not closed in $\partial_{\infty}^{(2)} Y$. If the map $f$ admits a CT-extension, then the two definitions of $\Lambda(f)$ agree.
3. If $H$ is a hyperbolic subgroup of a hyperbolic group $G$ and $f$ is the inclusion map $H \rightarrow G$ then $\Lambda(f)=\emptyset$ if and only if $H$ is quasiconvex in $G$, see [Mit99, Lemma 2.1].

Mitra proved in [Mit98] that if $G$ is a hyperbolic group isomorphic to the fundamental group of a finite graph $\mathcal{G}$ of hyperbolic groups satisfying the conditions of the BestvinaFeighn Combination Theorem, then for each vertex-group $G_{v}$ of $\mathcal{G}$, the Cannon-Thurston map for the inclusion homomorphism $G_{v} \rightarrow G$ exists. More generally, he proves:

Theorem 8.10. If $X \rightarrow T$ is a tree of hyperbolic spaces with hyperbolic total space $X$, then for every vertex space $X_{v}$ the inclusion map $X_{v} \rightarrow X$ admits a CT-map.

Later on, in the paper by Mj and Pal [MP11], this result was extended to the relatively hyperbolic setting; we will discuss the extension in the next chapter of the book.

Our goal is to generalize Theorem 8.10 to the case of fundamental groups of subgraphs of graphs of groups and, more generally, to inclusion maps $Y \rightarrow X$ of subtrees of spaces in a tree of hyperbolic spaces $\mathfrak{V}) \subset \mathfrak{X}$, satisfying the conditions of Theorem 2.58. The main result of this chapter is:

Theorem 8.11. Let $\mathfrak{X}=(\pi: X \rightarrow T)$ be a tree of hyperbolic spaces with hyperbolic total space $X$. Then for every subtree $S \subset T$, the inclusion map $X_{S} \rightarrow X$ admits a CTextension.

The most difficult part of the proof is to relate, for points $x, y \in Y$, the geodesics $[x y]_{X}$ in $X$ to the geodesics $[x y]_{Y}$ in $Y$. This is done in Section 8.2 in the form of a "cut-andreplace" theorem (Theorem 8.19). Once this theorem is established, the existence of a CT-map is an almost immediate consequence of Proposition 8.7 (see Theorem 8.46). The main tool in our proof of Theorem 8.19 is the description of geodesics in hyperbolic trees of spaces given in the previous chapter. As this description is inductive in nature (a 7 -step process), the proof of the cut-and-replace theorem follows the same inductive process (but we will only need 6 steps). While our proof follows in main Mitra's proof in [Mit98], we have to deal with some substantial complications; in fact, we will derive Mitra's theorem (Theorem 8.10) as an easy application of the first part of our proof, see the end of Section 8.3.

In the proof of Theorem 8.19 we will be using the fact that $\mathfrak{X}$ satisfies the uniform $K$-flaring condition for all $K \geq 1$ (see Lemma 2.46). Of course, if $\mathfrak{X}$ satisfied the $K$-flaring condition, so does $\mathfrak{V} \subset \mathfrak{X}$.

### 8.2. Cut-and-replace theorem

8.2.1. Definitions and notations. Suppose that $\mathfrak{X}=(\pi: X \rightarrow T)$ is a tree of spaces (not necessarily hyperbolic), containing a subtree of spaces $\mathfrak{Y}=\left(\pi: X_{S}=Y \rightarrow S\right)$. In the next section we shall prove that the inclusion $Y \rightarrow X$ admits a Cannon-Thurston map $\partial_{\infty} Y \rightarrow \partial_{\infty} X$ provided that $X$ is hyperbolic. To prove this result we need to compare the $Y$-geodesics $[x y]_{Y}$ to $X$-geodesics $[x y]_{X}$ joining pairs points $x, y \in Y$. When the points are in the same vertex space in $Y$, this is done by Mahan Mitra in [Mit98] by constructing ladders. In general, up to a uniformly bounded error, the relation between $X$-geodesics and $Y$-geodesics is given by a cut-and-replace procedure described below.

For each (continuous) path $c: I \subset \mathbb{R} \rightarrow X$ in $X$ with $c(\partial I) \subset Y$, we define the following modification, a cut-and-replace procedure, transforming $c$ to a new path $\hat{c}=c_{S}: I \rightarrow Y$.

Definition 8.12. For a closed subinterval $J=\left[s, s^{\prime}\right] \subset I$, we say that the restriction $\zeta=\left.c\right|_{J}$ is a detour subpath in $c$, if $c(\partial J) \subset Y$, while $c(J-\partial J)$ is disjoint from $Y$. Thus, the points $x=c(s), x^{\prime}=c\left(s^{\prime}\right)$ belong to a common vertex-space $X_{t} \subset Y$. We then replace each detour subpath $\zeta$ in $c$ by the corresponding $X_{t}$-geodesic $\hat{\zeta}=\left[x x^{\prime}\right]_{X_{t}}$, called a replacement segment. ${ }^{1}$ We let $\hat{c}=c_{S}$ denote the resulting path $I \rightarrow Y$.

Figure 25. Detours and path-modification

Definition 8.13. Let $\phi$ be a continuous $\Lambda$-quasigeodesic in $X$ with the end-points in $Y$. We will say that $\phi$ is $\Lambda^{\prime}$-consistent if $\hat{\phi}$ is a $\Lambda^{\prime}$-quasigeodesic in $Y$. We will say that a pair of points $\left(y, y^{\prime}\right) \in Y^{2}$ is $\theta$-consistent, where $\theta$ is a function $[1, \infty) \rightarrow[1, \infty)$, if every continuous $\Lambda$-quasigeodesic $\phi$ in $X$ connecting $y$ to $y^{\prime}$ is $\theta(\Lambda)$-consistent. We say that a subset of $Y^{2}$ is (uniformly) consistent if it consists of $\theta$-consistent pairs for some function $\theta$. We will say that a pair of points $\left(y, y^{\prime}\right) \in Y^{2}$ is $\Lambda^{\prime}$-weakly consistent if $y, y^{\prime}$ are connected by some $\Lambda^{\prime}$-consistent continuous quasigeodesic in $X$. Similarly, we will say that a subset of $Y^{2}$ is uniformly weakly consistent if it consists of $\Lambda^{\prime}$-weakly consistent pairs of points for some $\Lambda^{\prime}$.

While it is clear that every consistent pair of points is also $\Lambda^{\prime}$-consistent for some $\Lambda^{\prime}$, it is far from clear that if a subset of $Y^{2}$ consisting of $\Lambda^{\prime}$-consistent pairs is uniformly consistent. The issue is that while any two uniform quasigeodesics $\phi, \phi^{\prime}$ connecting $y$ to $y^{\prime}$ are uniformly close, we do not yet know if the same holds for $\hat{\phi}, \hat{\phi}^{\prime}$. We will prove the claim, establishing equivalence of weak consistency and consistency, at the end of Part I of the proof of Theorem 8.19. Before that, we will be only proving consistency of specific quasigeodesics, namely slim combing paths $c\left(y, y^{\prime}\right)$ described in Section 7.1.

We will frequently use the following simple observation:
Remark 8.14. Suppose that a pair $(x, y) \in Y^{2}$ in $X$ is $\Lambda^{\prime}$-consistent. Then every pair of points $x^{\prime}, y^{\prime} \in N_{r}\left([x y]_{X}\right) \cap Y$ is $\theta^{\prime}$-consistent, where $\theta^{\prime}$ depends only on $\theta^{\prime}$ and $r$. In particular, perturbing the points $x, y$ by a uniformly bounded amount, we do not loose consistency of the pair.

[^13]Definition 8.15. Given two subsets $Z^{\prime}, Z^{\prime \prime}$ of a Gromov-hyperbolic space $Z$, we say that $y \in Z$ is an $R$-transition point between $Z^{\prime}, Z^{\prime \prime}$ in $Z$, if every geodesic in $Z$ connecting $Z^{\prime}, Z^{\prime \prime}$ passes within distance $R$ from $y$. We say that a finite sequence of points $z^{\prime}=z_{1}, z_{2}, \ldots, z_{n+1}=z^{\prime \prime}$ in a $\delta$-hyperbolic space $Z$ is $R$-straight if the geodesic $\gamma=z^{\prime} z^{\prime \prime} \subset Z$ passes through some points $x_{i} \in B\left(z_{i}, R\right)$ in the order $x_{2}, \ldots, x_{n}$.

In relation to (sub)trees of spaces $Y \subset X$, we will talk about $X$-transition points and $Y$-transition points. We will say that $y \in Y$ is an $R$-transition point between $Z^{\prime}, Z^{\prime \prime} \subset Y$ if it is $R$-transition point for $Z^{\prime}, Z^{\prime \prime}$ regarded as subsets in both $Y$ and $X$.

When dealing with sets of finite sequences, we will refer to those as uniformly straight if they are $R$-straight for some uniform value of $R$. We use a similar terminology for transition points.

Example 8.16. Suppose that $Z, Z^{\prime}$ are $\lambda$-quasiconvex and $C$-cobounded subsets in a $\delta$-hyperbolic geodesic space $X$. Let $\beta$ be a shortest geodesic between $Z$ and $Z^{\prime}$. Then every point of $\beta$ is an $R$-transition point between $Z$ and $Z^{\prime}$ with $R=R(C, \lambda, \delta)$. Conversely, every $R$-transition point between such $Z, Z^{\prime}$ is $D$-uniformly close to a point in $\beta$, where $D=D(C, B, \delta, R)$.

The importance of the concept of a transition point comes from another simple observation. Let $\mathfrak{X}$ be a tree of spaces and $\mathfrak{Y} \subset \mathfrak{X}$ be a subtree of spaces.

Lemma 8.17. Suppose that $Z_{1}, Z_{2} \subset X$ and $y \in Y$ is an $R$-transition point between $Z_{1}, Z_{2}$. Assume that the set of pairs $\left(z_{i}, y\right), z_{i} \in Z_{i}, i=1,2$, is $\theta$-consistent. Then the set of pairs $\left(z_{1}, z_{2}\right) \in Z_{1} \times Z_{2}$ is $\theta^{\prime}$-consistent where $\theta^{\prime}=\theta^{\prime}(L, R)$.

Proof. Since we are dealing with quasigeodesics, we can as well consider $L$-quasigeodesics $c$ in $X$ connecting point $z_{1} \in Z_{1}$ to $z_{2} \in Z_{2}$ and passing through $y$ (such exist due to the assumption that $y$ is an $R$-transition points in $X$ ). Such $c$ is a concatenation $c_{1} \star c_{2}$, where $c_{1}$ connects $z_{1}$ to $y$. Thus, since $y \in Y$,

$$
\hat{c}=\hat{c}_{1} \star \hat{c}_{2} .
$$

Each of the subpaths $\hat{c}_{i}$ is a $\theta(L)$-quasigeodesic by the consistency assumption for the pairs $\left(z_{i}, y\right)$. We will estimate the qi constant of $\hat{c}$ in $Y$. Let $\gamma$ be a geodesic in $Y$ connecting two points $a, b$ in $\hat{c}$; the only interesting case to consider is when $a \in \hat{c}_{1}, b \in \hat{c}_{2}$. Let $\hat{c}(a, b)$ be the portion of $\hat{c}$ between $a$ and $b$. Since $y$ is an $R$-transition point in $Y$ between $z_{1}, z_{2}$, the path $\gamma$ has to pass within distance $r=r(R, L)$ from $y$. Subdividing $\gamma$ as a concatenation $\gamma_{1} \star \gamma_{2}$, where $\gamma_{1}$ connects $z_{1}$ to $x \in B(y, r), i=1,2$, we see that

$$
\text { length }(\hat{c}(a, b)) \leq(\theta(L)+r) \text { length }(\gamma),
$$

as required by a uniform quasigeodesic. ${ }^{2}$
This lemma generalizes to the case of higher number of transition/concatenation points. Since the proof is similar, we leave it to the reader:

Lemma 8.18. Suppose that $z^{\prime}=z_{1}, z_{2}, \ldots, z_{n+1}=z^{\prime \prime}$ is an $R$-straight sequence in both $X$ and $Y$, and that each pair of points $\left(z_{i}, z_{i+1}\right), i=1, \ldots, n$, is $\theta$-consistent. Then the pair ( $z^{\prime}, z^{\prime \prime}$ ) is $\theta^{\prime}$-consistent with the function $\theta^{\prime}$ depending only on the hyperbolicity constant of $Y$ and on $\theta$.

We are now ready to state the main technical result of this chapter:

[^14]Theorem 8.19 (Cut-and-replace $X$-quasigeodesics to get $Y$-quasigeodesics). Suppose that $\mathfrak{X}=(\pi: X \rightarrow T)$ is a tree of hyperbolic spaces satisfying the uniform $K_{*}$-flaring condition, $S \subset T$ is a subtree and $Y=X_{S}$. Then $Y \times Y$ is $\theta$-consistent with $\theta$ depending only on the parameters of $\mathfrak{X}$.

We break the proof of Theorem 8.19 in three parts and each part in several steps, where we prove this theorem in special cases and then use these special cases to prove the general case in the last part.

### 8.3. Part I: Consistency of points in vertex flow-spaces

Suppose that $k \geq k_{5.2}, K=K_{5.2}(k)$, and that $\mathfrak{X}$ is a tree of hyperbolic spaces satisfying the uniform $\kappa_{4.5}(K)$-flaring condition. (As it was noted earlier, in Lemma 2.46, uniform $\kappa$-flaring holds for all $\kappa$ 's if $X$ is hyperbolic.) The main result of this section is:

Proposition 8.20. For every $u \in V(S)$, the set of pairs $\left(y, y^{\prime}\right) \in F l_{Y, k}\left(X_{u}\right) \times F l_{Y, k}\left(X_{u}\right)$ is $\theta=\theta_{8.20, k}$-consistent, with $\theta$ depending only on $k$ and the parameters of $\mathfrak{X}$.

Proof. For most of the proof we will be only proving weak uniform consistency, working with the quasigeodesic paths $c=c_{X}\left(y, y^{\prime}\right)$ in the fiberwise $4 \delta_{0}$-neighborhood of $\mathfrak{F} l_{X, k}\left(X_{u}\right) \subset \mathfrak{Y}$ given by the slim combing of $\mathfrak{F} l_{X, k}\left(X_{u}\right)$ described in Section 7.1.

According to Corollary 5.12, there exists a $(K, D, E)$-ladder $\left.\mathfrak{E}=\mathfrak{L}_{X}(\alpha) \subset \mathfrak{Y}\right)$ contained in the fiberwise $4 \delta_{0}$-neighborhood of $\mathfrak{F} l_{X, k}\left(X_{u}\right) \subset \mathfrak{Y}$, containing $y$ (resp. $y^{\prime}$ ) in its bottom (resp. top), where $K, D, E$ depend only on $k$ and $\alpha$ is a geodesic in $X_{u}$. Recall that, by the very definition, $c_{X}\left(y, y^{\prime}\right)=c_{\mathfrak{Q}}\left(y, y^{\prime}\right)$ is contained in the ladder $L_{X}(\alpha)$. Define $\mathfrak{L}_{Y}=\mathfrak{Z} \cap \mathfrak{Y}$ : It follows from the definition of a ladder that $\mathfrak{L}_{Y}$ is a $(K, D, E)$-ladder in $\mathfrak{Y}$. It also follows from the definition of the modification $c \mapsto \hat{c}$, that $\hat{c}$ is contained in $L_{Y}$ (up to a uniformly bounded error which we will ignore).

There are several cases to consider, according to the construction of uniformly quasigeodesic paths $c_{\mathfrak{R}}\left(y, y^{\prime}\right)$, depending on the properties of the ladder $\mathfrak{L}$ and location of the points $y, y^{\prime}$.
8.3.1. Part I.1: The points $y, y^{\prime}$ belong to a $\left(K, M_{\bar{K}}\right)$-narrow carpet $\mathfrak{A}=\mathfrak{H}_{X}=(\pi$ : $\left.A_{X} \rightarrow \llbracket u, w \rrbracket\right) \subset \mathfrak{L}_{X}$. The carpet $\mathfrak{A}$ contains the "subcarpet" $\mathfrak{A}_{Y}=\mathfrak{H}_{X} \cap \mathfrak{V}$, $\llbracket u, w^{\prime} \rrbracket=\pi\left(A_{Y}\right)$. Note that $\mathfrak{A}_{Y}$ is a $(K, C)$-carpet where $C$ the length of the "narrow end" $A_{w^{\prime}}$ of $\mathfrak{A}_{Y}$, but we cannot bound $C$ (from above) in terms of $k$. According to Corollary 3.63, we have the coarse $L_{3.63}$-Lipschitz retraction $\rho_{\mathfrak{A}}: X \rightarrow A_{X}$, where $L_{3.63}$ depends only on $K, D$ and $E$ (hence, only on $k$ ). The restriction of this retraction to $Y$ is a retraction to $A_{Y}$; in particular, $A_{Y}$ is $L_{3.63}$-qi embedded in $Y$.

Lemma 8.21. The pairs $\left(y, y^{\prime}\right)$ are $\Lambda_{8.21}$-weakly consistent, where $\Lambda_{8.21}$ depends only on $k$.

Proof. We let $\gamma_{y}, \gamma_{y^{\prime}}$ denote the $K$-leaves in $\mathfrak{A}_{X}$ connecting, respectively, $y, y^{\prime}$ to points of $A_{w}$. Let $v \in \llbracket u, w \rrbracket$ be the infimum of all vertices $t$ in $\llbracket u, w \rrbracket$ such that

$$
d_{X_{t}}\left(\gamma_{y}(t), \gamma_{y^{\prime}}(t)\right) \leq M_{\bar{K}}
$$

Then $c=c_{\mathfrak{R}}\left(y, y^{\prime}\right)$ is the concatenation of the subpath $\gamma_{y}$ restricted to $\llbracket u, v \rrbracket$, followed by the vertical geodesic $\left[\gamma_{y}(v) \gamma_{y^{\prime}}(v)\right]_{X_{v}}$ and then followed by $\gamma_{y^{\prime}}$ restricted to $\llbracket v, \pi\left(y^{\prime}\right) \rrbracket$. The path $\hat{c}$ is a similar concatenation $c_{1} \star c_{2} \star c_{3}$ except $v$ is replaced by the vertex $v^{\prime}$ which is the minimum of $\left\{v, w^{\prime}\right\}$ in the oriented interval $\llbracket u, w \rrbracket$ (the paths $c_{1}, c_{3}$ are contained in $\gamma_{y}, \gamma_{y^{\prime}}$ respectively and $c_{2}$ is contained in $\left.A_{\nu^{\prime}}\right)$. But this path is exactly the path $c_{\mathfrak{A}_{Y}}\left(y, y^{\prime}\right)$ as defined in Step I. 1 in Section 7.1, or in the proof of Proposition 4.1.

The quasigeodesic constant of $c_{\mathfrak{N}_{Y}}\left(y, y^{\prime}\right)$ a priori depends on both $K$ and $C$. However, according to Remark 4.3, the dependence on $C$ appears only in the proof of Lemma 4.2, establishing uniform bounds on distortion of paths $c_{\mathscr{R}_{Y}}\left(y, y^{\prime}\right)$ in $A_{Y}$. It remains, therefore, to get a uniform distortion bound depending only on $k$. Take a pair of points $a, b \in \hat{c}$. There are several cases to consider depending on the location of the points $a, b$, we will treat just one since the rest are done by the same argument: We will assume that $a \in c_{2}, b \in c_{3}$. It suffices to bound the length of $\hat{c}(a, b)$ (between $a, b)$ in terms of $d_{\mathfrak{N}}(a, b)$, equivalently, in terms of the length of $c(a, b)$ since the latter is a uniform (with quasigeodesic constant depending only on $k$ ) quasigeodesic in $A_{X}$. The latter path is a concatenation of $c\left(a, a^{\prime}\right)$ and $c\left(a^{\prime}, b\right)$, where $a^{\prime}$ is in $A_{v^{\prime}}$ and $c\left(a^{\prime}, b\right)=c_{3}$. See Figure 26. We have

$$
\text { length }\left(c_{3}\right) \leq \text { length }(c(a, b)),
$$

while

$$
\text { length }\left(c_{2}\right)=d_{A_{v^{\prime}}}\left(a, a^{\prime}\right) \leq \eta\left(d_{X}\left(a, a^{\prime}\right)\right) \leq \eta(\text { length }(c(a, b)))
$$

where $\eta=\eta_{2.17}$. Thus,

$$
\text { length }(\hat{c}(a, b)) \leq \text { length }(c(a, b))+\eta(\text { length }(c(a, b))
$$

thereby providing the required distortion bound depending only on $k$.

Figure 26
8.3.2. Part I.2: The points $y, y^{\prime} \in Y$ belong to a carpeted $X$-ladder $\mathfrak{R}=\mathfrak{R}_{X}(\alpha)$. In this part of the proof we assume that $\mathfrak{L}$ contains a $\left(K, M_{\bar{K}}\right)$-narrow carpet $\mathfrak{A}=\mathfrak{A}_{X}\left(\alpha^{\prime}\right)$, where $\alpha$ is a geodesic segment in $X_{u}, u \in S$, and $\alpha^{\prime} \subset \alpha$ is a subsegment of length $\geq$ length $(\alpha)-M_{\bar{K}}$. The path $c=c_{\mathfrak{Q}}\left(y, y^{\prime}\right)$ can be of one of two types (see Section 7.1, Step I.2, for the definition of the types of slim combing paths in a ladder):

1. If $c$ is of type 1 , then the assumption that $y, y^{\prime}$ are in $Y$ and the definition of type 1 paths imply that $c=\hat{c}$, so there is nothing to prove.
2. Suppose that $c$ is of type 2. Then $c$ is the concatenation $c_{1} \star c_{2} \star c_{3}$, where $c_{2}$ is contained in the carpet $\mathfrak{A}, c_{1}, c_{3}$ are contained in $Y$ and, thus,

$$
\hat{c}=c_{1} \star \hat{c}_{2} \star c_{3} .
$$

Below we will use the same notation for the subcarpet $\mathfrak{A}_{Y}=\mathfrak{A} \cap \mathfrak{Y}$ as in Part I.1.
Lemma 8.22. The pairs $\left(y, y^{\prime}\right)$ are $\Lambda_{8.22}$-weakly consistent, where $\Lambda_{8.22}$ depends only on $k$.

Proof. The paths $c_{1}, c_{3}$ are uniformly quasigeodesic in $L_{X}$ (since $c$ is) while $\hat{c}_{2}$ is uniformly quasigeodesic in $A_{Y}$ according to Lemma 8.21. Since $L_{Y}$ is uniformly hyperbolic, in order to prove the lemma, it suffices to verify that $\hat{c}$ is uniformly proper in $L_{Y}$ (see Lemma 1.20). The proof is similar to the one in Lemma 8.21. We will prove uniform properness of $\hat{c}$ in $L_{X}$. As in the proof of Lemma 8.21, we only consider the most representative case, of points $a \in c_{2}, b \in c_{3}$ : We need to bound length $(\hat{c}(a, b))$ in terms of length $(c(a, b))$. The path $c(a, b)$ is the concatenation $c\left(a, a^{\prime}\right) \star c_{3}\left(a^{\prime}, b\right)$, where $a^{\prime}$ is the concatenation point of $c_{2}$ and $c_{3}$. According to Lemma 8.21,

$$
\begin{array}{r}
\text { length }\left(\hat{c}\left(a, a^{\prime}\right)\right) \leq \Lambda_{8.21} d_{\mathfrak{A}_{Y}}\left(a, a^{\prime}\right) \leq \Lambda_{8.21} \eta_{2.17}\left(d_{\mathfrak{I}}\left(a, a^{\prime}\right)\right) \\
\leq \Lambda_{8.21} \eta_{2.17}(\text { length }(c(a, b))),
\end{array}
$$

while

$$
\text { length } \left.\left(c_{3}\right)\right) \leq \text { length }(c(a, b))
$$

Lemma follows.
8.3.3. Part I.3: General ladders. Suppose that $u \in S, \alpha=\left[p p^{\prime}\right]_{X_{u}} \subset Y, \mathfrak{L}=\mathfrak{L}_{X}(\alpha) \subset$ $\mathfrak{X}$ is a $K$-ladder, $\mathfrak{L}_{Y}=\mathfrak{L} \cap \mathfrak{Y}$. Our goal is to prove uniform consistency of paths $c_{\mathfrak{Q}}$ connecting points $y \in \operatorname{bot}(\mathfrak{L}) \cap Y, y^{\prime} \in \operatorname{top}(\mathfrak{L}) \cap Y$. Recall that according to Proposition Proposition 4.11 (on vertical subdivision), we have a subdivision of $\alpha$ into subintervals $\alpha_{i}=\left[p_{i} p_{i+1}\right]_{X_{u}}$, subintervals $\alpha_{i}^{\prime} \subset \alpha_{i}$, and a collection of $K$-qi sections $\Sigma_{i}$ in $\mathfrak{L}$ through the points $p_{i}$ dividing $\mathfrak{L}$ into subladders $\mathfrak{L}^{i}=\mathfrak{L}\left(\alpha_{i}\right)$ containing $\left(K, M_{\bar{K}}\right)$-narrow carpets $\mathfrak{A}^{i}=\mathfrak{A}\left(\alpha_{i}^{\prime}\right)$. We also defined points $x_{i}^{ \pm}$in the sections $\Sigma_{i}^{-}=\Sigma_{i}, \Sigma_{i}^{+}=\Sigma_{i+1}$ bounding $\mathfrak{Q}^{i}$ such that the combing paths in $L$ (connecting $y, y^{\prime}$ ) pass through the points $x_{i}^{ \pm}$. Each section $\Sigma_{i}$ is defined over some subtree $T_{i} \subset T$. The intersections $\Sigma_{i, Y}=\Sigma_{i} \cap Y$ project to subtrees $S_{i} \subset T_{i}$.

We next find uniform transition points in $Y$ between the sections $\Sigma_{i, Y}$. We let $v_{i}^{ \pm}=$ $\pi\left(x_{i}^{ \pm}\right)$and define vertices $w_{i}^{ \pm}$as nearest-point projections of $v_{i}^{ \pm}$'s to the subtrees $S_{i}, S_{i+1}$, where the projection is taken inside the trees $T_{i}, T_{i+1}$ respectively. Set

$$
y_{i}^{ \pm}:=\Sigma_{i, Y}^{ \pm} \cap X_{w_{i}^{ \pm}} .
$$

See Figure 27.
Since each path $c_{\mathfrak{Z}}$ connecting arbitrary points $y^{ \pm} \in \Sigma_{i}^{ \pm}$is a concatenation of paths in $\Sigma_{i}^{ \pm}$connecting $y^{ \pm}$and $x_{i}^{ \pm}$and of the path $c_{\mathfrak{Q}^{i}}\left(x_{i}^{-}, x_{i}^{+}\right)$, we conclude that whenever $y^{ \pm}$ are both in $Y$, the path $\hat{c}_{\mathfrak{R}}\left(y_{i}^{-}, y_{i}^{+}\right)$passes through the points $y_{i}^{ \pm}$. Since the above paths are uniformly quasigeodesic in the ladders $L_{Y}^{i}$ (Part I.2), we see that the points $y_{i}^{ \pm}$are at uniformly bounded (in terms of $k$ ) distance $R$ from the nearest-point projections (in the ladder $L_{Y}^{i}$ ) of $\Sigma_{i}^{-} \cap Y$ to $\Sigma_{i}^{+} \cap Y$ and vice versa, for all $i=1, \ldots, n-1$. For $i=n$, we have that the point $y_{n}^{-}$within distance $R$ from the projection (in the ladder $L_{Y}^{n}$ ) of $y^{\prime}$ to the section $\Sigma_{n, Y}=\Sigma_{n} \cap Y$. Furthermore, by Part I.2, the paths $\hat{c}\left(y_{i-1}^{+}, y_{i}^{+}\right)$are $\Lambda_{8.22}$-quasigeodesics in $L_{Y}^{i}$. Thus, Theorem 2.59 implies that the alternating concatenation of the paths $\hat{c}_{Q}\left(y_{i}^{-}, y_{i}^{+}\right)$ in $L_{Y}^{i}$ 's and of the paths $c_{\Sigma_{i, Y}}\left(y_{i-1}^{+}, y_{i}^{-}\right)$in $\Sigma_{i, Y}$ 's, is a $\Lambda_{8.3 .3}$-quasigeodesic in $L_{Y}$ connecting $y$ to $y^{\prime}$.

Figure 27. Ladder $L^{i}$ and transition points.

For each vertex $v$ of $\pi\left(\mathfrak{A}^{i}\right)$ we break the geodesic segment $L_{v}^{i} \subset X_{v}$ as a concatenation of two subsegments: $A_{v}^{i}$ (in the carpet $\mathfrak{A}^{i}$ ) and $\beta_{v}^{i}$.

Lemma 8.23. For $w=w_{i}^{+}=\pi\left(y_{i}^{+}\right)$the length of $\beta=\beta_{w}^{i}$ is $\leq C_{8.23}(K)$.
Proof. If the length of $\beta$ is $\leq M_{\bar{K}}$ then we are done. Otherwise, let $J$ be the largest subinterval in $\pi\left(A^{i}\right)$ containing $v$ such that for all vertices $s \in J$ the length of the subinterval $\beta_{s}^{i}$ is $>M_{\bar{K}}$. Since $\beta_{u}^{i}$ has length $\leq M_{\bar{K}}$ and for $v=v_{i}^{+}=\pi\left(x_{i}^{+}\right)$the length of $\beta_{v}^{i}$ is also $\leq M_{\bar{K}}$, uniform $K$-flaring implies that the length of $J$ is $\leq \tau=\tau\left(K, M_{\bar{K}}\right)-2$ and, thus, by Lemma 2.37

$$
\text { length }(\beta) \leq C(k):=a^{\tau}\left(M_{\bar{K}}+b\right)
$$

where $a=L_{0}^{\prime}$ and $b=2 L_{0}^{\prime} K$.
At this point, if we knew that for all $i$ 's the vertices $\pi\left(x_{i}^{+}\right), \pi\left(x_{i+1}^{-}\right)$are separated in $T$ by the subtree $S_{i+1}=\pi\left(\Sigma_{i}^{+}\right)$, then the paths $c_{\Sigma_{i}}\left(x_{i-1}^{+}, x_{i}^{-}\right)$would have to contain the subpaths $c_{\Sigma_{i, Y}}\left(y_{i-1}^{+}, y_{i}^{-}\right)$. This would imply that $\hat{c}$ is a concatenation of the uniform quasigeodesics

$$
c_{\Omega_{Y}}\left(y_{i}^{-}, y_{i}^{+}\right) \star c_{\Sigma_{i, Y}}\left(y_{i}^{+}, y_{i+1}^{-}\right), i=1,2, \ldots,
$$

and then we would be done with the proof of the proposition. However, this (the separation property) need not be the case. What we know, however, from the description of the points $x_{i}^{ \pm}, y_{i}^{ \pm}$, is that in the oriented interval $\pi\left(\mathfrak{H}_{i}\right)$ either

$$
u \leq \pi\left(y_{i}^{+}\right) \leq \pi\left(y_{i}^{-}\right) \leq \pi\left(x_{i}^{+}\right) \leq \pi\left(x_{i}^{-}\right)
$$

or

$$
u \leq \pi\left(y_{i}^{+}\right)=\pi\left(x_{i}^{+}\right) \leq \pi\left(y_{i}^{-}\right) \leq \pi\left(x_{i}^{-}\right)
$$

Moreover, since $\mathfrak{L}, \mathfrak{L}_{Y}$ are ladders, $\pi\left(x_{i}^{+}\right), \pi\left(x_{i+1}^{-}\right)$are separated in $T$ by the subtree $S_{i+1}$ if and only if they are separated in $T$ by the subtree $\pi\left(L_{Y}\right)=\pi(\mathfrak{L}) \cap S$. In particular, for each $i$ either $\pi\left(x_{i}^{ \pm}\right)$are in the same component of $T-\pi\left(L_{Y}\right)$ or $x_{i}^{+}$lies in $Y$. In other words, we find that $y_{i}^{+}$is an $X$-transition point between $y, y^{\prime}$ if either $y_{i}^{+}=x_{i}^{+}$or if $\pi\left(x_{i}^{+}\right)$and $\pi\left(x_{i+1}^{-}\right)$

Figure 28. A clique $C=\left\{x_{i}^{+}, \ldots, x_{j}^{-}, x_{j}^{+}\right\}$.
lie in distinct components of $T-\pi\left(\mathfrak{I}_{Y}\right)$. Thus, we group the points $x_{i}^{ \pm}$into cliques of the form

$$
C=\left\{x_{i}^{+}, x_{i+1}^{-}, x_{i+1}^{+}, \ldots, x_{j}^{+}\right\},
$$

or

$$
C=\left\{x_{i}^{-}, x_{i}^{+}, x_{i+1}^{-}, x_{i+1}^{+}, \ldots, x_{j}^{+}\right\},
$$

etc., consisting of maximal collections of consecutive points in $c$ of the form $x_{l}^{ \pm}$, whose projections to $T$ are not separated by $\pi\left(L_{Y}\right)$. Here it is understood that if one of the two vertices $s, t$ lies in a subtree $T^{\prime} \subset T$, then $s$ and $t$ are separated by this subtree. We will denote a clique as

$$
\left(x_{i}^{ \pm}, \ldots, x_{j}^{ \pm}\right)
$$

where $x_{i}^{ \pm}, x_{j}^{ \pm}$are the first and the last element of a clique $C$, listed in the order of their appearance in the path $c=c\left(x, x^{\prime}\right)$. Elements of a clique have the property that their projections to $T$ followed by the projection to $\pi\left(L_{Y}\right)$ equal to the same vertex $v=v_{C}$, and the corresponding points in $Y$

$$
y_{i}^{ \pm}, \ldots, y_{j}^{ \pm}
$$

all belong to the same vertical geodesic segment $L_{v}, v=v_{C}$. Furthermore, for each $l \in[i, j]$

$$
y_{l}^{+}=y_{l+1}^{-},
$$

since they both belong to $L_{v} \cap \Sigma_{l+1}$.
The first and the last points $x_{i}^{ \pm}, x_{j}^{ \pm}$of a clique $C$ determine points $y_{i}^{ \pm}, y_{j}^{ \pm} \in L_{v} \cap c$ which break $c$ as a concatenation of three subpaths $c_{1} \star c_{2} \star c_{3}$, where $c_{2}=c\left(y_{i}^{ \pm}, y_{j}^{ \pm}\right)$. Thus, each clique defines a decomposition

$$
\hat{c}=\hat{c}_{1} \star \hat{c}_{2} \star \hat{c}_{3},
$$

where $\hat{c}_{2}=\left[y_{i}^{ \pm} y_{j}^{ \pm}\right]_{X_{v}} \subset L_{v}$. The latter path is a concatenation of the subsegments $\left[y_{l}^{-} y_{l}^{+}\right]_{X_{v}} \subset$ $L_{v}$. Each of these subsegments, in turn, is a concatenation of two subsegments: $A_{v}^{l}$ (the narrow end of the carpet $\mathfrak{A}_{Y}^{l} \subset \mathfrak{L}_{Y}^{i}$ ) and a subsegment $\beta_{v}^{l}$ of length $\leq C(k)$, see Lemma 8.23. Since the segment $A_{v}^{l}$ is a uniform quasigeodesic in $L_{Y}^{i}$ (see Lemma 8.21), it follows that $\left[y_{l}^{-} y_{l}^{+}\right]_{X_{v}}$ is a uniform quasigeodesic in $L_{Y}^{i}$.

Thus, the entire path $\hat{c}$ is broken as an alternating concatenation of uniform $Y$-quasigeodesics $\left[y_{l}^{-} y_{l}^{+}\right]_{X_{v}}$ connecting $\Sigma_{l, Y}, \Sigma_{l+1, Y}$ and of (possibly degenerate) horizontal $K$-qi leaves connecting $y_{i}^{+}, y_{i+1}^{-}$inside $\Sigma_{l+1, Y}$. The points $y_{l}^{-}, y_{l}^{+}$, up to a uniformly bounded error, realize the shortest distance in $L_{Y}^{i}$ between $\Sigma_{l, Y}, \Sigma_{l+1, Y}$.

We can now finish the proof of Proposition 8.20 for the slim combing paths $c$ : The path $\hat{c}$ satisfies the conditions of Theorem 2.59 and, hence, is a uniform quasigeodesic in $Y$.

To conclude:
Lemma 8.24. The set of pairs $\left(y, y^{\prime}\right) \in F l_{k}^{Y}\left(X_{u}\right) \times F l_{k}^{Y}\left(X_{u}\right)$ is weakly special. More precisely, there exists $\Lambda_{8.24}(k)$ such that each slim combing path $c$ in $N_{4 \delta_{0}}^{f i b} F l_{k}^{X}\left(X_{u}\right)$ connecting $y$ to $y^{\prime}$ satisfies the property that $\hat{c}$ is a $\Lambda_{8.24}(k)$-quasigeodesic in $Y$.

Proof. Points $y, y^{\prime}$ belong to bottom/top of a $k$-ladder $L(\alpha)$ which is uniformly close to $F l_{k}^{Y}\left(X_{u}\right)$. The combing path $c=c\left(y, y^{\prime}\right)$ in this ladder satisfies the property that $\hat{c}$ is a $\Lambda_{8.24}(k)$-quasigeodesic in $Y$.

Lastly, we prove consistency for arbitrary uniform quasigeodesics $\phi$ connecting points of the given vertex-flow-space, i.e. uniform consistency of points in an arbitrary flow-space $F l_{k}\left(X_{u}\right)$, i.e. prove Proposition 8.20 in full generality.

Since $F l_{k}\left(X_{u}\right)$ is $\delta_{5.17}(k)$-hyperbolic, for each $\Lambda \geq 1$, each $\Lambda$-quasigeodesic $\phi$ in $F l_{k}\left(X_{u}\right)$ connecting $y, y^{\prime}$ is within Hausdorff distance $D(k, \Lambda)$ from a combing path $c=$ $c_{L}\left(y, y^{\prime}\right)$ contained in a ladder $\mathfrak{Z}=\mathfrak{Z}_{X}(\alpha) \subset N_{4 \delta_{0}}^{f i b} F l_{k}\left(X_{u}\right)$, where $y, y^{\prime} \in L_{X}(\alpha)$.

We will be using the notation from the proof of Lemma 8.24. Suppose that $x \in \mathcal{X}$ is a point in $c \subset L_{K}(\alpha), \alpha \subset X_{u}, x \notin L_{Y}$. Then $x$ belongs to one of the subpaths $c\left(y_{i}^{ \pm}, y_{j}^{ \pm}\right)$ determined by a clique $C$ and $\pi(x)$ is a vertex in a subtree of $T$ separated from $\pi\left(L_{Y}\right)$ by the vertex $v=v_{C} \in \pi\left(L_{Y}\right)$. In particular,

$$
d\left(x, X_{S}\right)=d\left(x, X_{v}\right) \geq d(\pi(x), v)
$$

and taking intersection with $L_{v}$ of the canonical $K$-qi section $\Sigma_{x} \subset L_{X}(\alpha)$, we obtain a point $y^{\prime \prime} \in L_{v} \subset L_{Y}$ within distance $K d\left(x, X_{S}\right)$ from $x$. It follows that every point $z \in X_{S}$ within distance $R$ from $x \in c$, lies within distance $(K+1) R$ from a point $\hat{z}=y^{\prime \prime}$ in $\hat{c} \cap L_{v}$. In particular, each intersection point of $\phi$ with $X_{S}$ is within distance $D(k, \Lambda)+(K+1) R$ from a point in $\hat{c} \cap L_{v}$. Furthermore, by the construction, the map $z \mapsto \hat{z}$ is monotonic: If $z_{1}$ appears before $z_{2}$ in $c$, then $\hat{z}_{1}$ appears before $\hat{z}_{2}$ in $\hat{c}$. It now follows that for each $L$-quasigeodesic $\phi$, the path $\hat{\phi}$ is $\hat{\Lambda}$-quasigeodesic in $Y$.

This concludes Part I of the proof of Theorem 8.19.
The next result is an immediate corollary of Proposition 8.20:
Corollary 8.25. Suppose that $p, p^{\prime}$ are point in a vertex-space $X_{v} \subset Y$ such that a $\Lambda$-quasigeodesic $\phi$ in $X$ connecting $p$ to $p^{\prime}$ intersects $X_{v}$ only at its end-points. Then the vertical geodesic $\left[p p^{\prime}\right]_{X_{v}}$ is a $\Lambda^{\prime}=\Lambda_{8.25}^{\prime}(\Lambda)$-quasigeodesic in $Y$.

As another application of Part I, we also obtain a theorem which is essentially due to Mitra, [Mit98]:

Theorem 8.26. There exists a constant $R=R(\Lambda)$ depending only on the tree of spaces $X \rightarrow T$ such that for every vertex $v \in V(T)$ and any pair of points $y, y^{\prime} \in X_{u}$, and any $\Lambda$-quasigeodesic $\phi$ in $X$ with end-points $y, y^{\prime}$, the intersection

$$
X_{u} \cap \phi
$$

is contained in the $R$-neighborhood of the vertical geodesic $\left[y y^{\prime}\right]_{X_{u}}$.
Proof. We will apply Proposition 8.20 to the subtree $S=\{u\}$. By the proposition, each intersection point $z \in X_{u} \cap \phi$ is within distance $D(k, \Lambda)+(K+1) R$ from a point in the geodesic segment $L_{u} \subset\left[y y^{\prime}\right]_{X_{u}}$, where $K=K(k), R=R(k, \Lambda)$ and $k$ can be taken to be uniform, say, $k=K_{0}$.

Corollary 8.27. There exists $R=R_{8.27}(r)$ such that for every vertex $v \in V(T)$ and any pair of points $p, q \in X_{v}$ and geodesics $\alpha=[p q]_{X_{v}}, \beta=[p q]_{X}$, we have

$$
N_{r}\left(X_{v}\right) \cap \beta \subset N_{R}(\alpha)
$$

In particular, if $\alpha^{\prime}=\left[x x^{\prime}\right]_{X_{v}} \subset \alpha=[x y]_{X_{v}}$ and $y \in N_{r}(\beta), \beta=\left[x x^{\prime}\right]_{X}$, then $d\left(y, x^{\prime}\right) \leq R$. (See Figure 29.)

Figure 29
As another corollary, we obtain Mitra's theorem on the existence of CT-maps (Theorem 8.10):

Proof of Theorem 8.10. We will use Mitra's Criterion for the inclusion map $f: X_{u} \rightarrow$ $X$ (Proposition 8.7). We prove that $f$ satisfies the assumption of Proposition 8.7 by arguing the contrapositive.

Fix a base-point $y \in Y$ and consider a sequence of vertical geodesics $\alpha_{n}=\left[x_{n} x_{n}^{\prime}\right]_{X_{u}}$. Assume that each $X$-geodesic $\beta_{n}=\left[x_{n} x_{n}^{\prime}\right]_{X}$ has nonempty intersection with the $r$-ball $B(y, r) \subset X$ for some fixed $r$. After replacing $\beta_{n}$ 's with uniform quasigeodesics $\phi_{n}$ in $X$, we ensure that $y \in \phi_{n}$ for all $n$. Therefore, $y \in \hat{\phi}_{n}$ as well. Since the Hausdorff distance between $\hat{\phi}_{n}$ and $\alpha_{n}$ is uniformly bounded, the minimal distances between $y$ and $\alpha_{n}$ 's are uniformly bounded too. Thus, the assumption of Proposition 8.7 is satisfied and, hence, the inclusion map $f: X_{u} \rightarrow X$ admits a CT-extension.

In Part II of the proof of Theorem 8.19 we will need several technical results regarding projections to $X$-geodesics connecting points in $X_{u}, u \in V(S)$. These results occupy the rest of this section. We consider a $(K, D, E)$-ladder $\mathfrak{L}=\mathfrak{Q}_{X}(\alpha)$, where $p, p^{\prime} \in X_{u}$ and $\alpha=\left[p p^{\prime}\right]_{X_{u}}$. We will be investigating the nearest-point projection (taken in $X$ ) of points $y \in \alpha=\left[p p^{\prime}\right]_{X_{u}}$ to a $\Lambda$-quasigeodesic geodesic $\phi$ in $X$ containing a detour path $\zeta=\phi\left(p, p^{\prime}\right)$ connecting the points $p, p^{\prime}$. Most of the discussion deals with the case $\phi=\zeta$. Since the path $\zeta$ is uniformly Hausdorff-close to the combing path $c=c_{X}\left(p, p^{\prime}\right)$, in order to understand the projection of $y$ to $\zeta$, it suffices to analyze the projection of $y$ to $c$ (see Corollary 1.105).

Lemma 8.28. Suppose that $p, p^{\prime}$ belong to a common vertex-space $X_{u}$. Let $\left\{\alpha_{i}\right\}$ be a vertical subdivision of $\alpha=\left[p p^{\prime}\right]_{X_{u}}$. Then:

1. For each $y \in \alpha_{i}=\left[p_{i} p_{i+1}\right]_{X_{u}}$ the projection $\bar{y}=P_{X, c}(y) \in c=c_{X}\left(p, p^{\prime}\right)$ is uniformly close to a point $\bar{y}^{\prime}$ in the subladder $L^{i}=L_{K}\left(\alpha_{i}\right)$ determined by $\alpha_{i}$ :

$$
d_{X}\left(\bar{y}, \bar{y}^{\prime}\right) \leq C=C_{8.28}(K, D, E, \Lambda)
$$

2. The point $\bar{y}^{\prime}$ can be chosen to lie in the carpet $A^{i}=A\left(\alpha_{i}^{\prime}\right) \subset L^{i}$, where $\alpha_{i}^{\prime} \subset \alpha_{i}$ is as in Proposition 4.11.
3. The point $\bar{y}^{\prime} \in A^{i}$ can be chosen so that $y, \bar{y}^{\prime}$ are connected by a (canonical in $\left.A^{i} \subset L^{i}\right) K$-qi leaf contained in $A^{i}$.

Proof. 1. Connect $y$ to a point $z \in c \cap L^{i}$ by a geodesic $[y z]_{X}$. Since $L^{i}$ is $\lambda$-quasiconvex in $X,[y z]_{X}$ lies in the $\lambda$-neighborhood of $L^{i}$. On the other hand, by Lemma $1.102,[y z]_{X}$, as any geodesic connecting $y$ to $c$, has to pass uniformly close to $\bar{y}$, namely, within distance $\lambda^{\prime}+3 \delta_{X}$, where $\lambda^{\prime}$ is the quasiconvexity constant (in $X$ ) of the path $c$. It follows that $\bar{y}$ lies distance $C=\lambda+\lambda^{\prime}+3 \delta_{X}$ from a point $\bar{y}^{\prime} \in L^{i}$.
2. By Part (1), $\bar{y} \in c$ lies within distance $C$ from a point $\bar{y}^{\prime} \in L^{i}$. If $\bar{y} \notin L^{i}$, take the smallest subpath in $c$ connecting $\bar{y}$ to a point $z \in L^{i}$. Then (by the construction of the path $c$ ) the point $z$ realizes (up to a uniform additive error) the minimal distance from $\bar{y}$ to $L^{i}$. Hence, by replacing $C$ with another uniform constant $C^{\prime}$, we can assume that $\bar{y}^{\prime} \in c_{i}:=c \cap L^{i}, d_{X}\left(\bar{y}, \bar{y}^{\prime}\right) \leq C^{\prime}$.

Figure 30. Path $c_{i}$

Note that $c_{i}$ is the concatenation

$$
c\left(x_{i-1}^{+}, x_{i}^{-}\right) \star c\left(x_{i}^{-}, x_{i}^{+}\right) \star c\left(x_{i}^{+}, x_{i+1}^{-}\right)
$$

see Figure 30. The middle subpath lies in $A^{i}$ (except for a vertical subpath of length $\leq M_{\bar{K}}$ ); therefore, there are just two cases we have to consider:
(a) $\bar{y}^{\prime} \in c\left(x_{i-1}^{+}, x_{i}^{-}\right) \backslash A^{i}$. Then, by the description of combing paths in $L^{i}$ (see Section 7.1, Step I.2), the path $c\left(\bar{y}^{\prime}, y\right)$ contains a subpath contained in $\operatorname{bot}\left(L^{i}\right) \cap c\left(x_{i-1}^{+}, x_{i}^{-}\right) \subset c_{i} \subset c$ and connecting $\bar{y}^{\prime}$ to a point $A^{i}$. Since $\bar{y}^{\prime}$ is uniformly close to the projection of $y$ to $c$ (and since $c\left(\bar{y}^{\prime}, y\right)$ is uniformly quasigeodesic), the length of that subpath of $c\left(\bar{y}^{\prime}, y\right)$ is uniformly bounded and, hence, $\bar{y}^{\prime}$ is uniformly close to a point in $c_{i} \cap A^{i}$, as required by the second statement of the lemma.
(b) $\bar{y}^{\prime} \in c\left(x_{i}^{+}, x_{i+1}^{-}\right) \backslash A^{i}$, see Figure 31. The proof is similar to Case (a): The path $c\left(\bar{y}^{\prime}, y\right)$ starts with a subpath $c_{\bar{y}^{\prime}} \subset L^{i}$ connecting $\bar{y}^{\prime}$ to $A^{i}$ (again, see Section 7.1, Step I.2). Since the length of the part of $c_{\bar{y}^{\prime}}$ contained in $c_{i}$ has to be uniformly bounded (as in Case (a)), by changing the location of $\bar{y}^{\prime} \in c_{i} \cap \operatorname{top}\left(L^{i}\right)$ by a uniformly bounded amount, we can assume that for

$$
b=\operatorname{center}\left(\Delta u \pi\left(x_{i}^{+}\right) \pi\left(x_{i+1}^{-}\right)\right)=\operatorname{center}\left(\Delta u w_{i} \pi\left(x_{i+1}^{-}\right)\right),
$$

the vertex $v=\pi(\bar{y})$ lies in the interval

$$
\llbracket b, \pi\left(x_{i}^{+}\right) \rrbracket \subset \llbracket u, \pi\left(x_{i}^{+}\right) \rrbracket,
$$

where $\pi\left(A^{i}\right)=\llbracket u, w_{i} \rrbracket$. Therefore, by Lemma 4.12(2), the vertical distance from $\bar{y}^{\prime}$ to the top of $A_{v}^{i}$ is bounded by $R_{4.12}(K)$. This concludes the proof of (2).
3. Thus, we assume that $\bar{y}^{\prime} \in c_{i} \cap A^{i}$. If $y \in \alpha_{i} \backslash \alpha_{i}^{\prime}$, then $\bar{y}^{\prime} \in \operatorname{top}\left(A^{i}\right)$ and $c\left(\bar{y}^{\prime}, x_{i}^{+}\right)$has uniformly bounded length and, without loss of generality, $c\left(\bar{y}^{\prime}, x_{i}^{+}\right)$is a vertical segment of length $\leq M_{\bar{K}}$. The canonical $K$-section $\Sigma_{y} \subset L^{i}$ crosses the vertical interval $c\left(\bar{y}^{\prime}, x_{i}^{+}\right)$at some point $\bar{y}^{\prime \prime}$ and $d\left(\bar{y}^{\prime}, \bar{y}^{\prime \prime}\right) \leq M_{\bar{K}}$. Thus, from now on, we assume that $y \in \alpha_{i}^{\prime} \subset A^{i}$.

The intersection $c_{i} \cap A^{i}$ consists of a path in top $\left(A^{i}\right)$, the narrow end of $A^{i}$ (which has length $\leq M_{\bar{K}}$ ) and of a path contained in $\operatorname{bot}\left(A^{i}\right)$ which equals

$$
c\left(x_{i-1}^{+}, x_{i}^{-}\right) \cap \operatorname{bot}\left(A^{i}\right)
$$

Since every point in the narrow end of $A^{i}$ is connected to each point of $\alpha_{i}^{\prime}$ by a $K$-qi section, we have two cases to consider:
(a)

$$
\bar{y}^{\prime} \in c\left(x_{i-1}^{+}, x_{i}^{-}\right) \cap \operatorname{bot}\left(A^{i}\right) .
$$

By the definition of the path

$$
c\left(\bar{y}^{\prime}, y\right)
$$

it is a concatenation of a horizontal subpath contained in $c\left(x_{i-1}^{+}, x_{i}^{-}\right) \cap \operatorname{bot}\left(A^{i}\right)$, followed by a vertical path of length $\leq M_{\bar{K}}$ and, then by a $K$-qi leaf

$$
\gamma_{\bar{y}^{\prime \prime}, y} \subset A^{i}
$$

connecting $\bar{y}^{\prime \prime}$ to $y$. (Note that $\bar{y}^{\prime \prime}$ does not, in general, lie in $c$, it is just within distance $\leq M_{\bar{K}}$ from a point in $c$.) The first horizontal subpath is entirely contained in $c_{i} \subset c$, hence, has to have uniformly bounded length. Thus, $\bar{y}^{\prime}$ is uniformly close to the point $\bar{y}^{\prime \prime} \in A^{i}$ connected to $y$ by a $K$-qi section. This concludes the proof in case (a).
(b)

$$
\bar{y}^{\prime} \in c\left(x_{i-1}^{+}, x_{i}^{-}\right) \cap \operatorname{top}\left(A^{i}\right)
$$

Figure 31. Path $c_{i}$
This case is similar to (a): The path $c\left(\bar{y}^{\prime}, y\right)$ is a concatenation of a subpath contained in $c$, followed by a short vertical subpath and, then, by a $K$-qi leaf connecting a point $\bar{y}^{\prime \prime} \in A^{i}$ to $y$. The first two subpaths are uniformly short, hence, we are done.

Corollary 8.29. If $d(\bar{y}, p) \leq R$, then

$$
d_{X}(y, p) \leq R^{\prime}=R_{8.29}^{\prime}(R, K, C)
$$

where $C=C_{8.28}$.
Proof. Taking $\bar{y}^{\prime}$ is as in Part (3) of Lemma 8.28, we obtain

$$
d_{T}\left(u, \pi\left(\bar{y}^{\prime}\right)\right) \leq d_{X}\left(p, \bar{y}^{\prime}\right) \leq R+C
$$

Since $y, \bar{y}^{\prime}$ are connected by a $K$-qi leaf over the interval $\llbracket u, \pi\left(\bar{y}^{\prime}\right) \rrbracket$,

$$
d_{X}\left(y, \bar{y}^{\prime}\right) \leq K d_{T}\left(u, \pi\left(\bar{y}^{\prime}\right)\right) \leq K(R+C)
$$

which, in turn, implies the inequality $d_{X}(y, p) \leq(K+1)(R+C)$.
Lastly, we turn to the projection of $y \in\left[p p^{\prime}\right]_{X_{u}}$ to a $\Lambda$-quasigeodesic $\phi$ (with end-points in $Y$ ) containing $\zeta=\phi\left(p, p^{\prime}\right)$ as a detour subarc:

Lemma 8.30.

$$
d\left(P_{X, \phi}(y), \zeta\right) \leq D_{8.30}=D_{8.30}(K, D, E, \Lambda)
$$

Proof. The result is an application of Corollaries 1.107 and 8.29. The subsets $U=$ $\phi, V=\zeta$ are $D_{1.53}\left(\delta_{X}, \Lambda\right)$-quasiconvex in $X$. Assume that $\bar{y}:=P_{X, \phi}(y)$ is not in the arc $\zeta$. In view of the Morse Lemma (Lemma 1.53), for each $z \in \zeta$ the geodesic $[\bar{y} z]_{X}$ passes within
distance $D_{1.53}\left(\delta_{X}, \Lambda\right)$ from $p$ or from $p^{\prime}$ (depending which component of $\phi \backslash \zeta$ the point $\bar{y}$ belongs to). We will assume that it is $p$ rather than $p^{\prime}$. Therefore, by Lemma 1.102(i), the projection of $\bar{y}$ is within distance $2 D_{1.53}\left(\delta_{X}, \Lambda\right)$ from $p$ or from $p^{\prime}$. But, according to Corollary 1.107,

$$
d_{X}\left(P_{U, V} \circ P_{X, U}(y), P_{X, V}(y)\right) \leq C_{1.107}\left(\delta_{X}, D_{1.53}\left(\delta_{X}, \Lambda\right)\right)
$$

Hence,

$$
d_{X}\left(P_{V}(y), p\right) \leq R:=C_{1.107}\left(\delta_{X}, D_{1.53}\left(\delta_{X}, \Lambda\right)\right)+2 D_{1.53}\left(\delta_{X}, \Lambda\right)
$$

Applying Corollary 8.29, we get

$$
d_{X}(y, p) \leq R_{8.29}^{\prime}(D)
$$

and, therefore, $d_{X}(\bar{y}, p) \leq D_{8.30}:=2 R_{8.29}^{\prime}(R)$.
Corollary 8.31.

$$
d\left(P_{X, \phi}(y), P_{X, \zeta}(y)\right) \leq D_{8.31}(K, D, E, \Lambda)
$$

Proof. If $P_{X, \phi}(y) \in \zeta$ then $P_{X, \phi}(y)=P_{X, \zeta}(y)$. Assume, therefore, that $P_{X, \phi}(y) \notin \zeta$. According to lemma, $P_{X, \phi}(y)$ is within distance $D_{8.31}$ from a point $q \in \zeta$. Therefore,

$$
d_{X}(y, q) \leq d(y, \zeta)+D_{8.31}
$$

By Corollary 1.104,

$$
d_{X}\left(q, P_{X, \zeta}(y)\right) \leq D_{8.31}+2 \lambda+4 \delta_{X}
$$

where $\lambda=D_{1.53}\left(\delta_{X}, \Lambda\right)$ is the quasiconvexity constant of $\zeta \subset X$.

### 8.4. Part II: Consistency in semispecial flow-spaces

8.4.1. Part II.4: Projections in special flow-spaces. In this part of the proof (which is the most difficult part of Section 8.4) we are assuming that vertices $u, v \in V(S)$ define a $K$-special interval $J=\llbracket u, v \rrbracket \subset S$. In order to simplify the notation we set

$$
F_{w}^{X}=F l_{K}^{X}\left(X_{w}\right), \quad F_{w}^{Y}=F l_{K}^{Y}\left(X_{w}\right)
$$

for vertices $w \in V(S)$. Observe that $F_{v}^{X} \cap X_{u} \neq \emptyset \Longleftrightarrow F_{v}^{Y} \cap X_{u} \neq \emptyset$ and $F_{u}^{X} \cap X_{v} \neq$ $\emptyset \Longleftrightarrow F_{u}^{Y} \cap X_{v} \neq \emptyset$, i.e. it does not matter in what space ( $X$ or $Y$ ) our interval $J$ is special. In the proofs below, it does not matter which of the above intersections is nonempty. In this section we will relate the $X$-projection $\bar{x}$ of $x \in F_{v}^{Y}$ to $F_{u}^{X}$ and the $Y$-projection $\overline{\bar{x}}$ of $x$ to $F_{u}^{Y}$. At the same time, we will establish uniform consistency of some classes of pairs $\left(x, x^{\prime}\right) \in F_{v}^{Y} \times F_{u}^{Y}$. These results will be the key for proving uniform consistency of pairs of points in semispecial flow-spaces, which will be done in the next section. (This will apply, of course, to points in special flow-spaces as well.) After altering $\bar{x}$ and $\overline{\bar{x}}$ by uniformly bounded distance, we can assume that these points belong to vertex-spaces of $X$ and $Y$ respectively.

Recall (see Lemma 1.102) that the concatenation

$$
\phi=[x \bar{x}]_{X} \star\left[\bar{x} x^{\prime}\right]_{X}
$$

is a $\Lambda$-quasigeodesic in $X$, where $\Lambda$ depends only on the quasiconvexity constant $\lambda_{X}$ of $F_{u}^{X}$ and the hyperbolicity constant of $X$ (i.e. only on the parameters of $\mathfrak{X}$ and $K$ ). If $\bar{x} \notin Y$, we let $\zeta=\phi\left(\hat{x}, \hat{x}^{\prime}\right)$ denote the detour subpath in $\phi$ containing $\bar{x}$ and connecting points $\hat{x}, \hat{x}^{\prime}$ which belong to the same vertex-space $X_{t} \subset Y$. In the case $\bar{x} \in Y \cap X_{t}$, we declare $\zeta$ to be degenerate, equal to the singleton $\{\bar{x}\}$, and, accordingly, set

$$
\hat{x}=\hat{x}^{\prime}=\bar{x}
$$

Remark 8.32. Even if $\bar{x}$ is far away from $Y$, the points $\hat{x}, \hat{x}^{\prime}$ depend quite a bit on the quasigeodesic $\phi$ (i.e. on the choice of geodesics $\left.[x \bar{x}]_{X},\left[\bar{x} x^{\prime}\right]_{X}\right)$ connecting $x, x^{\prime}$. The notation $\hat{x}, \hat{x}^{\prime}$, therefore, is ambiguous and, in truth, should contain the symbol $\phi$, which we omit for the ease of the notation.

Figure 32. Two projections.
The key result of Part II. 4 is:
Lemma 8.33. The point $\overline{\bar{x}}$ lies within distance $R_{8.33}(K, \Lambda)$ from a point of the segment $\hat{\zeta}=\left[\hat{x} \hat{x}^{\prime}\right]_{X_{t}}$, no matter what $x^{\prime}$ and $\phi$ are.

Proof. Consider the subpath $\phi^{\prime}=\phi\left(x, \hat{x}^{\prime}\right)$ connecting $x$ to $\hat{x}^{\prime}$ and passing through $\hat{x}$ :

$$
\phi^{\prime}=\phi_{1} \star \zeta
$$

(The subpath $\phi_{1}$ is geodesic since it is contained in $[x \bar{x}]_{X}$.) See Figure 32. Then

$$
\hat{\phi}^{\prime}=\hat{\phi}_{1} \star \hat{\zeta} .
$$

We already know (by Proposition 8.20 and Corollary 8.25) that $\hat{\phi}_{1}$ and $\hat{\zeta}$ are uniform $Y$ quasigeodesics, but we do not yet know that their concatenation is, since uniform consistency of the pairs $\left(x, \hat{x}^{\prime}\right)$ is not yet known, except in some special cases. We do know, however, the uniform consistency of the pair $(x, \overline{\bar{x}})$ : Since $F_{v}^{Y} \cap F_{u}^{Y} \neq \emptyset$, Lemma 1.127 implies that the point $\overline{\bar{x}}$ lies in the $2 \lambda_{Y}+3 \delta_{Y}$-neighborhood of $F_{v}^{Y}$, where $\lambda_{Y}$ is the quasiconvexity constant of flow-spaces $F l_{w}^{Y} \subset Y$. Therefore, the uniform consistency of the pairs ( $x, \overline{\bar{x}}$ ) follows from Proposition 8.20.

Since the geodesic $\left[x \hat{x}^{\prime}\right]_{Y}$ passes uniformly close to the projection $\overline{\bar{x}}$ of $x$ to $F_{u}^{Y}$, by the $\delta_{Y}$-slimness of the geodesic triangle

$$
\Delta_{Y} x \hat{x} \hat{x}^{\prime} \subset Y
$$

either $\hat{\phi}_{1}$ or $\hat{\zeta}$ passes within the distance $R=R(K)$ from $\overline{\bar{x}}$. If it is $\hat{\zeta}$, we are done. Consider, therefore, the case that $\hat{\phi}_{1}$ passes within distance $R$ from $\overline{\bar{x}}$. The path $\hat{\phi}_{1}$ is a concatenation of subarcs $\phi_{1} \cap Y$ with vertical geodesics $\hat{\zeta}_{i}$, where each $\zeta_{i}$ is a detour subarc in $\phi_{1}$.

Suppose first that $\phi_{1} \cap Y$ passes within distance $R$ from $\overline{\bar{x}} \in F_{u}^{Y}$. Since $\phi_{1}$ is geodesic in $X$ and $\bar{x}$ is the nearest-point projection of $x$ to $F_{u}^{X}$, we obtain:

$$
d(\overline{\bar{x}}, \bar{x}) \leq 2 R .
$$

In particular, $d\left(\bar{x}, X_{t}\right) \leq 2 R$ as well (since $[\bar{x} \overline{\bar{x}}]_{X}$ has to cross $X_{t}$ ). By Corollary 8.27, the intersection

$$
B(\bar{x}, 2 R) \cap X_{t}
$$

is uniformly close to a subset of $\hat{\zeta}$ and, hence, we are done, in this case as well.
It remains to analyze the harder case when for one of the detour subarcs $\zeta_{1} \subset \phi_{1}$, the path $\hat{\zeta}_{1}$ passes within distance $R$ from $\overline{\bar{x}}$. Let $X_{s}$ denote the vertex-space of $Y$ containing the end-points $p, p^{\prime}$ of $\zeta_{1}$ and $y \in \hat{\zeta}_{1} \subset X_{s}$ a point within distance $R$ from $\overline{\bar{x}}$. Let $\bar{y}$ denote the nearest-point projection of $y$ to $\zeta_{1}$.

The point $\bar{y}$ lies within distance $D_{8.30}$ from the projection of $y$ to $\phi_{1}$ since the latter contains $\zeta_{1}$, see Lemma 8.30. The concatenation $\psi=\psi_{1} \star[\bar{y} y]_{X}$ (where $\psi_{1}$ is the subpath of $\phi_{1}$ between $x$ and $\bar{y}$ ) is a uniform quasigeodesic in $X$ connecting $x$ to the point $y$ within distance $R$ from $\overline{\bar{x}}$.

Since $F_{v}^{X}$ is $\lambda_{X}$-quasiconvex in $X,[y \overline{\bar{x}}]_{X}$ has length $\leq R$ and $\psi$ is a uniform quasigeodesic in $X$, the path $\psi^{\prime}=\psi \star[y \overline{\bar{x}}]_{X}$ (connecting $x$ to $\overline{\bar{x}}$ ) lies within a uniform neighborhood of $F_{v}^{X}$. Since $\overline{\bar{x}}$ is in the $2 \lambda_{Y}+3 \delta_{Y}$-neighborhood of $F_{v}^{Y} \subset F_{v}^{X}$, by Lemma 1.102(i) the path $\psi^{\prime}$ (connecting $x \in F_{v}^{X}$ to $\overline{\bar{x}}$ which is uniformly close to $F_{v}^{X}$ ) passes, at some point $z \in \psi^{\prime}$, uniformly close to $\bar{x}$.

Where could this point $z$ be? If $z$ lies in $\psi_{1}$, then, since $\bar{y}$ is between $z$ and $\bar{x}$ in $\phi$, the length of the entire subpath $\phi^{\prime \prime}$ of $\phi$ between $\bar{x}$ and $\bar{y}$ is uniformly bounded. Similarly, if $z$ lies in $[y \overline{\bar{x}}]_{X}$ then, since the concatenation of $\phi^{\prime \prime}$ with $[\bar{y} y]_{X}$ is also a uniform quasigeodesic, the length of $\phi^{\prime \prime}$ is uniformly bounded as well. The path $\phi^{\prime \prime}$ includes a subpath (contained in $\zeta_{1}$ ) between $\bar{y}$ and $p^{\prime}$, and we conclude that the distance between $\bar{y}$ and $p^{\prime}$ is uniformly bounded by some constant $D$. Therefore, by Corollary 8.29 , the distance between $y$ and $p^{\prime}$ is $\leq D^{\prime}=D_{8.29}^{\prime}(D)$, implying a uniform upper bound on the distance from $\overline{\bar{x}}$ to $\hat{x} \in \phi^{\prime \prime}$. Therefore, in this case again, we see that $\overline{\bar{x}}$ is uniformly close to a point (namely, $\hat{x}$ ) in the segment

$$
\hat{\zeta}=\left[\hat{x} \hat{x}^{\prime}\right]_{X_{t}} .
$$

Of course, in this case the distance between $\overline{\bar{x}}$ and $\bar{x}$ is also uniformly bounded as well.
In fact, we can pin down the location of a point $y \in \hat{\zeta}$ within distance $R_{8.33}(K)$ from $\overline{\bar{x}}$ a bit further. Namely, the set of points $\hat{x}^{\prime}$ in the lemma is precisely the $4 \delta_{0}$-quasiconvex subset $Q_{t} \subset X_{t}$ equal to the intersection

$$
X_{t} \cap F l_{u}^{X}
$$

Since $\overline{\bar{x}}$ is uniformly close to a point in each of the geodesics $\left[\hat{x} \hat{x}^{\prime}\right]_{X_{t}}, \hat{x}^{\prime} \in Q_{t}$, by applying Corollary 1.106 we conclude that $\overline{\bar{x}}$ is uniformly close to a point in the geodesic segment $[\hat{x} y]_{X_{t}}$, where $y$ is the projection (taken in $X_{t}$ ) of $\hat{x}$ to $Q_{t}$.

At the same time, since $\overline{\bar{x}}$ belongs to $F_{u}^{Y}$, y lies in the intersection of $X_{t}$ with the $R_{8.33}(K)$-neighborhood of $F_{u}^{Y}$ (the neighborhood is taken in $X$ ). Thus, by Lemma 3.29, the point $y$ lies in

$$
N_{D}^{f i b}\left(Q_{t}\right) \subset X_{t}
$$

where $D=D_{3.29}(R, K)$. We conclude:
Corollary 8.34. The point $\overline{\bar{x}}$ is uniformly close to the projection $\tilde{x}$ (taken in $X_{t}$ ) of $\hat{x}$ to $Q_{t}=X_{t} \cap F l_{K}^{X}\left(X_{u}\right)$.

Figure 33. Location of $\overline{\bar{x}}$.
Note that, while the point $\hat{x}$ depends heavily on the choice of the path $\phi$ connecting $x, x^{\prime} \in F_{u}^{Y}$, the point $\tilde{x}$ is canonical (up to a uniform error, depending only on $K$ ).

Another observation relating the position of the points $\overline{\bar{x}}$ and $\bar{x}$ is that, setting $y:=\tilde{x}$, if $\bar{y}$ denotes the $X$-projection of $y$ to the detour $\operatorname{arc} \zeta$ (connecting $\hat{x}$ and $\hat{x}^{\prime}$ ), then $\bar{x}$ is uniformly close to a point in the subarc $\zeta(\hat{x}, \bar{y}) \subset \zeta$ : Otherwise, as in the proof of Lemma 8.33, the concatenation $[y \bar{y}]_{X} \star \zeta(\bar{y}, \hat{x})$ is a uniform $X$-quasigeodesic. Therefore, it has to pass uniformly close to the point $\bar{x}$. At the same time, the concatenation $[y \bar{y}]_{X} \star \zeta\left(\bar{y}, \hat{x}^{\prime}\right)$ is also a uniform $X$-quasigeodesic. Thus, $\bar{x}$ would have to be within uniformly bounded distance from both $[y \bar{y}]_{X}$ and $\zeta\left(\bar{y}, \hat{x}^{\prime}\right)$, which means that $\bar{x}$ is uniformly close to $\bar{y}$. We, therefore, proved (see Figure 34):

Lemma 8.35. $d_{X}(\bar{x}, \zeta(\hat{x}, \bar{y})) \leq C_{8.35}(K)$.

Corollary 8.36. If $d_{X}(\bar{x}, Y) \leq r$, then $d_{X}(\bar{x}, \overline{\bar{x}}) \leq \bar{r}=\bar{r}_{8.36}(K, r)$.
Proof. Choose $x^{\prime}=y=\tilde{x}$ as above. As before, the concatenation $[x \bar{x}]_{X} \star[\bar{x} y]_{X}$ is a $\Lambda$-quasigeodesic in $X$ for $\Lambda$ depending only on $K$. Take a point $p \in X_{t}$ within distance $r$ from $\bar{x}$. Then, according to Lemma 3.29,

$$
d\left(p, F_{u} \cap X_{t}\right) \leq D_{3.29}(r, K)
$$

Figure 34. Location of $\bar{x}$ in the detour path.

At the same time, by Corollary 8.27 , the point $p$ can be chosen to lie in the $R_{8.27}(r)$ neighborhood of the segment $[\hat{x} y]_{X_{t}}$. Since $y=\tilde{x}$ was the projection of $\hat{x}$ to $F_{u} \cap X_{t}$ (taken in $X_{t}$ ), it follows that the distance from $p$ to $y$ is uniformly bounded.

We are now ready to prove (using the notation introduced above, with the point $y:=\tilde{x}$ uniformly close to $\overline{\bar{x}}$ ):

Lemma 8.37. For all $K$-special intervals $J=\llbracket u, v \rrbracket$ in $S$, and all pairs $\left(x, x^{\prime}\right) \in F_{v}^{Y} \times$ $F_{u}^{Y}$ :

1. The points $\hat{x}$ are uniform transition points between $x, \hat{x}^{\prime}$.
2. The pairs ( $x, \hat{x}^{\prime}$ ) are uniformly consistent.

Proof. 1. By the construction, the point $\hat{x}$ belongs to the $\Lambda=\Lambda(K)$-quasigeodesic $\phi=[x \bar{x}]_{X} \star\left[\bar{x} \hat{x}^{\prime}\right]_{X}$ connecting $x$ to $\hat{x}^{\prime}$, implying that $\hat{x}$ is a uniform $X$-transition point between $x, \hat{x}^{\prime}$. To prove the $Y$-transition property, note that the concatenation

$$
[x y]_{Y} \star\left[y \hat{x}^{\prime}\right]_{X_{t}}
$$

is a uniform $Y$-quasigeodesic (since $y$ is uniformly close to the nearest-point projection in $Y$ of $x$ to $F_{u}^{Y}$ and $\left[y \hat{x}^{\prime}\right]_{X_{t}}$ is a uniform quasigeodesic in $F_{u}^{Y}$ ). Thus, we only have to prove that $[x y]_{Y}$ passes uniformly close to $\hat{x}$. As we noted earlier, the pairs $(x, y)$ are uniformly consistent (since $x \in F_{v}^{Y}$ and $y$ lies in a uniform neighborhood of $F_{v}^{Y}$ ). The concatenation

$$
\psi=[y \bar{y}]_{X} \star[\bar{y} x]_{X}
$$

is a uniform quasigeodesic in $X$. The path $\hat{\psi}=[y \hat{x}]_{X_{t}} \star \hat{\psi}(\hat{x}, x)$ passes through $\hat{x}$ and is a uniform $Y$-quasigeodesic (by the uniform consistency of the pair $(x, y)$ ). The same, therefore, holds for the geodesic $[y x]_{Y}$. This implies that $\hat{x}$ is a uniform transition point between $x$ and $\hat{x}^{\prime}$.
2. The pairs $(x, \hat{x}),\left(\hat{x}, \hat{x}^{\prime}\right)$ are uniformly consistent according to Proposition 8.20, because the first is in $F_{v}^{Y} \times F_{v}^{Y}$ and the second is in $X_{t}^{2}$. Since $\hat{x}$ is a uniform transition point between $x, \hat{x}^{\prime}$ according to Part 1 , the pairs ( $x, \hat{x}^{\prime}$ ) are uniformly consistent (see Lemma 8.17).

This concludes Part II. 4 of the proof of Theorem 8.19.
8.4.2. Part II.5: Pairs in semispecial flow-spaces. Consider a $K$-semispecial interval $J=J_{1} \cup J_{2}$ which is a union of two $K$-special intervals $J_{1}, J_{2}$ meeting only at a common end-point $w$. We will prove uniform consistency of pairs of points in $F l_{K}^{Y}\left(X_{J}\right)$ : This will also apply to the case of special intervals $J$ since would arbitrarily subdivide it into two subintervals. Observe that it suffices to prove uniform consistency of pairs of points $x_{i} \in F_{v_{i}}^{Y}=F l_{K}^{Y}\left(X_{v_{i}}\right), v_{i} \in V\left(J_{i}\right), i=1,2$. Indeed, if $v_{i}, i=1,2$ are both in, say, $J_{1}$, then we subdivide the interval $J_{1}$ further, to subintervals $J_{1}^{\prime}, J_{1}^{\prime \prime}$ containing $v_{1}, v_{2}$ respectively.

Proposition 8.38. Each pair $\left(x_{1}, x_{2}\right)$ as above is $\theta_{8.38, K}$-consistent.
Proof. For $i=1,2$ consider the point

$$
\bar{x}_{i}=P_{X, F_{w}^{x}}\left(x_{i}\right),
$$

which is the nearest-point projection of $x_{i}($ taken in $X)$ to the flow-space $F_{w}^{X}=F l_{K}^{X}\left(X_{w}\right)$.

Figure 35. Path $\phi$ from $x_{1}$ to $x_{2}$.

Lemma 8.39. The points $\bar{x}_{1}, \bar{x}_{2}$ cannot lie in the same component of $X-Y$.
Proof. Assume that both $\bar{x}_{1}, \bar{x}_{2}$ belong to $X-Y$; in particular, $\pi\left(\bar{x}_{i}\right) \neq w, i=1,2$. Then the vertex $w$ cannot separate $w_{i}=\pi\left(\bar{x}_{i}\right)$ from $v_{i}, i=1,2$ : If $w$ were to separate these vertices, then the geodesic $\left[x_{i} \bar{x}_{i}\right]_{X}$ would cross into $X_{w}$ before reaching $\bar{x}_{i}$ and, thus, $\bar{x}_{i}$ would not be a nearest point to $x_{i}$ in $F_{w}^{X}$. In particular, the geodesics $\llbracket v_{i}, w_{i} \rrbracket$ lie in distinct components of $T-\{w\}$ and, hence, $w_{1}, w_{2}$ are separated by $w \in S$. Thus, $\bar{x}_{1}, \bar{x}_{2}$ cannot lie in the same connected component of $X-Y$.

As we proved in Section 2.6.2, the concatenations

$$
\phi=\left[x_{1} \bar{x}_{1}\right]_{X} \star\left[\bar{x}_{1} \bar{x}_{2}\right]_{X} \star\left[\bar{x}_{2} x_{2}\right]_{X},
$$

Figure 36. Transition points on the path from $x_{1}$ to $x_{2}$.
are $\Lambda$-quasigeodesics, where $\Lambda=\Lambda(K)$. As in the previous section, we consider detour subpaths $\zeta_{i} \subset \phi$ containing $\bar{x}_{i}$,

$$
\zeta_{i}=\phi\left(\hat{x}_{i}, \hat{x}_{i}^{\prime}\right),
$$

where $\hat{x}_{i}, \hat{x}_{i}^{\prime} \in X_{t_{i}}, i=1,2$. (See Figure 36.) By Lemma 8.39, these detour subpaths have to be disjoint, except, possibly at their end-points. The points $\hat{x}_{i}^{\prime}$ belong to the middle portion $\left[\bar{x}_{1} \bar{x}_{2}\right]_{X}$ of $\phi$. We mark points

$$
y_{i} \in\left[\hat{x}_{i} \hat{x}_{i}^{\prime}\right]_{x_{t}}, i=1,2
$$

which are uniformly close to the projections $\overline{\bar{x}}_{i}=P_{Y, F_{w}^{\gamma}}\left(x_{i}\right)$, see Lemma 8.33.
Lemma 8.40. The points $\hat{x}_{i}^{\prime}$ are uniform transition points between $x_{1}$ and $x_{2}$, more precisely, the sequences

$$
x_{1}, \hat{x}_{1}^{\prime}, \hat{x}_{2}^{\prime}, x_{2}
$$

are uniformly straight in both $X$ and in $Y$.
Proof. The uniform straightness in $X$ follows from the fact that the above sequence appears in the $\Lambda$-quasigeodesic $\phi$ in $X$ (in the correct order). To prove the uniform straightness in $Y$, note that the concatenation

$$
\psi=\left[x_{1} y_{1}\right]_{Y} \star\left[y_{1} y_{2}\right]_{Y} \star\left[y_{2} x_{2}\right]_{Y}
$$

is a uniform quasigeodesic in $Y$, since each $y_{i}$ is uniformly close to the projection of $x_{i}$ to the $\lambda_{Y}$-quasiconvex subset $F_{w}^{Y} \subset Y$ (again, see Section 2.6.2). Thus, it suffices to show that $\hat{x}_{1}^{\prime}, \hat{x}_{2}^{\prime}$ are uniform $Y$-transition points between $y_{1}, y_{2}$. As in the previous section, consider the nearest-point projections $\bar{y}_{i} \in \zeta_{i}$ of $y_{i}$. According to Lemma 8.30, there exist points

$$
\tilde{y}_{i} \in\left[\bar{x}_{i}, \hat{x}_{i}^{\prime}\right]_{X}, i=1,2,
$$

within distance $C_{8.35}(K)$ from $\bar{y}_{i}$. The points $\bar{y}_{i}$ (and, hence, $\tilde{y}_{i}$ ) are uniformly close to the projections of $y_{i}$ to the quasigeodesic $\phi$ (Lemma 8.30). Hence, the concatenation

$$
\left[y_{1} \tilde{y}_{1}\right]_{X} \star\left[\tilde{y}_{1} \tilde{y}_{2}\right]_{X} \star\left[\tilde{y}_{2} y_{2}\right]_{X}
$$

is a uniform quasigeodesic in $X$, where $\left[\tilde{y}_{1} \tilde{y}_{2}\right]_{X} \subset\left[\bar{x}_{1} \bar{x}_{2}\right]_{X}$. The middle geodesic in this concatenation passes through the points $\hat{x}_{1}^{\prime}, \hat{x}_{2}^{\prime}$ (in this order), implying the uniform straightness of the sequence

$$
y_{1}, \hat{x}_{1}^{\prime}, \hat{x}_{2}^{\prime}, y_{2}
$$

in $Y$, as claimed.
Now, we can finish the Part II. 5 of the proof of Theorem 8.19. The sequence $x_{1}, \hat{x}_{1}^{\prime}, \hat{x}_{2}^{\prime}, x_{2}$ is uniformly straight in both $X$ and in $Y$. The pair $\left(\hat{x}_{1}^{\prime}, \hat{x}_{2}^{\prime}\right) \in F_{w}^{Y} \times F_{w}^{Y}$ is uniformly consistent according to Proposition 8.20 , while both pairs $\left(x_{1}, \hat{x}_{1}^{\prime}\right),\left(\hat{x}_{2}^{\prime}, x_{2}\right)$ are uniformly consistent by Lemma 8.37(2). Therefore, by Lemma 8.18, the pair ( $x_{1}, x_{2}$ ) is $\theta$-consistent for some function $\theta=\theta_{8.38, K}$.

This concludes Part II of the proof.

### 8.5. Part III: Consistency in the general case

Suppose that $x, y \in y$ belong to vertex-spaces $X_{u}, X_{v}$, respectively, $u, v \in V(S)$. Fix $K=K_{0}$. Using Lemma 3.44 and Theorem 6.17, we obtain a horizontal subdivision of the interval $J=\llbracket u, v \rrbracket$, into subintervals $J_{i}=\llbracket u_{i}, u_{i+1} \rrbracket, i=1, \ldots, n$, such that the pairs of distinct flow-spaces $F_{i}^{X}:=F l_{K}^{X}\left(X_{u_{i}}\right)$ have disjoint projections to $T$ and, hence, are $C=$ $C_{6.17}$-cobounded, unless, possibly $i=n ; u=u_{1}, v=u_{n+1}$. (The same, of course also holds for the $Y$-flows.) As in Lemma 3.44, we also define vertices $u_{i}^{\prime \prime}, u_{i+1}^{\prime} \in J_{i}$ such that

1. $u_{i}^{\prime}, u_{i}$ span an edge $e_{i}$ in $T$ (except, possibly, for $i=n+1$, in which case we can have $\left.d_{T}\left(u_{n+1}^{\prime}, u_{n+1}\right) \leq 1\right)$.
2. Each subinterval $\llbracket u_{i}^{\prime}, u_{i} \rrbracket, \llbracket u_{i}, u_{i}^{\prime \prime} \rrbracket, \llbracket u_{i}^{\prime \prime}, u_{i+1}^{\prime} \rrbracket$ is $K$-special. In particular, the subinterval $J_{i}^{\prime}=\llbracket u_{i}, u_{i+1}^{\prime} \rrbracket$ is semispecial.

For each $i$ we define pairs of points $\left(x_{i}^{\prime \prime}, x_{i+1}^{\prime}\right) \in \mathcal{F}_{i}^{X} \times \mathcal{F}_{i+1}^{X}$ realizing the minimal distance between the subsets $\mathcal{F}_{i}^{X}, \mathcal{F}_{i+1}^{X}$ of $X$ unless $i=n$ and $u_{n+1}^{\prime}=u_{n+1}$, in which case we take $x_{n}^{\prime \prime}$ to be the projection of $y$ to $\mathcal{F}_{n}^{X}$.

Figure 37. Projections to $J$.

For each $i$ define the vertices $t_{i}^{\prime}:=\pi\left(x_{i}^{\prime}\right), t_{i}^{\prime \prime}:=\pi\left(x_{i}^{\prime \prime}\right)$ and let $s_{i}^{\prime}, s_{i}^{\prime \prime}$ denote their respective projections to the subtree $S \subset T$.

Lemma 8.41. Let $b_{i}^{\prime}$ (resp. $\left.b_{i}^{\prime \prime}, v_{i}^{\prime}, v_{i}^{\prime \prime}\right)$ denote the projection to $J$ of the vertices $t_{i}^{\prime}$ (resp. $\left.t_{i}^{\prime \prime}, \pi\left(y_{i}^{\prime}\right), \pi\left(y_{i}^{\prime \prime}\right)\right)$. Then:

1. The projections $b_{i}^{\prime}, v_{i}^{\prime}$ lie in the subinterval $\rrbracket u_{i-1}^{\prime \prime}, u_{i}^{\prime} \rrbracket$.
2. The projections $b_{i}^{\prime \prime}, v_{i}^{\prime \prime}$ lie in the subinterval $\llbracket u_{i}, u_{i}^{\prime \prime} \rrbracket$.

Proof. We will prove the claim for the vertex $v_{i}^{\prime}$, since the rest is proven by the same argument.

First of all,

$$
\pi\left(F_{i}^{Y}\right) \subset \pi\left(F_{i}^{X}\right)
$$

and, by the definition of the horizontal subdivision of the interval $J, \pi\left(F_{i}^{X}\right)$ intersects $J$ in a subinterval of $\rrbracket u_{i-1}^{\prime \prime}, u_{i}^{\prime \prime} \rrbracket$. Thus, $v_{i}^{\prime}$ belongs to $\rrbracket u_{i-1}^{\prime \prime}, u_{i}^{\prime \prime} \rrbracket$. Suppose, for the sake of a contradiction, that $v_{i}^{\prime}$ is in the interval $\llbracket u_{i}, u_{i}^{\prime \prime} \rrbracket$. Then each geodesic connecting $y_{i-1}^{\prime \prime}$ to $y_{i}^{\prime}$ goes through the edge-space $X_{e}$ of the edge

$$
e=\left[u_{i}^{\prime}, u_{i}\right]
$$

before reaching $x_{i}^{\prime}$. But then, this geodesic also passes through the subset

$$
X_{e u_{i}^{\prime}} \subset X_{u_{i}^{\prime}} .
$$

Since $K \geq 1$, the entire subset $X_{e u_{i}^{\prime}}$ is contained in the flow-space $F l_{K}^{Y}\left(X_{u_{i}}\right)$. Hence, $y_{i}^{\prime}$ cannot possibly be the $Y$-projection of $y_{i}^{\prime \prime}$ to $F_{i}^{Y}$. A contradiction.

Corollary 8.42. The pairs $\left(y_{i}^{\prime \prime}, y_{i+1}^{\prime}\right)$ are uniformly consistent.
Proof. Let $v_{i}^{\prime \prime}, v_{i+1}^{\prime}$ denote the projections of $\pi\left(y_{i}^{\prime \prime}\right), \pi\left(y_{i+1}^{\prime}\right)$ to $J$. By the lemma, both $v_{i}^{\prime \prime}, v_{i+1}^{\prime}$ lie in the interval $J_{i}^{\prime}=\llbracket u_{i}, u_{i+1}^{\prime} \rrbracket$, which is semispecial. Moreover, $y_{i}^{\prime \prime} \in F l_{K}^{Y}\left(X_{u_{i}}\right)$ and $y_{i}^{\prime} \in F l_{K}^{Y}\left(X_{u_{i+1}^{\prime}}\right)$. Thus,

$$
\left(y_{i}^{\prime \prime}, y_{i+1}^{\prime}\right) \in F l_{K}^{Y}\left(X_{J_{i}^{\prime}}\right)
$$

and, hence, the statement is a special case of Proposition 8.38.
Our next task is to relate the points $x_{i}^{\prime}, y_{i}^{\prime}$ and also relate the points $x_{i}^{\prime \prime}, y_{i}^{\prime \prime}$. Since $y_{i}^{\prime}$ is in $Y$, the segment $\left[y_{i}^{\prime} x_{i}^{\prime}\right]_{X}$ has to cross the vertex-space $X_{s_{i}^{\prime}}$; the same holds for the segment $\left[y_{i}^{\prime \prime} x_{i}^{\prime \prime}\right]_{X}$ and $X_{s_{i}^{\prime \prime}}$. We define the points $\tilde{y}_{i}^{\prime} \in\left[y_{i}^{\prime} x_{i}^{\prime}\right]_{X}, \tilde{y}_{i}^{\prime \prime} \in\left[y_{i}^{\prime \prime} x_{i}^{\prime \prime}\right]_{X}$ by the condition that the subsegments

$$
\left[\tilde{y}_{i}^{\prime} x_{i}^{\prime}\right]_{X} \subset\left[y_{i}^{\prime} x_{i}^{\prime}\right]_{X}
$$

and

$$
\left[\tilde{y}_{i}^{\prime \prime} x_{i}^{\prime \prime}\right]_{X} \subset\left[y_{i}^{\prime \prime} x_{i}^{\prime \prime}\right]_{X}
$$

are the smallest subsegments terminating in $x_{i}^{\prime}$, $x_{i}^{\prime \prime}$, with the property that $\tilde{y}_{i}^{\prime} \in X_{s_{i}^{\prime}}, \tilde{y}_{i}^{\prime \prime} \in X_{s_{i}^{\prime \prime}}$. (See Figure 38.) Thus,

$$
Y \cap\left[\tilde{y}_{i}^{\prime} x_{i}^{\prime}\right]_{X} \backslash\left\{\tilde{y}_{i}^{\prime}\right\}=\emptyset,
$$

and, similarly, for $\left[\tilde{y}_{i}^{\prime \prime} x_{i}^{\prime \prime}\right]_{X}$.
Similarly, define points $\hat{y}_{i}^{\prime \prime}, \hat{y}_{i+1}^{\prime} \in\left[x_{i}^{\prime \prime} x_{i+1}^{\prime}\right]_{X}$ such that

$$
\left[\hat{y}_{i}^{\prime} x_{i}^{\prime}\right]_{X} \subset\left[x_{i-1}^{\prime \prime} x_{i}^{\prime}\right]_{X},\left[\hat{y}_{i}^{\prime \prime} x_{i}^{\prime \prime}\right]_{X} \subset\left[x_{i+1}^{\prime} x_{i}^{\prime \prime}\right]_{X}
$$

are the smallest subsegments terminating in $x_{i}^{\prime}, x_{i}^{\prime \prime}$ with $\hat{y}_{i}^{\prime} \in X_{s_{i}^{\prime}}, \hat{y}_{i}^{\prime \prime} \in X_{s_{i}^{\prime \prime}}$. Observe that the concatenations

$$
\beta_{i}:=\left[y_{i}^{\prime \prime} x_{i}^{\prime \prime}\right]_{X} \star\left[x_{i}^{\prime \prime} x_{i+1}^{\prime}\right]_{X} \star\left[x_{i+1}^{\prime} y_{i+1}^{\prime}\right]_{X}
$$

Figure 38. Transition points
are uniform quasigeodesics in $X$ since $x_{i}^{\prime \prime} \in F_{i}^{X}, x_{i+1}^{\prime} \in F_{i+1}^{X}$ realize the minimal distance between these two uniformly quasiconvex subsets of $X$ and $y_{i}^{\prime \prime} \in F_{i}^{Y} \subset F_{i}^{X}, y_{i+1}^{\prime} \in F_{i+1}^{Y} \subset$ $F_{i+1}^{X}$. Both

$$
\zeta_{i}^{\prime}=\left[\hat{y}_{i}^{\prime} x_{i}^{\prime}\right]_{X} \cup\left[x_{i}^{\prime} \tilde{y}_{i}^{\prime}\right]_{X}, \zeta_{i}^{\prime \prime}=\left[\hat{y}_{i}^{\prime \prime} x_{i}^{\prime \prime}\right]_{X} \cup\left[x_{i}^{\prime \prime} \tilde{y}_{i}^{\prime \prime}\right]_{X}
$$

are detour subpaths in $\beta_{i}$, containing the points $x_{i}^{\prime}, x_{i}^{\prime \prime}$ respectively.
Lemma 8.43. 1. The pairs $\left(\hat{y}_{i}^{\prime \prime}, \hat{y}_{i+1}^{\prime}\right) \in Y^{2}$ are uniformly consistent.
2. The distances $d\left(y_{i}^{\prime}, \tilde{y}_{i}^{\prime}\right), d\left(y_{i}^{\prime \prime}, \tilde{y}_{i}^{\prime \prime}\right)$ are uniformly bounded.

Proof. Part 1. By the previous corollary, the pair $\left(y_{i}^{\prime \prime}, y_{i+1}^{\prime}\right)$ is uniformly consistent. In particular, the path

$$
\hat{\beta}_{i}=\left[y_{i}^{\prime \prime} \tilde{y}_{i}^{\prime \prime}\right]_{X} \star\left[\tilde{y}_{i}^{\prime \prime} \hat{y}_{i}^{\prime \prime}\right]_{X_{i}^{\prime \prime}} \star\left[\hat{y}_{i}^{\prime} \hat{y}_{i+1}^{\prime}\right]_{X} \star\left[\hat{y}_{i+1}^{\prime} \tilde{y}_{i+1}^{\prime}\right]_{X_{i+1}^{\prime}} \star\left[\tilde{y}_{i+1}^{\prime} \widehat{y_{i+1}^{\prime}}\right]_{X}
$$

is uniformly quasigeodesic. Thus, the geodesic $\left[y_{i}^{\prime \prime} y_{i+1}^{\prime}\right]_{Y}$ passes within uniform distance $D$ from the points $\tilde{y}_{i}^{\prime \prime}, \hat{y}_{i}^{\prime \prime}, \hat{y}_{i+1}^{\prime}, \tilde{y}_{i+1}^{\prime}$ (in this order). Taking into account uniform consistency of the pairs $\left(y_{i}^{\prime \prime}, y_{i+1}^{\prime}\right.$ ) and Remark 8.14, we conclude uniform consistency of the pairs $\left(\hat{y}_{i}^{\prime \prime}, \hat{y}_{i+1}^{\prime}\right)$.

Part 2. We will estimate the second distance, $d\left(y_{i}^{\prime \prime}, \tilde{y}_{i}^{\prime \prime}\right)$, since the proof for the first one is similar. Since $F_{i}^{X}$ is $\lambda_{X}$-quasiconvex in $X$, and $\left(x_{i}^{\prime}, y_{i}^{\prime}\right) \in F_{i}^{X} \times F_{i}^{X}$, the point $\tilde{y}_{i}^{\prime}$ lies within distance $\lambda_{X}$ from a point $q$ in $F_{i}^{X}$. The point $q$ might not be in $F_{i}^{Y}=F_{i}^{X} \cap Y$, but it is within distance $K \lambda_{X}$ from $F_{i}^{X} \cap X_{s_{i}^{\prime}} \subset F_{\lambda}^{Y}$. In Part 1 we observed that the geodesic $\left[y_{i}^{\prime \prime} y_{i+1}^{\prime}\right]_{Y}$ passes (at some point $p$ ) within uniform distance $D$ from the point $\tilde{y}_{i}^{\prime \prime}$. Thus, we found a point $p \in\left[y_{i}^{\prime \prime} y_{i+1}^{\prime}\right]_{Y}$ within distance $D+(K+1) \lambda$ from $F_{i}^{Y}$. It follows that

$$
d_{Y}\left(p, y_{i}^{\prime \prime}\right) \leq D+(K+1) \lambda_{X}
$$

and, hence,

$$
d_{Y}\left(\tilde{y}_{i}^{\prime \prime}, y_{i}^{\prime \prime}\right) \leq 2 D+(K+1) \lambda_{X} .
$$

Remark 8.44. While it is not needed for our purposes, one can prove similarly to Lemma 8.33, that the points $y_{i}^{\prime}, y_{i}^{\prime \prime}$ are uniformly close to the projections (taken in the vertex-spaces $X_{s_{i}^{\prime}}, X_{s_{i}^{\prime \prime}}$ respectively) of the points $\hat{y}_{i}^{\prime}, \hat{y}_{i}^{\prime \prime}$ to the $4 \delta_{0}$-quasiconvex subsets

$$
F_{i}^{Y} \cap X_{s_{i}^{\prime}}, F_{i}^{Y} \cap X_{s_{i}^{\prime \prime}}
$$

respectively. This provides a description (up to a uniform error) of the points $y_{i}^{\prime}, y_{i}^{\prime \prime}$ in terms of $x_{i-1}^{\prime \prime}, x_{i}^{\prime}, x_{i}^{\prime \prime}$.

Lemma 8.45. The pairs ( $\hat{y}_{i}^{\prime}, \hat{y}_{i}^{\prime \prime}$ ) are uniformly consistent.
Proof. Each interval

$$
I_{i}=\llbracket s_{i}^{\prime}, s_{i}^{\prime \prime} \rrbracket \subset T
$$

is contained $\llbracket t_{i}^{\prime}, t_{i}^{\prime \prime} \rrbracket$ and intersects $J$ along the interval $\llbracket b_{i}^{\prime}, b_{i}^{\prime \prime} \rrbracket$, which, in turn, contains the vertex $u_{i}$, see Lemma 8.41. Since $F_{i}^{Y}$ has nonempty intersection with both $X_{s_{i}^{\prime}}, X_{s_{i}^{\prime \prime}}$, it follows that the interval $I_{i}$ is semispecial (it is the union of special subintervals $\llbracket s_{i}^{\prime}, u_{i} \rrbracket$, $\left.\llbracket s_{i}^{\prime \prime}, u_{i} \rrbracket\right)$. Thus,

$$
y_{i}^{\prime}, y_{i}^{\prime \prime} \in X_{I_{i}} \subset F l_{K}^{Y}\left(X_{I_{i}}\right)
$$

and, hence, the pair $\left(\hat{y}_{i}^{\prime}, \hat{y}_{i}^{\prime \prime}\right)$ is uniformly consistent by Proposition 8.38.
We now can finish the proof of Theorem 8.19. For each $i$, the points $\hat{y}_{i}^{\prime \prime}, \hat{y}_{i+1}^{\prime}$ are both $X$ and $Y$-transition points between, respectively, $x_{i}^{\prime \prime}, x_{i+1}^{\prime}$ and $y_{i}^{\prime \prime}, y_{i+1}^{\prime}$. The sequence

$$
x, \hat{y}_{1}^{\prime \prime}, \hat{y}_{2}^{\prime}, \hat{y}_{2}^{\prime \prime}, \ldots, \hat{y}_{n}^{\prime}, \hat{y}_{n}^{\prime \prime}, \hat{y}_{n+1}^{\prime}, y
$$

is uniformly straight in both $X$ and in $Y$ and the consecutive pairs of points in this sequence are uniformly consistent. Now, the uniform consistency of the pairs $(x, y)$ follows from Lemma 8.18.

### 8.6. The existence of CT-maps for subtrees of spaces

We finally are ready to prove the main result of this chapter:
Theorem 8.46. Let $\mathfrak{X}=(\pi: X \rightarrow T)$ be a tree of hyperbolic spaces with hyperbolic total space $X$ and let $\mathfrak{Y}=(\pi: Y \rightarrow S)$ be a subtree of spaces in $\mathfrak{X}$, where $S \subset T$ is a subtree and $Y=\pi^{-1}(S)$. Then the inclusion map $Y \rightarrow X$ admits a CT-extension.

Proof. We will derive this result from Theorem 8.19. Fix $p \in Y$ and suppose that $\left(y_{n}\right),\left(y_{n}^{\prime}\right)$ are sequences in $Y$ such that

$$
\lim _{n \rightarrow \infty}\left(y_{n} \cdot y_{n}^{\prime}\right)_{p}^{Y}=\infty
$$

where the superscript $Y$ refers to the Gromov-product of the intrinsic path-metric of $Y$. Equivalently, for the geodesic $\beta_{n}=\left[y_{n} y_{n}^{\prime}\right]_{Y} \subset Y$ we have

$$
\lim _{n \rightarrow \infty} d\left(p, \beta_{n}\right)=\infty
$$

For the sake of contradiction, assume that the corresponding $X$-geodesics $\alpha_{n}=\left[y_{n} y_{n}^{\prime}\right]_{X} \subset X$ all pass through a ball $B_{X}(y, R) \subset X$ for some fixed $R$ (which is equivalent to saying that the sequence $\left(y_{n}, y_{n}^{\prime}\right)_{p}^{X}$ does not diverge to infinity), i.e. there exist points

$$
q_{n} \in \alpha_{n} \cap B_{X}(p, R)
$$

By Theorem 8.19, each $\hat{\alpha}_{n}$ is a $\Lambda$-quasigeodesic in $Y$ connecting $y_{n}, y_{n}^{\prime}$, for some $\Lambda$ independent of $n$. By the Morse Lemma (Lemma 1.53),

$$
\operatorname{Hd}_{Y}\left(\beta_{n}, \hat{\alpha}_{n}\right) \leq D=D\left(\delta_{Y}, \Lambda\right)
$$

There are two cases which may occur:
a. $q_{n} \in Y$. Then (by the definition of $\hat{\alpha}_{n}$ ) $q_{n} \in \hat{\alpha}_{n}$, hence,

$$
d_{X}\left(p, \beta_{n}\right) \leq D+R
$$

for all $n$, which is a contradiction.
b. $q_{n} \notin Y$. Let $\zeta_{n}=\left[z_{n} z_{n}^{\prime}\right]_{X} \subset \alpha_{n}$ be a detour subpath in $\alpha_{n}$ containing $q_{n}$; the endpoints $z_{n}, z_{n}^{\prime}$ of $\zeta_{n}$ belong to a vertex-space $X_{v_{n}} \subset Y$. Since $p \in Y, q_{n} \notin Y$, the vertex-space $X_{v_{n}}$ separates $p$ from $q_{n}$ and, hence, the geodesic [ $\left.p q_{n}\right]_{X}$ has to pass through $X_{v_{n}}$ at some point $p_{n} \in X_{v_{n}}$. We, obviously, have

$$
d_{X}\left(p, p_{n}\right) \leq R
$$

Thus, by Corollary 8.27, points $p_{n}$ are all uniformly close (within distance $r$ depending only on the parameters of $\mathfrak{X}$ ) to the geodesic $\left[z_{n} z_{n}^{\prime}\right]_{X_{v n}} \subset \hat{\alpha}_{n}$. Therefore,

$$
d_{X}\left(p, \beta_{n}\right) \leq D+R+r
$$

which is again a contradiction.

### 8.7. Fibers of CT-maps

Let $\mathfrak{X}=(\pi: X \rightarrow T)$ be a tree of hyperbolic spaces with hyperbolic total space $X$. According to Theorem 8.46, for every subtree $S \subset T$ and $Y=X_{S}$, the inclusion map

$$
f_{Y, X}: Y=X_{S} \rightarrow X
$$

admits a Cannon-Thurston extension

$$
\partial_{Y, X}:=\partial_{\infty} f_{Y, X}: \partial_{\infty} Y \rightarrow \partial_{\infty} X
$$

For the rest of the chapter, we will be working under the extra assumptions that $X$ is a proper metric space, i.e. that an abstract tree of spaces $\mathfrak{X}$ admits a proper total space. Note that if some edge-spaces are non-discrete, the total space $X$ defined in the proof of Theorem 2.14 need not be proper even if $V(T)=\{v, w\}$ and $X_{v}, X_{w}, X_{[v, w]}$ are proper. However, this $X$ will be proper (a locally finite metric graph) under the following conditions:

1. Each vertex-space $X_{v}$ is a locally-finite graph (with the standard graph-metric).
2. All edge-spaces $X_{e}$ are discrete and $X_{e v}=f_{e v}\left(X_{e}\right) \subset V\left(X_{v}\right)$ for each edge $e$ and incident vertex $v$.
3. Each finite subset of each vertex-space $X_{v}$ meets only finitely many subsets of the form $X_{e v}$, where $e$ 's are edges incident to $v$.

Proposition 8.47. Suppose that $\mathfrak{X}$ has a proper total space $X$. Then there exists a number $r$, depending only on $\mathfrak{X}$ and $X$, for which the following holds. For each $Y=X_{S} \subset X$, if $\xi_{ \pm} \in \partial_{\infty} Y$ are two distinct points such that $\partial_{Y, X}\left(\xi_{+}\right)=\partial_{Y, X}\left(\xi_{-}\right)$, then there exists a vertex $v \in S$ and two ideal boundary points $\xi_{ \pm}^{\prime} \in \partial_{\infty} X_{v}$ such that:

1. $\partial_{X_{\nu}, Y}\left(\xi_{ \pm}^{\prime}\right)=\xi_{ \pm}$.
2. The $Y$-geodesic $\eta: \mathbb{R} \rightarrow Y$, connecting $\xi_{+}, \xi_{-}$, is contained in the $r$-neighborhood of a vertex space $X_{v}, v \in S$, and, moreover, is $r$-Hausdorff-close to a vertical geodesic $\alpha$ in $X_{v}$.

Proof. Set $x_{n}:=\eta(n), n \in \mathbb{Z}$. Define subarcs of the geodesic $\eta$ by

$$
\eta_{n}:=\left[x_{-n} x_{n}\right]_{Y}, n \in \mathbb{N},
$$

and geodesics $\beta_{n}=\left[x_{-n} x_{n}\right]_{X}$.
Since $\partial_{Y, X}\left(\xi_{+}\right)=\partial_{Y, X}\left(\xi_{-}\right)$, we have that

$$
\lim _{n \rightarrow \infty} d_{X}\left(x_{0}, \beta_{n}\right)=\infty
$$

Thus, $x_{0}$ cannot be uniformly close to $\beta_{n} \cap Y$. At the same time, since $x_{0}$ belongs to each $\eta_{n}$ (which, by Theorem 8.19 , is uniformly close to the $\Lambda$-quasigeodesic $\hat{\beta}_{n}$ in $Y$ ), the point $x_{0}$ lies in the $C$-neighborhood of one of the replacement $\operatorname{arcs} \hat{\zeta}_{n}=\left[p_{n} q_{n}\right]_{V_{v_{n}}} \subset \hat{\eta}_{n}$, where $\Lambda$ and $C$ depend only on the parameters of $\mathfrak{X}$. In particular, $d_{X}\left(x_{0}, X_{v_{n}}\right) \leq C$ for all $n$. Since $X$ is assumed to be proper, there are only finitely many vertex-spaces in $X$ which can intersect $B\left(x_{0}, C\right)$. It follows that there is an infinite subset $M \subset \mathbb{N}$ and a vertex $v \in S$ such that for all $m \in M, v_{m}=v$. At the same time, since the distances $d\left(x_{0}, \beta_{n}\right)$ diverge to infinity, we also have

$$
\lim _{n \rightarrow \infty} d\left(x_{0}, p_{n}\right)=\infty, \quad \lim _{n \rightarrow \infty} d\left(x_{0}, q_{n}\right)=\infty
$$

Hence, after passing to a further subsequence, the sequences $\left(p_{m}\right)_{m \in M},\left(q_{m}\right)_{m \in M}$, diverge in $X_{v}$ to two ideal boundary points $\xi_{ \pm}^{\prime}$.

By continuity at infinity of the CT-map $\partial_{X_{v}, Y}: \partial_{\infty} X_{v} \rightarrow \partial_{\infty} Y$, it follows that

$$
\partial_{X_{v}, Y}\left(\xi_{ \pm}^{\prime}\right)=\xi_{ \pm} .
$$

After passing to a subsequence once more, we can assume that the sequence of geodesics $\hat{\zeta}_{n} \subset X_{v}$ converges to a complete geodesic $\zeta \subset X_{v}$ asymptotic to the points $\xi_{ \pm}^{\prime}$. Since geodesics $\hat{\zeta}_{n}$ are $\Lambda$-quasigeodesics in $Y$, so is their limit $\alpha$. Since the $Y$-geodesic $\eta$ is also asymptotic to $\xi_{ \pm}$, it follows that $\eta, \alpha$ are within Hausdorff distance $r:=2 D_{1.53}\left(\delta_{Y}, \Lambda\right)$, which depends only on the parameters of $\mathfrak{X}$. It also follows that $\eta$ is contained in $N_{r}\left(X_{\nu}\right)$.

In the following addendum to this proposition we describe more precisely (up to a uniform error) the nature of geodesic segments $\beta_{-m, n}$ connecting the points $x_{-m}, x_{n}, n, m \in$ $\mathbb{N}$, in the setting of the theorem. Since the points $x_{-m}, x_{n}$ belong to the $r$-neighborhood of $X_{v}$, we will be considering instead of $\beta_{-m, n}$ 's the uniform quasigeodesics $c_{-m, n}$ (from the slim combing of $X$ described in Section 7.1) connecting points $y_{-m}, y_{n}, m, n \in \mathbb{N}$, where $y_{i}:=\alpha(i), i \in \mathbb{Z}$. We will see that the path $c_{-m, n}$ first diverges away from $X_{v}$ (in the metric of $X$ ) at a linear speed and then converges back to $X_{v}$ at a linear speed. We refer the reader to Section 7.1 (step I.1) for the description of uniform quasigeodesics connecting points in narrow carpets used in the proof of the next proposition.

Remark 8.48. In what follows, we will frequently use the following notation. Let $\mathfrak{U}=\mathfrak{M}(\alpha)$ be a $(K, C)$-narrow carpet with the narrow end $\beta \subset X_{w}$, bottom and top sections $\gamma_{-}, \gamma_{+}$. Then we define the path $c=c_{\mathfrak{2}}$ as the concatenation

$$
\gamma_{-} \star \beta \star \gamma_{+}
$$

connecting the bottom and and the top points of the segment $\alpha \subset X_{u}$. Such paths will be uniform (with qi constants depending on $K$ and $C$ ) quasigeodesics in $\mathfrak{H}$ and, hence, in $X$, as long as for each vertex $v \in X_{v}$, the length of $A_{v}$ is $\geq M_{\bar{K}}$, see Section 4.1 or Section 7.1, Step I.1.

Proposition 8.49. 1. For all $n>0, m>0$, the segment $\alpha_{-m, n}=\left[y_{-m} y_{n}\right]_{X_{v}}$ bounds a certain $(K, C)$-narrow carpet $\mathfrak{H}_{-m, n}=\mathfrak{H}_{K}\left(\alpha_{-m, n}\right)$ in X over the interval $J_{-m, n}=\llbracket v, w_{-m, n} \rrbracket$. Here $K$ and $C$ depend only on the parameters of $\mathfrak{X}$.
2. For $n>0, m>0$, the uniform quasigeodesic $c_{-m, n}$ in $A_{m, n} \subset X$ connecting points $y_{-m}, y_{n}$ is the concatenation

$$
\gamma_{-m} \star \beta_{-m, n} \star \gamma_{n},
$$

where $\beta_{-m, n}$ is a vertical geodesic in $X_{w_{-m, n}}$ of length $\leq C$ and $\gamma_{-m}, \gamma_{n}$ are $K$-qi sections over the interval $J_{-m, n}=\llbracket v, w_{-m, n} \rrbracket$.

Proof. Set $K:=K_{0}$ (defined in Notation 2.6.4). Consider maximal $K$-qi sections $\Sigma_{-m}, \Sigma_{n}$ in $X$ through the points $y_{-m}, y_{n}$. If, for some $n_{0}, m_{0}$, these sections have vertical separation $\geq M_{K}$ everywhere, then they are uniformly cobounded in $X$, see 7.1. In this situation, for all $n \geq n_{0}, m \geq m_{0}$, the path $c_{-m, n}$ (and, hence, the geodesic $\beta_{-m, n}=\left[x_{-m} x_{n}\right]_{X}$ ) has to come uniformly close to a pair of points $x^{-} \in \Sigma_{-m_{0}}, x^{+} \in \Sigma_{n_{0}}$, contradicting the assumption that

$$
\lim _{n \rightarrow \infty, m \rightarrow \infty} d\left(y_{0}, \beta_{-m, n}\right)=\infty
$$

Thus, for each pair $(m, n)$ there is a vertex $w_{m, n}$ and a pair of $K$-qi leaves $\gamma_{n} \subset \Sigma_{n}, \gamma_{-m} \subset$ $\Sigma_{-m}$ over an interval $J_{m, n}=\llbracket v, w_{m, n} \rrbracket$, with vertical separation $\geq M_{K}$, such that

$$
d_{X_{w_{m, n}}}\left(\gamma_{-m}\left(w_{m, n}\right), \gamma_{n}\left(w_{m, n}\right)\right) \leq M_{K} .
$$

The uniform quasigeodesic $c_{-m, n}$ connecting points $y_{-m}, y_{n}$ then is defined as the concatenation

$$
\gamma_{-m} \star \beta_{-m, n} \star \gamma_{n}, \quad \beta_{-m, n}=\left[\gamma_{-m}\left(w_{-m, n}\right) \gamma_{n}\left(w_{-m, n}\right)\right]_{X_{w-m, n}} .
$$

(This argument is similar to the proof of Proposition 7.2.)
We can now give a complete description of pairs of distinct points in the fibers of the CT-map $\partial_{Y, X}$. Recall that the metric space $X$ is assumed to be proper.

Theorem 8.50. There are constants $K, C$ depend only on the parameters of $\mathfrak{X}$ and $a$ function $D=D(k)$ such that the following hold:

1. Suppose that $\xi^{ \pm}$are distinct points in $\partial_{\infty} Y$ such that $\partial_{Y, X}\left(\xi^{-}\right)=\partial_{Y, X}\left(\xi^{+}\right)$. Then there exists a vertex-space $X_{u} \subset Y$ and a complete geodesic $\alpha: \mathbb{R} \rightarrow X_{u}$, which is a uniform quasigeodesic in $Y$ asymptotic to $\xi^{ \pm}$, such that the intervals $\alpha_{-m, n}=[\alpha(-m) \alpha(n)]_{X_{u}} \subset \alpha$, bound $(K, C)$-narrow carpets $\mathfrak{A}\left(\alpha_{-m, n}\right)$ in $X$ for all $m>0, n>0$.
2. Conversely, if $X_{u}$ is a vertex-space of $\mathfrak{Y}$, $\alpha \subset X_{u}$ is a complete geodesic asymptotic to distinct points $\xi^{ \pm} \in \partial_{\infty} Y$, such that each subinterval $\alpha_{-m, n}$ as above bounds a $(K, C)-$ narrow carpet $\mathfrak{H}\left(\alpha_{-m, n}\right)$ in $X$, then $\partial_{Y, X}\left(\xi^{-}\right)=\partial_{Y, X}\left(\xi^{+}\right)$.
3. Suppose that $X_{u}$ is a vertex-space of $\mathfrak{Y}$, $\alpha \subset X_{u}$ is a complete geodesic asymptotic to distinct points $\xi^{ \pm} \in \partial_{\infty} Y$. Then $\partial_{Y, X}\left(\xi^{-}\right) \neq \partial_{Y, X}\left(\xi^{+}\right)$if and only if for some (equivalently, every) $k \geq 1$, there exist points $x, y \in \alpha$ and maximal $k$-qi sections $\Sigma_{x}, \Sigma_{y}$ over, possibly different, subtrees $T_{x}, T_{y}$ in $T$ through the points $x, y$ such that the vertical separation between $\Sigma_{x}, \Sigma_{y}$ over every vertex of $T_{x} \cap T_{y}$ is $\geq D$.

Proof. We take $K=K_{0}$ and $C=M_{\bar{K}}$.

1. The first part of the theorem is the content of Propositions 8.47 and 8.49.
2. Since the lengths of the intervals $\alpha_{-m, n}=\left[y_{-m} y_{n}\right]_{X_{u}}$ diverge to $\infty$ as $m \rightarrow \infty, n \rightarrow \infty$, for all sufficiently large $m, n$, without loss of generality, we may assume that the vertical separation between the top and the bottom of each carpet $\mathfrak{A}\left(\alpha_{-m, n}\right)$ is $\geq M_{K}$. (Otherwise, since $C=M_{\bar{K}} \geq M_{K}$, we take a smaller $(K, C)$-subcarpet $\mathfrak{H}^{\prime}\left(\alpha_{-m, n}\right) \subset \mathfrak{A}\left(\alpha_{-m, n}\right)$ containing no vertical intervals of length $<M_{K}$.) Now, just as in proof of Proposition 7.2, each carpet $\mathfrak{A}\left(\alpha_{-m, n}\right)$ defines a uniform $X$-quasigeodesic $c_{-m, n}$ connecting $y_{-m}$ to $y_{n}$ and

$$
d_{X}\left(y_{0}, c_{-m, n}\right) \geq \text { length }\left(\pi\left(A\left(\alpha_{-m, n}\right)\right)\right)
$$

Thus,

$$
\lim _{m \rightarrow \infty, n \rightarrow \infty} d_{X}\left(x_{0},\left[y_{-m} y_{n}\right]_{X}\right)=\infty
$$

and, therefore, $\partial_{Y, X}\left(\xi^{-}\right)=\partial_{Y, X}\left(\xi^{+}\right)$.
3. This part of the proof is similar to that of Proposition 8.47. We choose $D=M_{k}$.
(a) Suppose that sections $\Sigma_{x}, \Sigma_{y}$ exist. After reparameterizing $\alpha$, we can assume that $x=\alpha\left(-m_{0}\right), y=\alpha\left(n_{0}\right), m_{0}>0, n_{0}>0$. There is a ladder $\mathfrak{L}_{X, k}(\alpha) \subset \mathfrak{X}$ containing sections

Figure 39
$\Sigma_{x}, \Sigma_{y}$. Consider the combing paths $c_{-m, n}=c(\alpha(-m), \alpha(n))$ in the ladder $\mathfrak{L}_{X, k}(\alpha)$ for $n \geq$ $n_{0}, m \geq m_{0}$. These paths have to go through both sections $\Sigma_{x}, \Sigma_{y}$ and, hence, pass uniformly close to a pair of points $x^{\prime}, y^{\prime}$ (independent of $m, n$ ) in these sections realizing the minimal fiberwise distance between $\Sigma_{x}, \Sigma_{y}$ (the sections are cobounded in $L_{X, k}(\alpha)$, see Section 7.1). Thus, for $y_{0}=\alpha(0)$, the minimal distances $d_{X}\left(y_{0}, c_{-m, n}\right)$ are uniformly bounded (from above), hence,

$$
\lim \sup _{m, n \rightarrow \infty}(\alpha(-m) \cdot \alpha(n))_{y_{0}}<\infty,
$$

and, therefore, $\partial_{Y, X}\left(\xi^{-}\right) \neq \partial_{Y, X}\left(\xi^{+}\right)$.
(b) Suppose that the points $x, y$ do not exist. Take arbitrary maximal $k$-qi sections $\Sigma_{y_{-m}}, \Sigma_{y_{n}}$ in $X$ through the points $y_{-m}=\alpha(-m), y_{n}=\alpha(n)$. Then for all $m \geq 0, n \geq 0$ the minimal vertical separation between $\Sigma_{y_{-m}}, \Sigma_{y_{n}}$ is $\leq M_{k}$ and, hence, each interval $\alpha_{-m, n}=$ $\left[y_{-m} y_{n}\right]_{X_{u}} \subset \alpha$ bounds a $\left(k, M_{k}\right)$-narrow carpet $\mathfrak{A}\left(\alpha_{-m, n}\right)$ in $X$. According to Part 2 , then $\partial_{Y, X}\left(\xi^{-}\right)=\partial_{Y, X}\left(\xi^{+}\right)$.

Remark 8.51. Note that in Part 2 of the theorem we can bound from above lengths of the intervals $\llbracket u, w_{m, n} \rrbracket=\pi\left(\mathfrak{H}\left(\alpha_{-m, n}\right)\right)$ in terms of lengths of the segments $\alpha_{-m, n}$ : In view of the exponential flaring satisfied by $\mathfrak{X}$ (see Lemma 2.55 and Proposition 2.56) there exists a constant $\lambda$ (depending only on $K$ and the parameters of $\mathfrak{X}$ ) such that

$$
\text { length }\left(\alpha_{-m, n}\right) \geq \lambda^{t} C, \quad t=d_{T}\left(u, w_{m, n}\right)
$$

Thus,

$$
d_{T}\left(u, w_{m, n}\right) \leq \tau_{m, n}:=\log _{\lambda}\left(\operatorname{length}\left(\alpha_{-m, n}\right)\right)-\log _{\lambda}(C)
$$

As an application of Part 1 of the theorem we obtain the following:
Corollary 8.52. Suppose that $\gamma$ is a geodesic in $Y$ whose projection to $T$ is unbounded. Then $\gamma$ is not a leaf of the CT-map $\partial_{Y, X}$.

### 8.8. Boundary flows and CT laminations

In this section we will be using the notion of ideal boundary flows $F l_{t}$ (where $t$ 's are vertices and edges of the tree $T$ ) which are defined and discussed in Section 3.3.4.

Before proving the next proposition we will need two definitions which will be discussed in much greater detail in Section 8.9. Recall that $\partial_{\infty}(Z, X)$ denotes the limit set (relative ideal boundary) of a subset $Z \subset X$. Recall also that $\Lambda(Y, X)$ denotes the CannonThurston lamination of a hyperbolic subspace $Y$ in a hyperbolic space $X$, see Definition 8.8.

Definition 8.53. Consider a point $\xi \in \partial_{\infty} T$ and a geodesic ray $v \xi$ in $T$ joining a vertex $v \in T$ to $\xi$. Define $\xi$-relative ideal boundary

$$
\partial_{\infty}^{\xi}\left(X_{v}, X\right):=\left\{\eta \in \partial_{\infty}\left(X_{v}, X\right): \exists \text { a qi section } \gamma \text { over } \nu \xi, \gamma(\infty)=\eta\right\}
$$

and

$$
\Lambda^{\xi}\left(X_{v}, X\right)=\left\{\left\{z^{-}, z^{+}\right\} \in \Lambda\left(X_{v}, X\right): \partial_{X_{v}, X}\left(z^{ \pm}\right) \in \partial_{\infty}^{\xi}\left(X_{v}, X\right)\right\} .
$$

Note that, by the definition of $\Lambda\left(X_{v}, X\right), \partial_{X_{v}, X}\left(z^{+}\right)=\partial_{X_{v}, X}\left(z^{-}\right)$.
While the definition of $\Lambda^{\xi}\left(X_{v}, X\right)$ at this point looks rather unmotivated, in the next section we will prove that it equals the the $\xi$-ending lamination $\Lambda\left(X_{v}, X_{v \xi}\right)$. Examples of points in $\partial_{\infty}^{\xi}\left(X_{v}, X\right)$ are given by points $\gamma(\infty)$ for qi sections $\gamma$ that are limits (as $\left.n \rightarrow \infty\right)$ of bottom sections of carpets $\mathfrak{A}\left(\alpha_{-m_{0}, n}\right)$ appearing in the proof of Theorem 8.50.

Proposition 8.54. Fix a point $\xi \in \partial_{\infty} T$ and a pair of distinct points $z^{+}, z^{+} \in \partial_{\infty} X_{v}$ such that $\left\{z^{+}, z^{+}\right\} \in \Lambda^{\xi}\left(X_{v}, X\right)$. Let $L_{v}=\alpha \subset X_{v}$ be a biinfinite geodesic asymptotic to the points $z^{ \pm}$.
(1) For all vertices and edges $t$ in the ray $v \xi$ we have

$$
F l_{t}\left(\left\{z^{ \pm}\right\}\right)=\left\{z_{t}^{ \pm}\right\} \neq \emptyset
$$

(2) For each vertex/edge $t$ in the ray $v \xi$ let $L_{t}$ be a biinfinite geodesic in $X_{t}$ connecting the points $z_{t}^{ \pm}$. Then the collection of such geodesics forms the union of vertex/edge sets of a metric bundle $\mathfrak{P}=(\pi: L \rightarrow v \xi) \subset \mathfrak{X}$ over $v \xi$, which is also a $K^{\prime}$-ladder for some $K^{\prime}$.
(3) There are constants $K_{1}, C_{1}$ such that for each $n$, the segment $\alpha_{-n, n}=[\alpha(-n) \alpha(n)]_{X_{v}}$ bounds a $\left(K_{1}, C_{1}\right)$-narrow carpet $\mathfrak{B}^{n} \subset \mathfrak{L}$, where $\Lambda$ is the ladder from (2).
(4) Every qi section over $v \xi$ contained in $L$ is asymptotic to $z=\partial_{X_{v}, X}\left(z^{-}\right)=\partial_{X_{v}, X}\left(z^{+}\right) \in$ $\partial_{\infty} X$. In particular, any two such qi sections are at a finite Hausdorff distance from each other.
(5) $\partial_{\infty} L$ is the singleton $\{z\}$, in particular, $\partial_{\infty}(L, X)=\{z\}$.

Proof. We let $\mathfrak{Y}=(\pi: Y \rightarrow v \xi)$ denote the restriction of $\mathfrak{X}$ to the ray $\nu \xi$. We will need:

Lemma 8.55. $\partial_{X_{v}, Y}\left(z^{+}\right)=\partial_{X_{v}, Y}\left(z^{-}\right)$.
Proof. We consider a sequence of $(K, C)$-narrow carpets $\mathfrak{A}^{n}=\mathfrak{A}\left(\alpha_{-n, n}\right)=\left(\pi: A^{n} \rightarrow\right.$ $\left.\llbracket v, w_{n} \rrbracket\right)$ in $\mathfrak{X}$ given by Theorem $8.50(1)$ and bounded by the intervals

$$
\alpha_{-n, n}=[\alpha(-n) \alpha(n)]_{X_{u}} \subset \alpha
$$

Set

$$
\llbracket v, v_{n} \rrbracket=v \xi \cap \llbracket v, w_{n} \rrbracket .
$$

i. Let us first verify that $\lim _{n \rightarrow \infty} v_{n}=\xi$. Suppose not. After passing to a subsequence, the the sequence $\left(v_{n}\right)$ would have to be constant. For sufficiently large each $n$, there is a
point $x_{n}$ in the narrow end of $\mathfrak{A}^{n}$ and a $K$-section $\gamma_{x_{n}}$ in $A^{n}$ connecting $x_{n}$ to $\gamma(v)$. The concatenation $\gamma_{x_{n}} \star \gamma$ is then a uniform quasigeodesic in $X$ (since $v_{n}$ is fixed). But then $\lim _{n \rightarrow \infty} x_{n} \neq \gamma(\infty)$ in $\partial_{\infty} X$, contradicting the assumption that $\left\{z^{+}, z^{-}\right\} \in \Lambda^{\xi}\left(X_{v}, X\right)$.
ii. The carpets $\mathfrak{A}^{n}$ define uniform quasigeodesics $c_{-n, n}$ in $X$ connecting points $\alpha( \pm n)$ (see the proof of Theorem 8.50). Applying the cut-and-replace procedure to the paths $c_{-n, n}$ with respect to the subtree of spaces $Y \subset X$, we obtain uniform quasigeodesics $\hat{c}_{-n, n}$ in $Y$ which project to the intervals $\llbracket v, v_{n} \rrbracket$. Since $\lim _{n \rightarrow \infty} d_{T}\left(v, v_{n}\right)=\infty$, it follows that

$$
d_{Y}\left(\alpha(0), \hat{c}_{-n, n}\right)=\infty,
$$

implying that $\partial_{X_{v}, Y}\left(z^{+}\right)=\partial_{X_{v}, Y}\left(z^{-}\right)$.
We now begin the proof of the proposition. In view of the lemma, we can replace $\mathfrak{X}$ with $\mathfrak{Y}$.
(1) Since $\partial_{X_{v}, Y}\left(z^{+}\right)=\partial_{X_{v}, Y}\left(z^{-}\right)$, Theorem 8.50(1) implies that for each $n>0$ the interval

$$
\alpha_{-n, n}=[\alpha(-n) \alpha(n)]_{X_{u}} \subset \alpha
$$

bounds a $(K, C)$-narrow carpet $\mathfrak{M}^{n}=\mathfrak{A}\left(\alpha_{-n, n}\right)=\left(\pi: A^{n} \rightarrow \llbracket v, w_{n} \rrbracket\right)$ in $\mathfrak{Y}$ for some $K, C$ depending only on the parameters of $\mathfrak{X}, w_{n} \in v \xi$. Since for each vertex $t \in v \xi$

$$
\operatorname{Hd}_{Y}\left(A_{v}^{n}, A_{t}^{n}\right) \leq K d_{T}(v, t),
$$

it follows that the entire geodesic $L_{v}$ is contained in the $K d_{T}(v, t)$-neighborhood of the vertex-space $X_{t}$. Lemma 3.35 now implies that

$$
F l_{t}\left(\left\{z^{ \pm}\right\}\right)=\left\{z_{t}^{ \pm}\right\} \neq \emptyset
$$

This proves (1).
(2) By the construction, for each pair of vertices $s, t \in v \xi$ with $d_{T}(s, t)=1$, the geodesics $L_{s}, L_{t}$ are asymptotic to the same pair of points in $X_{s t}$. Therefore, $\operatorname{Hd}\left(L_{s}, L_{t}\right) \leq D$ for some $D$ depending only on $L_{0}^{\prime}$ and the hyperbolicity constant $\delta_{0}^{\prime}$ of $X_{s t}$. The same applies to the geodesic $L_{e} \subset X_{e}, e=[s, t]$. This proves that the union of $L_{t}$ 's, $t \in V(v \xi), L_{e}$ 's, $e \in E(v \xi)$ forms a metric bundle $\mathfrak{Z}$ in $\mathfrak{Y}$. This metric bundle has structure of a $K^{\prime}$-ladder according to Lemma 3.17.
(3) As noted in the proof of (1), we already have the carpets $\mathfrak{X}^{n}$ in $\mathfrak{Y}$ bounded by the segments $\alpha_{-n, n}$. The trouble is that these carpets need not be contained in the ladder $\mathfrak{Q}$. However, according to Theorem 3.3, there is a uniformly coarse Lipschitz projection $v: \mathfrak{Y} \rightarrow \mathfrak{L}$ which, for every vertex $t \in v \xi$, equals to the restriction of the nearest-point projection $P_{X_{t}, L_{t}}$. Taking the corresponding modified projection $\bar{P}_{X_{t}, L_{t}}\left(A_{t}^{n}\right)$ (see Definition 1.121) we then obtain a collection of subsegments $B_{t}^{n} \subset L_{t}$ satisfying axioms of a $\left(K_{1}, C_{1}\right)$ narrow carpet over $\llbracket v, w_{n} \rrbracket$, which we denote $\mathfrak{B}^{n}$.
(4) Suppose that $\gamma$ is a $k$-qi section of $\mathbb{Z}$ over the ray $v \xi, p=\gamma(v) \in \alpha$. Then $p$ belongs to the segment $\alpha_{-n, n}$ for all sufficiently large $n \geq n_{p}$. We let $c_{n}$ denote the uniform quasigeodesic in $Y$ connecting the end-points of $\alpha_{-n, n}$ and equal to the concatenation of the two horizontal boundary sections of $\mathfrak{B}^{n}$ along with its narrow end (the vertical geodesic segment in $X_{w_{n}}$ ). Since both sequences $(\alpha(n)),(\alpha(-n))$ converge to the same point $z \in \partial_{\infty} Y$, it follows that the sequence of quasigeodesics $\left(c_{n}\right)$ also converges to $z$. For each $n \geq n_{p}$, there exists a vertex $v_{n} \in \llbracket v, w_{n} \rrbracket$ such that

$$
d_{X_{v_{n}}}\left(\gamma\left(v_{n}\right), x_{n}\right) \leq K_{1}+K^{\prime},
$$

where $x_{n}$ lies in $c_{n}$. Clearly,

$$
\lim _{n \rightarrow \infty} d_{Y}\left(\alpha(0), x_{n}\right)=\infty
$$

In particular, the sequence $\left(x_{n}\right)$ converges to $\gamma(\infty)$. Since the sequence $\left(x_{n}\right)$ also converges to $z$, we obtain $\gamma(\infty)=z$.
(5) The proof of this part is similar to that of (4). Consider a geodesic ray $\beta$ in $L$, $\beta(0)=\alpha(0)=p$. Then for each $n$, there is a point $x_{n}$ in $\beta$ within distance $K^{\prime}$ from the path $c_{n}$ in $\mathfrak{B}^{n}$ defined as in the proof of (4). Again, $d\left(p, x_{n}\right) \rightarrow \infty$ and, hence, $\beta(\infty)=$ $\lim _{n \rightarrow \infty} c_{n}=z$.

We now can relate boundary flows to CT-laminations:
Proposition 8.56. Suppose that $\mathfrak{X}=(\pi: X \rightarrow T)$ is a tree of hyperbolic spaces with hyperbolic total space $X, \mathfrak{Y})=(\pi: Y \rightarrow S) \subset \mathfrak{X}$ is a subtree of spaces and $v \in V(S)$ satisfies the following conditions:

1. $\partial_{\infty} X_{w} \subset F l\left(\partial_{\infty} X_{v}\right)$ for each vertex $w \in V(S)$.
2. $\partial_{X_{v}, X}\left(\partial_{\infty} X_{v}\right)=\partial_{\infty} X$.

Then the CT-map $\partial_{X_{v}, Y}: \partial_{\infty} X_{v} \rightarrow \partial_{\infty} Y$ is also surjective.
Proof. We claim that each $z \in \partial_{\infty} Y$ belongs to $\partial_{X_{v}, Y}\left(X_{v}\right)$. Since $\partial_{X_{v}, X}$ is surjective, there is $z_{1} \in \partial_{\infty} X_{v}$ such that $\partial_{X_{v}, X}\left(z_{1}\right)=\partial_{Y, X} \circ \partial_{X_{v}, Y}\left(z_{1}\right)=\partial_{Y, X}(z)$. Thus, for $z^{\prime}=\partial_{X_{v}, Y}\left(z_{1}\right) \in$ $\partial_{\infty} Y, \partial_{Y, X}\left(z^{\prime}\right)=\partial_{Y, X}(z)$.

If $z^{\prime}=z$, then we are done. If not, then by the description of the fibers of the CT-map $\partial_{Y, X}$ given in Proposition 8.47, there exists a vertex-space $X_{w} \subset Y$ such that a geodesic $\beta=z z^{\prime} \subset Y$ asymptotic to $z, z^{\prime}$ is Hausdorff-close to a geodesic $\alpha \subset X_{w}$. In particular, $z \in \partial_{\infty}\left(X_{w}, Y\right)$. The first assumption of the proposition implies that $z \in \partial_{\infty}\left(X_{v}, Y\right)$. Since $\partial_{\infty}\left(X_{v}, Y\right)=\partial_{X_{v}, Y}\left(\partial_{\infty} X_{v}\right)$ (see Lemma 8.5), the claim follows.

### 8.9. Cannon-Thurston lamination and ending laminations

In this section we shall significantly expand on Theorem $8.50(1)$; many of our results are generalizations of the ones proven by Mitra in [Mit97]. Throughout this section we will assume that $\mathfrak{X}=(\pi: X \rightarrow T)$ is a tree of hyperbolic spaces with proper hyperbolic total space $X$.

To motivate the discussion, we recall Thurston's notion of the ending laminations in the setting of hyperbolic 3-manifolds. (We refer the reader for a detailed overview of endinvariants of hyperbolic 3-manifolds to Minsky's surveys [Min03b] and [Min03a].) For simplicity of the discussion, we consider a noncompact complete connected hyperbolic 3-manifold $M$ with finitely-generated fundamental group that does not split as a nontrivial free product and such that $M$ has positive injectivity radius. The manifold $M$ contains a (unique up to isotopy) compact submanifold with smooth boundary $M_{c}$ (the compact core of $M$ ), such that the complement $M \backslash \operatorname{int}\left(M_{c}\right)$ is homeomorphic to $\partial M_{c} \times \mathbb{R}_{+}$. The group $G=\pi_{1}\left(M_{c}\right) \cong \pi_{1}(M)$ is hyperbolic and the assumption that it does not split as a free product implies that for each surface component $S \subset \partial M_{c}$, the inclusion map $S \rightarrow M_{c}$ is $\pi_{1}$-injective.

Each component $E=S \times \mathbb{R}_{+}$of $M \backslash M_{c}$ is an end of $M$; the surface $S$ is a component of $\partial M_{c}$; it is a compact surface which admits a hyperbolic metric (which we fix from now on). For each end $E=S \times \mathbb{R}_{+}$one defines an ending lamination $\lambda=\lambda(E)$ of $E$, which is a certain nonempty compact subset of $S$, equal to a disjoint union of complete geodesics in $S$. Lifting $\lambda$ to the universal covering space of $S$, one obtains a $\pi_{1}(S)$-invariant closed subset of $\tilde{S} \cong \mathbb{H}^{2}$ equal to the disjoint union of geodesics. Each geodesic $\beta$ in $\tilde{\lambda}$ is uniquely determined by an unordered pair $\left\{\xi^{+}, \xi^{-}\right\} \in \partial_{\infty}^{(2)} \mathbb{H}^{2}$, the ideal boundary points such that $\beta=$ $\xi^{-} \xi^{+}$. We, thus, identity $\lambda$ with a $\pi_{1}(S)$-invariant closed subset of $\partial_{\infty}^{(2)} \mathbb{H}^{2}$ consisting of such pairs. Consider a component $\tilde{E}$ of the preimage of $E$ in $\mathbb{H}^{3}$ (the universal covering space
of $M$ ); the boundary surface $\tilde{S}$ of $\tilde{E}$ is a copy of the universal covering space of $S$. It was proven by Minsky [Min94] (under the above assumption on the injectivity radius of $M$ ) and $\mathbf{M j}[\mathbf{M j 1 7}]$ in full generality, that each inclusion map $\tilde{S} \rightarrow \tilde{E}$ has a CT-map; these CT-maps combine in a CT-map for the inclusion $\tilde{M}_{c} \rightarrow \tilde{M}=\mathbb{H}^{3}$ (where $\tilde{M}_{c}$ is the universal covering space of $M_{c}$ equipped with the pull-back Riemannian metric). Each ending lamination $\lambda(E)$ is $\pi_{1}(S)$-equivariantly homeomorphic to the CT-lamination $\Lambda(\tilde{S}, \tilde{E})$ and the union of $G$-orbits of these laminations in $\partial_{\infty} \tilde{M}_{c}$ is the CT-lamination $\Lambda\left(\tilde{M}_{c}, \mathbb{H}^{3}\right)$.

We now relate this discussion to trees of spaces. For each end $E$, the space $\tilde{E}$ (with its intrinsic Riemannian path-metric) is $\pi_{1}(E)$-equivariantly quasiisometric to the total space of a certain metric bundle $\mathfrak{X}_{E}=\left(E \rightarrow \mathbb{R}_{+}\right)$, with vertex and edge-spaces isometric to the hyperbolic plane. (This bundle structure is implicit in [Min94]. It is obtained via pull-back of the universal bundles over the Teichmüller spaces of boundary surfaces of $M_{c}$.) Putting these spaces together, we obtain a tree of spaces $\mathfrak{X}=(X \rightarrow T)$ (on which $G=\pi_{1}(M)$ is acting) which has a distinguished vertex $v$ fixed by $G$. The total space $X$ of $\mathfrak{X}$ is isometric to $\mathbb{H}^{3}$. The tree $T$ is a union of geodesic rays; the intersection of any two distinct rays in this collection is the vertex $v$. Thus, the $G$-orbits of ending laminations $\lambda(E)$ in $\partial_{\infty}^{(2)} G$ can be described as CT-laminations

$$
\Lambda\left(X_{v}, X_{\nu \xi}\right) \subset \partial_{\infty}^{(2)} X_{v}
$$

where, $\xi$ 's are the ideal boundary points of $T$ and $X_{\nu \xi}$ is the total space of the pull-back of $\mathfrak{X}$ to the ray $\nu \xi$ in $T$. The result stated above, relating ending laminations of $M$ with the CT-lamination $\Lambda\left(\tilde{M}_{c}, \mathbb{H}^{3}\right)$ can then be restated as:

$$
\Lambda\left(X_{v}, X\right)=\bigcup_{\xi \in \partial_{\infty} T} \Lambda\left(X_{v}, X_{v \xi}\right) .
$$

In the context of general trees of hyperbolic spaces, points at infinity $\xi \in \partial_{\infty} T$ play the role of ends of the hyperbolic manifolds and, accordingly, ending laminations are defined as CT-laminations $\Lambda\left(X_{v}, X_{v \xi}\right)$. The main goal of this section is to prove an analogue (actually, a sharper version) of the above equality in the setting of more general trees of spaces, Theorem 8.60 below. In particular, we will also prove that for each $\xi \in \partial_{\infty} T$, the ending lamination $\Lambda\left(X_{v}, X_{v \xi}\right)$ equals the subset $\Lambda^{\xi}\left(X_{v}, X\right) \subset \Lambda\left(X_{v}, X\right)$ defined in the previous section. This alternative interpretation of the ending lamination $\Lambda\left(X_{v}, X_{\nu \xi}\right)$ will be used in several places, e.g. proof of Theorem 8.60, Parts (4) and (5) and proof of Proposition 8.64.

The results below are motivated by similar results obtained in [KS20, section 6.2]; our notation and proofs are similar (see also [Mit97, Bow13]).

Lemma 8.57. Suppose that $\mathfrak{X}=(\pi: X \rightarrow T)$ is a tree of hyperbolic spaces with proper hyperbolic total space $X$. We fix a vertex $v \in V(T)$ and $K \geq 1$.

1. For every $\xi \in \partial_{\infty} T$, there is a geodesic ray $\rho$ joining $v$ to $\xi$.
2. There is $K_{1}$ depending on $K$ and the parameters of $\mathfrak{X}$ such that the following holds. Let $\left(w_{n}\right)$ be a sequence of points in $V(T) \cup \partial_{\infty} T$ and let $\left(\gamma_{n}\right)$ be a sequence of $K$-qi sections of $\mathfrak{X}$ of over the geodesic $v w_{n}$. Suppose that the sequence $\left(\gamma_{n}(v)\right)$ belongs to a bounded subset $B$ of $X$ and the sequence $\left(\gamma_{n}\left(w_{n}\right)\right)$ converges to a point $\eta \in \partial_{\infty} X$. Then the sequence $\left(w_{n}\right)$ converges to a point $\xi \in \partial_{\infty} T$ and there is a $K_{1}$-qi section $\gamma$ over the geodesic $v \xi$ such that $\eta=\gamma(\infty)$ and $\gamma(v) \in B$.

Proof. 1. Let ( $w_{n}$ ) be a Gromov-sequence of vertices in $T$ representing the point $\xi$. Then

$$
\lim _{m, n \rightarrow \infty} d_{T}\left(v, w_{m} w_{n}\right)=\infty
$$

It follows that the union of geodesic segments $v w_{n}, n \in \mathbb{N}$, is a locally finite subtree $S \subset T$. Therefore, the sequence of segments $v w_{n}$ subconverges to a geodesic ray $\rho$ in $S$ emanating from $v$. In order to prove that $\rho$ joins $v$ to $\xi$ we note that for each $m \in \mathbb{N}$ and all sufficiently large $n$, the points $t_{m}=\rho(m)$ satisfy

$$
d_{T}\left(v, t_{m} w_{n}\right)=d_{T}\left(v, t_{m}\right)=m .
$$

Thus, the sequence $\left(t_{m}\right)$ is a Gromov-sequence equivalent to $\left(w_{n}\right)$.
2. Pick a base-point $x_{0}$ in a bounded subset $B \subset X$ of diameter $D$ containing all the points $\gamma_{n}(v)$, e.g. we can take $x_{0}=\gamma_{1}(v)$.

Since the sequence $\left(\gamma_{n}\left(w_{n}\right)\right)$ converges $\eta \in \partial_{\infty} X$, we have

$$
\lim _{n \rightarrow \infty} d_{T}\left(v, w_{n}\right)=\infty
$$

Moreover, since the sequence of geodesic segments $\gamma_{i}^{*}=\left[x_{0} \gamma_{n}\left(w_{n}\right)\right]_{X}$ coarsely converges to a geodesic ray $x_{0} \xi$ (see [DK18, Definition 8.32]), there is a constant $C$ (depending only on $K, D$ and the hyperbolicity constant of $X$ ) such that for each $R$, there is a number $n_{0}$ such that for all $m, n \geq n_{0}$ the Hausdorff-distance between $\gamma_{m} \cap B\left(x_{0}, R\right)$ and $\gamma_{n} \cap B\left(x_{0}, R\right)$ is $\leq C$. Since $\gamma_{i}$ 's are sections over geodesic segments $v w_{i}$ in $T$, it follows that

$$
\lim _{i \rightarrow \infty} \sup \left\{R: v w_{m} \cap B(v, R)=v w_{n} \cap B(v, R) \forall m, n \geq i\right\}=\infty .
$$

In particular, $\left(w_{n}\right)$ is a Gromov-sequence in $T$ converging to some $\xi \in \partial_{\infty} T$ and by Part 1 of the lemma, the sequence of segments $\left(\nu w_{n}\right)$ converges to the ray $v \xi$.

Furthermore, in view of properness of $X$, the sequence of $K$-qi sections $\left(\gamma_{n}\right)$ subconverges to a $K$-qi section $\gamma$ over the geodesic ray $v \xi$ in $T$ (this is a coarse version of the Arzela-Ascoli Theorem, cf. [DK18, Proposition 8.34]).

Fix $K \geq K_{0}$, pick a vertex $v \in V(T)$ and let $\mathfrak{V}=(\pi: Y \rightarrow S)$ be a $(K, D, E, \lambda)$ semicontinuous family in $\mathfrak{X}$ relative to a vertex $v \in S \subset T$, see Definiton 3.1. The following proposition is motivated by the results of [KS20] and [Bow13, Proposition 8.2]:

Proposition 8.58. We have

$$
\partial_{\infty} Y=U:=\partial_{\infty}\left(X_{v}, Y\right) \cup\left(\bigcup_{\xi \in \partial_{\infty} S} \partial_{\infty}^{\xi}\left(X_{v}, X\right)\right) .
$$

Proof. Recall that, according to Theorem 3.3, $Y$ is qi embedded in $X$. Thus, we will identify $\partial_{\infty} Y$ with a subset of $\partial_{\infty} X$. Since $U$ is obviously contained in $\partial_{\infty} Y$, we only have to prove that every point $z \in \partial_{\infty} Y$ lies in $U$. Fix a base-point $x \in X_{v}$. Suppose that $x_{n} \in Y_{v_{n}}$ is a sequence of points converging to $z$. Let $\gamma_{n}$ be a $K$-qi section in $Y$ over $v v_{n}$, joining $x_{n}$ to $y_{n} \in Y_{v}$.
(i) Suppose first that $\left(y_{n}\right)$ is a bounded sequence. Then by Lemma 8.57(2), the sequence $\left(v_{n}\right)$ converges to some $\xi \in \partial_{\infty} T_{v}$ and the sequence $\left(\gamma_{n}\right)$ coarsely converges to a $K$ qi section $\gamma$ in $Y$ over the ray $v \xi$, so that $x_{n} \rightarrow \gamma(\infty)$. Thus $z=\lim _{n \rightarrow \infty} x_{n} \in \partial_{\infty}^{\xi}\left(X_{v}, X\right) \subset U$ in this case.
(ii) Consider now the case when $\left(y_{n}\right)$ is an unbounded sequence. After extraction, we can assume that $\left(y_{n}\right)$ converges to some $z^{\prime} \in \partial_{\infty}\left(X_{v}, X\right)=\partial_{\infty}\left(X_{v}, Y\right)$ (since $Y$ is quasiconvex in $X$ ). We claim that $z^{\prime}=z$. Since each $\gamma_{n}$ is a $K$-qi section, it suffices to show that $d\left(x, \gamma_{n}\right) \rightarrow \infty$. Suppose that the sequence $d\left(x, \gamma_{n}\right)$ is bounded, and $p_{n}=$ $\gamma_{n}\left(v_{n}\right), v_{n} \in V\left(\llbracket v, \pi\left(y_{n}\right) \rrbracket\right)$, is a sequence such that $d_{X}\left(x, p_{n}\right) \leq C$ for all $n$. Since $d_{T}\left(v, v_{n}\right)=$ $d_{T}\left(\pi(x), \pi\left(p_{n}\right)\right) \leq d_{X}\left(x, p_{n}\right) \leq C$, it follows that

$$
d_{X}\left(y_{n}, p_{n}\right) \leq C K, d_{X}\left(x, y_{n}\right) \leq C+C K,
$$

contradicting the assumption that the sequence $\left(y_{n}\right)$ is unbounded. Thus,

$$
z=z^{\prime} \in \partial_{\infty}\left(X_{v}, Y\right) \subset U
$$

Corollary 8.59. For any ladder $\mathfrak{L}=(\pi: L \rightarrow \pi(L))$ in $\mathfrak{X}$, centered at a vertex $v \in V(T)$, we have

$$
\partial_{\infty}(L, X)=\bigcup_{\xi \in \partial_{\infty} \pi(L)} \partial_{\infty}^{\xi}\left(L_{v}, X\right)
$$

Proof. Since $L_{v}$ is a finite geodesic segment, $\partial_{\infty}\left(L_{v}, L\right)=\emptyset$, and, thus, the corollary is an immediate consequence of Proposition 8.58.

We now return to the discussion of properties of ending laminations $\Lambda\left(X_{v}, X_{x \xi}\right)$ and their relation to the CT-laminations $\Lambda\left(X_{v}, X\right)$ and their subsets $\Lambda^{\xi}\left(X_{v}, X\right)$ defined in the previous section (see Definition 8.53).

Theorem 8.60 (Properties of ending laminations). Suppose that $X=(\pi: X \rightarrow T)$ is a tree of hyperbolic spaces with hyperbolic and proper total space $X$. There exists $K$ depending only of the parameters of $\mathfrak{X}$ and the hyperbolicity constant of $X$ such that the following hold:
(1) Let $v$ be a vertex of $T$ and let $\alpha: \mathbb{R} \rightarrow X_{v}$ be a complete geodesic in $X_{v}$ such that $\{\alpha(-\infty), \alpha(\infty)\} \in \Lambda\left(X_{v}, X\right)$. Then for both $z \in\{\alpha( \pm \infty)\}$, there exists point $\xi \in \partial_{\infty} T_{z}$ such that for each $p \in \alpha$, there is a $K$-qi section $\gamma$ over $v \xi$ satisfying $\gamma(v)=p$ and $\gamma(\infty)=\partial_{X_{v}, X}(\alpha(\infty))$. In other words, for each point $\left\{z^{-}, z^{+}\right\} \in$ $\Lambda\left(X_{v}, X\right)$, there exists $\xi \in \partial_{\infty} T$ such that

$$
\partial_{X_{v}, X}\left(z^{ \pm}\right) \in \Lambda^{\xi}\left(X_{v}, X\right)
$$

and, thus,

$$
\Lambda\left(X_{v}, X\right)=\bigcup_{\xi \in \partial_{\infty} T_{v}} \Lambda^{\xi}\left(X_{v}, X\right) .
$$

(2) For each $\xi \in \partial_{\infty} T$ we have

$$
\Lambda^{\xi}\left(X_{v}, X\right)=\Lambda\left(X_{v}, X_{v \xi}\right)=\Lambda\left(X_{v}, F l_{K}\left(X_{v}\right) \cap X_{v \xi}\right)
$$

(3) Each $\Lambda^{\xi}\left(X_{\nu}, X\right)$ is a closed subset of $\partial_{\infty}^{(2)} X_{v}$.
(4) Suppose $\xi_{1} \neq \xi_{2} \in \partial_{\infty} T$, and $\alpha_{1}, \alpha_{2}$ complete geodesics in $X_{v}$ such that $\left\{z_{i}^{-}, z_{i}^{+}\right\}=$ $\left\{\alpha_{i}(-\infty), \alpha_{i}(\infty)\right\} \in \Lambda^{\xi_{i}}\left(X_{v}, X\right), i=1,2$. Then the subsets $\left\{z_{1}^{-}, z_{1}^{+}\right\},\left\{z_{2}^{-}, z_{2}^{+}\right\}$of $\partial_{\infty} X_{v}$ are disjoint. In particular, the ending laminations $\Lambda^{\xi_{1}}\left(X_{v}, X\right), \Lambda^{\xi_{2}}\left(X_{v}, X\right)$ are disjoint and the point $\xi$ in (1) is uniquely determined by $\left\{z^{-}, z^{+}\right\} \in \Lambda\left(X_{v}, X\right)$.
(5) Ending laminations $\Lambda^{\xi}$ depend upper semicontinuously ${ }^{3}$ on $\xi$ : Suppose that $\xi_{n} \rightarrow$ $\xi$ in $\partial_{\infty} T_{v},\left\{z_{n}^{+}, z_{n}^{-}\right\} \in \Lambda^{\xi_{n}}\left(X_{v}, X\right)$ and $\left\{z_{n}^{+}, z_{n}^{-}\right\} \rightarrow\left\{z^{+}, z^{-}\right\} \in \partial_{\infty}^{(2)} X_{v}$. Then $\left\{z^{+}, z^{-}\right\} \in$ $\Lambda^{\xi}\left(X_{v}, X\right)$.
(6) If $\xi_{1} \neq \xi_{2} \in \partial_{\infty} T_{v}$, then any two leaves $\alpha^{i}$ of $\Lambda^{\xi_{i}}\left(X_{v}, X\right), i=1,2$, are uniformly cobounded in $X_{v}$. Namely, given $D>0$ there exists $R=R(D)$ (independent of $\alpha^{1}, \alpha^{2}$ but possibly depending on $\left.\xi_{1}, \xi_{2}\right)$ such that $\alpha^{1} \cap N_{D}\left(\alpha^{2}\right)$ has diameter $\leq R$.

Proof. (1) The proof follows the argument in the proof of Proposition 8.54(1) (or Part (3) of that proposition). By Theorem $8.50(1)$, for each $n>0$ the interval

$$
\alpha_{-n, n}=[\alpha(-n) \alpha(n)]_{X_{u}} \subset \alpha
$$

bounds a $(K, C)$-narrow carpet $\mathfrak{A}^{n}=\mathfrak{A}\left(\alpha_{-n, n}\right)$ in $X$, which, in turn, defines a uniform quasigeodesic $c_{n}=c\left(\mathfrak{A}^{n}\right)$ in $\mathfrak{A}\left(\alpha_{-n, n}\right)$ connecting the points $\alpha(-n), \alpha(n)$. Take any point

[^15]$p \in \alpha$. Then for all $n \geq n_{p}, p$ belongs to the segment $\alpha_{-n, n}$. Since $\mathfrak{A}^{n}$ is a $K$-metric bundle, there exists a $K$-section $\gamma^{n}$ over the segment $\llbracket v, w_{n} \rrbracket=\pi\left(A^{n}\right)$. The end-point $x_{n}=\gamma^{n}\left(w_{n}\right)$ belongs to $c_{n}$, which implies that the sequence $\left(x_{n}\right)$ converges to the limit point $\partial_{X_{v}, X}(\alpha(-\infty))=\partial_{X_{v}, X}(\alpha(\infty))$. Then the existence of the point $\xi$ follows from Lemma 8.57(2): Proposition 8.54(1) implies that $\xi \in \partial_{\infty} T_{z}, z=\alpha( \pm \infty)$. The rest of the assertions of Part (1) follow immediately from the definition of $\Lambda^{\xi}\left(X_{v}, X\right)$.
(2) The inclusion $\Lambda^{\xi}\left(X_{v}, X\right) \subset \Lambda\left(X_{v}, X_{v \xi}\right)$ is clear from the definition of $\Lambda^{\xi}\left(X_{v}, X\right)$. The opposite inclusion is a direct consequence of Part (1) of the theorem. The inclusion $\Lambda\left(X_{v}, F l_{K}\left(X_{v}\right) \cap X_{v \xi}\right) \subset \Lambda\left(X_{v}, X_{v \xi}\right)$ for every $K \geq K_{0}$ is clear from the fact that $F l_{K}\left(X_{v}\right)$ is quasiconvex in $X$. Suppose that $\left\{z^{-}, z^{+}\right\} \in \Lambda\left(X_{v}, X_{v \xi}\right)$. Proposition 8.54(1) implies that for each vertex $t \in v \xi, F l_{t}\left(\left\{z^{ \pm}\right\}\right) \neq \emptyset$. By Lemma 3.37(1), there exists $K$ such that for each vertex/edge $t$ in $v \xi$ there exists a biinfinite geodesic $L_{t} \subset F l_{K}\left(X_{v}\right)$ asymptotic to the points $F l_{t}\left(\left\{z^{ \pm}\right\}\right)$. By Proposition 8.54(2), these geodesics form a ladder $\mathfrak{L}=(\pi: L \rightarrow v \xi)$ in $X$. By Part 5 of the same proposition, $\partial_{\infty} L$ is a singleton, which implies
$$
\partial_{X_{v}, F l_{K}\left(X_{v}\right) \cap X_{v \xi}}\left(z^{+}\right)=\partial_{X_{v}, F l_{K}\left(X_{v}\right) \cap X_{v \xi}}\left(z^{-}\right) .
$$

In other words,

$$
\left\{z^{-}, z^{+}\right\} \in \Lambda\left(X_{v}, F l_{K}\left(X_{v}\right) \cap X_{v \xi}\right) .
$$

(3) In view of Part (2), the claim follows from the fact that the CT-lamination $\Lambda\left(X_{v}, X_{\nu \xi}\right)$ is closed in $\partial_{\infty}^{(2)} X_{v}$.
(4) By Proposition $8.54(2)$ and (4) there are qi sections $\gamma_{i}$ over $v \xi_{i}$ asymptotic to $\partial_{X_{v}, X}\left(z_{i}^{ \pm}\right), i=1,2$. Since $\xi_{1} \neq \xi_{2}, \operatorname{Hd}\left(v \xi_{1}, v \xi_{2}\right)=\infty$, which, in turn, implies that $\operatorname{Hd}\left(\gamma_{1}, \gamma_{2}\right)=$ $\infty$. Thus $\gamma_{1}(\infty) \neq \gamma_{2}(\infty)$, whence $\left\{z_{1}^{-}, z_{1}^{+}\right\} \cap\left\{z_{2}^{-}, z_{2}^{+}\right\}=\emptyset$.
(5) Since $\partial_{X_{v}, X}\left(z_{n}^{+}\right)=\partial_{X_{v}, X}\left(z_{n}^{-}\right)$and $\partial_{X_{v}, X}$ is continuous, we have $\partial_{X_{v}, X}\left(z^{+}\right)=\partial_{X_{v}, X}\left(z^{-}\right)$. Thus $\left\{z^{+}, z^{-}\right\} \in \Lambda\left(X_{v}, X\right)$. Since $z^{+} \neq z^{-}$, geodesics $\alpha_{n}$ in $X_{v}$ connecting the points $z_{n}^{ \pm}$all intersect a certain bounded subset of $X_{v}$. Hence, we can parameterize these geodesics so that the sequence $\left(\alpha_{n}(0)\right)$ is bounded in $X_{v}$. In view of properness of $X_{v}$, by the ArzelaAscoli theorem, the sequence of geodesics $\alpha_{n}$ subconverges to a geodesic $\alpha$ in $X$. This geodesic is necessarily asymptotic to the points $z^{ \pm}$, see e.g. [DK18, Theorem 11.104]. Since $\left\{z_{n}^{+}, z_{n}^{-}\right\}$belongs to $\Lambda^{\xi}\left(X_{v}, X\right)$, there exist uniform qi sections $\gamma_{n}$ over $v \xi_{n}$ connecting $\alpha_{n}(0)$ to $\partial_{X_{v}, X}\left(z^{ \pm}\right)$. By the continuity of the CT-map, $z_{n} \rightarrow z$ implies that $\partial_{X_{v}, X}\left(z_{n}\right) \rightarrow$ $\partial_{X_{v}, X}(z)$. Accordingly, $\gamma_{n}(\infty) \rightarrow \partial_{X_{v}, X}(z)$. Hence, by Lemma 8.57(2) there is a qi section $\gamma$ over $v \xi$ such that $\gamma(\infty)=\partial_{X_{v}, X}\left(z^{ \pm}\right)$, which implies that $\left\{z^{+}, z^{-}\right\}$belongs to $\Lambda^{\xi}\left(X_{v}, X\right)$.
(6) Note that this statement is a strengthening of Part (4) since that part is equivalent to the statement that the leaves $\alpha^{1}, \alpha^{2}$ are cobounded in $X_{v}$. Note also that, since vertex-spaces of $\mathfrak{X}$ are uniformly properly embedded in $X$, the following two properties are equivalent for subsets $Y^{1}, Y^{2} \subset X_{v}$ :
(i) There exists a function $R_{v}(D)$ such that $\operatorname{diam}_{X_{v}}\left(Y^{1} \cap N_{D}^{X_{v}}\left(Y^{2}\right)\right) \leq R_{v}(D)$.
(ii) There exists a function $R(D)$ such that $\operatorname{diam}_{X}\left(Y^{1} \cap N_{D}\left(Y^{2}\right)\right) \leq R(D)$.

Set $\alpha^{i}( \pm \infty)=z_{i}^{ \pm}, i=1,2$. Let $x_{i}^{ \pm} \in \alpha_{i}, i=1,2$, be points such that

$$
\begin{equation*}
d_{X_{v}}\left(x_{1}^{ \pm}, x_{2}^{ \pm}\right) \leq D . \tag{8.1}
\end{equation*}
$$

Our goal is to get an upper bound (in terms of $D$ ) on the distances $d_{X_{v}}\left(x_{i}^{+}, x_{i}^{-}\right), i=1,2$.
a. We first consider the special case when the rays $v \xi_{1}, v \xi_{2}$ intersect only at the vertex $v$. We have subtrees of spaces $\mathfrak{Y}{ }^{i}=\left(\pi: X_{v \xi_{i}} \rightarrow v \xi_{i}\right)$ in $X, i=1,2$. Since for $i=1,2$,

$$
\left\{z_{i}^{-}, z_{i}^{+}\right\} \in \Lambda^{\xi_{i}}\left(X_{v}, X\right)=\Lambda\left(X_{v}, X_{v \xi_{i}}\right),
$$

there is a sequence of $(K, C)$-narrow carpets

$$
\mathfrak{A}^{i, n}=\mathfrak{A}\left(\alpha_{-n, n}^{i}\right) \subset \mathfrak{Y}^{i}, n \in \mathbb{N},
$$

where $\alpha_{-n, n}^{i}$ is the subinterval in $\alpha^{i}$ between $\alpha^{i}(-n), \alpha^{i}(n)$. In particular, for all sufficiently large $n, x_{i}^{ \pm} \in \alpha_{-n, n}^{i}, i=1,2$. Connect $x_{i}^{ \pm}$to the narrow end of $\mathfrak{A}^{i, n}$ by a $K$-section $\gamma_{i}^{ \pm}$in $\mathfrak{A}^{i, n}$, $i=1,2$. Since $d_{X_{v}}\left(x_{1}^{ \pm}, x_{2}^{ \pm}\right) \leq D$, both concatenations

$$
\phi^{-}:=\gamma_{1}^{-} \star\left[x_{1}^{-} x_{2}^{-}\right]_{X_{v}} \star \gamma_{2}^{-}, \phi^{+}:=\gamma_{1}^{+} \star\left[x_{1}^{+} x_{2}^{+}\right]_{X_{v}} \star \gamma_{2}^{+}
$$

are $k$-quasigeodesics in $X$ with $k$ depending only on $K$ and $D$. The respective end-points of these quasigeodesics are at most $C$-apart from each other. It follows that $d_{X_{v}}\left(x_{i}^{+}, x_{i}^{-}\right) \leq R=$ $R\left(k, \delta_{X}\right)$, cf. Lemmata 1.54 and 2.46.
b. We now consider the general case: The rays $v \xi_{1}, v \xi_{2}$ intersect along a finite subinterval $\nu w$ (this subinterval is finite since $\xi_{1} \neq \xi_{2}$ ). Since $\left\{z_{i}^{-}, z_{i}^{+}\right\} \in \Lambda^{\xi_{i}}\left(X_{v}, X\right)$, there exist vertical geodesics $\beta^{1}, \beta^{2}$ in $X_{w}$ within uniformly bounded (in terms of $d_{T}(v, w)$ ) Hausdorff distance from $\alpha^{1}, \alpha^{2}$ respectively, see Proposition 8.54. By Part (a), the geodesics $\beta^{1}, \beta^{2}$ are uniformly cobounded in $X_{w}$. It follows that $\alpha^{1}, \alpha^{2}$ are uniformly cobounded as well.

Corollary 8.61. For each vertex $v \in T$ and

$$
z \in \partial_{\infty}\left(X_{v}, X\right) \backslash\left(\bigcup_{\xi \in \partial_{\infty} T} \partial_{\infty}^{\xi}\left(X_{v}, X\right)\right)
$$

the preimage $\partial_{X_{v}, X}^{-1}(z)$ is a singleton.
Proof. By Lemma 8.5, $\partial_{\infty}\left(X_{v}, X\right)=\partial_{X_{v}, X}\left(\partial_{\infty} X_{v}\right)$. Thus, all we need is to show that $\left|\partial_{X_{v}, X}^{-1}(z)\right| \leq 1$. As we noted in the previous section, for each $\xi \in \partial_{\infty} T$,

$$
\partial_{X_{v}, X}\left(\Lambda^{\xi}\left(X_{v}, X\right)\right) \subset \partial_{\infty}^{\xi}\left(X_{v}, X\right)
$$

Hence, $z \notin \partial_{X_{v}, X}\left(\Lambda^{\xi}\left(X_{v}, X\right)\right)$ for any $\xi \in \partial_{\infty} T$. However, according to Theorem 8.60(1),

$$
\Lambda\left(X_{v}, X\right)=\bigcup_{\xi \in \partial_{\infty} T_{v}} \Lambda^{\xi}\left(X_{v}, X\right)
$$

which means that there is no $\left\{z^{+}, z^{-}\right\} \in \Lambda\left(X_{v}, X\right)$ satisfying $\partial_{X_{v}, X}\left(z^{ \pm}\right)=z$. Thus, $\partial_{X_{v}, X}^{-1}(z)$ contains at most one point.

Corollary 8.62. 1. If for each $\xi \in \partial_{\infty} T, \Lambda^{\xi}\left(X_{v}, X\right)=\emptyset$, then $\Lambda\left(X_{\nu}, X\right)=\emptyset$, i.e. the CT-map $\partial_{X_{v}, X}$ is 1-1.
2. If $z^{ \pm} \in \partial_{\infty} X_{v}$ are distinct points such that $\partial_{X_{v}, X}\left(z^{+}\right)=\partial_{X_{v}, X}\left(z^{-}\right)$, then there exists $\xi \in \partial_{\infty} T$ such that for every vertex $w \in v \xi, F l_{w}\left(\left\{z^{ \pm}\right\}\right) \neq \emptyset$.

Proof. 1. The first claim is a direct consequence of Theorem 8.60(1).
2. Since $\partial_{X_{v}, X}\left(z^{+}\right)=\partial_{X_{v}, X}\left(z^{-}\right),\left\{z^{+}, z^{-}\right\} \in \Lambda\left(X_{v}, X\right)$. By Theorem 8.60(1), there exists $\xi \in \partial_{\infty} T$ such that $\left\{z^{+}, z^{-}\right\} \in \Lambda^{\xi}\left(X_{v}, X\right)$. Now the claim follows from Proposition 8.54(1).

### 8.10. Conical limit points in trees of hyperbolic spaces

In this section we consider trees of hyperbolic spaces $\mathfrak{X}=(\pi: X \rightarrow T)$ with proper total space $X$ and discuss the relation between conicality for limit points of subtrees of spaces $Y \subset X$ and the CT-maps $\partial_{Y, X}$. Namely, identifying $\Lambda(Y, X)$ with a subset $\Sigma(Y, X)$ of $\partial_{\infty} Y$ equal

$$
\bigcup_{\left\{z^{+}, z^{-}\right\} \in \Lambda(Y, X)}\left\{z^{+}, z^{-}\right\}
$$

we'll see that $\partial_{Y, X}(\Sigma(Y, X))$ is disjoint from the conical limit set of $Y$ in $\partial_{\infty} X$.
The next definition is motivated by the notion of conical limit points of group actions on hyperbolic spaces, see Definition 1.135, as well as Definition 11.93 and Section 11.13.4 in [DK18].

Definition 8.63. Suppose $X$ is an arbitrary hyperbolic geodesic metric space and $Y \subset$ $X$. Then a point $\xi \in \partial_{\infty}(Y, X) \subset \partial_{\infty} X$ is called a conical limit point of $Y$ if for some (any) (quasi)geodesic $\alpha \subset X$ asymptotic to $\xi$ there is $R>0$ and a sequence of points $\left\{y_{n}\right\}$ in $N_{R}(\alpha) \cap Y$ converging to $\xi$. The set of conical limit points of $Y$ is called the conical limit set of $Y$ in $\partial_{\infty} X$.

Thus, if $Y$ is an orbit $G x$ of an isometric proper action $G \curvearrowright X$, then $\xi$ is a conical limit point of $Y$ if and only if it is a conical limit point of the $G$-action on $X$.

Proposition 8.64. Suppose $\mathfrak{X}=(\pi: X \rightarrow T)$ is a tree of hyperbolic spaces with proper and hyperbolic total space, and $\mathfrak{Y}=(\pi: Y \rightarrow S) \subset \mathfrak{X}$ is a subtree of spaces. Let $\partial_{Y, X}: \partial_{\infty} Y \rightarrow \partial_{\infty} X$ be the CT-map. If $\eta \in \partial_{\infty}(Y, X)$ is a conical limit point of $Y$, then $\left|\partial_{Y, X}^{-1}(\eta)\right|=1$.

Proof. If not, then there are distinct points $z_{ \pm} \in \partial_{\infty} Y$ such that $\partial_{Y, X}\left(z_{-}\right)=\partial_{Y, X}\left(z_{+}\right)=\eta$. Consider a geodesic $\beta$ in $Y$ asymptotic to the points $z_{ \pm}$. By Proposition 8.47, there exists a vertex space $X_{v} \subset Y$ and a complete geodesic $\alpha \subset X_{v}$ such that $\operatorname{Hd}(\alpha, \beta)<\infty$. Let $z_{ \pm}^{\prime}=\alpha( \pm \infty)$. It follows that $\partial_{X_{v}, X}\left(z_{ \pm}^{\prime}\right)=\eta$. By Theorem $8.60(1)$, there is a point $\xi \in \partial_{\infty} T$ and a qi section $\gamma$ over the ray $v \xi$, such that $\gamma(\infty)=\eta$. We claim that $\xi \in \partial_{\infty} T \backslash \partial_{\infty} S$. If not, then the ray $\nu \xi$ is contained in the subtree $S$. By Theorem 8.60(2),

$$
\left\{z_{-}^{\prime}, z_{+}^{\prime}\right\} \in \Lambda^{\xi}\left(X_{v}, X\right)=\Lambda\left(X_{v}, X_{v \xi}\right) \subset \Lambda\left(X_{v}, Y\right)
$$

But then $\partial_{X_{v}, Y}\left(z_{ \pm}^{\prime}\right)=z_{ \pm}$and $z_{+}=z_{-}$, contradicting our assumption that the points $z_{ \pm}$ are distinct. It then follows that $\lim _{n \rightarrow \infty} d_{X}(\gamma(n), Y)=\infty$. Since $\gamma(\infty)=\eta$ and $\gamma$ is a quasigeodesic in $X$, this contradicts the hypothesis that $\eta$ is a conical limit point of $Y$ and proves the proposition.

Remark 8.65. This proposition is a geometric counterpart of the following grouptheoretic result: If $H$ is a hyperbolic subgroup of a hyperbolic group $G$, and the CT-map $\partial_{H, G}$ exists, and a limit point $z$ of $H$ in $G$ is conical, then $\left|\partial_{H, G}^{-1}(z)\right|=1$. The converse to this implication is false, see [JKLO16].

The following conjecture is motivated by [KL19]:
Conjecture 8.66. Suppose that $H<G$ is a hyperbolic subgroup of a hyperbolic group, the CT-map $\partial_{H, G}$ exists, but $H$ is not quasiconvex in $G$. Then there is a continuum of (nonconical) limit points of $H$ in $G$ whose preimages under $\partial_{H, G}$ are not singletons.

### 8.11. Group-theoretic applications

In this section we collect group-theoretic applications of our existence results for CTmaps.
8.11.1. Maps to products and examples of undistorted subgroups in $\operatorname{PSL}(2, \mathbb{C}) \times$ $\operatorname{PS} L(2, \mathbb{C})$. Set $H:=\operatorname{PS} L(2, \mathbb{C})$ and $G:=H \times H$. We equip $G$ with a left-invariant Riemannian metric and the corresponding left-invariant distance function $d_{G}$. A finitely generated subgroup $\Gamma<G$ is said to be undistorted if the inclusion map

$$
\left(\Gamma, d_{\Gamma}\right) \rightarrow\left(G, d_{G}\right)
$$

is a qi embedding, where $d_{\Gamma}$ is a word metric on $\Gamma$. Since $G$ acts properly, isometrically and transitively on $\mathbb{H}^{3} \times \mathbb{H}^{3}$, a subgroup $\Gamma<G$ is undistorted if and only if for (some/every) point $x \in \mathbb{H}^{3} \times \mathbb{H}^{3}$ the orbit map $\gamma \mapsto \gamma x$ is a qi embedding of $\Gamma$ (with its word metric) into $\mathbb{H}^{3} \times \mathbb{H}^{3}$.

An element $h \in H$ is called parabolic if it has precisely one fixed point in the Riemann sphere. An element $g=\left(h_{1}, h_{2}\right) \in G$ is called semisimple if neither component $h_{1}$ nor $h_{2}$ is a parabolic element of $H$. We will not attempt to define here Anosov subgroups of $G$, it suffices to say that each Anosov subgroup $\Gamma<G$ is Gromov-hyperbolic and for one of the factors $H_{ \pm}$of $G=H \times H=H_{+} \times H_{-}$, the projection to $\Gamma$ to $H_{ \pm}$has finite kernel and convex-cocompact image. Moreover, each Anosov subgroup is undistorted in $G$. We refer to the reader to [GW12, KL18a, KLP17] for the detailed definitions. O. Guichard constructed in [Gui04] (see also [GGKW17]) an example of an undistorted non-Anosov free subgroup $\Gamma<G$. The subgroup in his example contained non-semisimple elements. (Its projections to both factors were geometrically finite with parabolic elements, we refer the reader to [Bow95] for definitions of geometric finiteness.) Let $S$ be a closed connected oriented hyperbolic surface with the fundamental group $\pi$.

Theorem 8.67. There exists an undistorted subgroup $\Gamma<G$ isomorphic to $\pi$, such that every element of $\Gamma$ is semisimple, but $\Gamma$ is not Anosov.

Proof. Let $c$ be a complete geodesic in the Teichmüller space $T(S)$ of $S$, such that the projection of $c$ to the moduli space of $S$ is bounded. For instance, $c$ can be taken to be the unique invariant geodesic (axis) in $T(S)$ of a pseudo-Anosov homeomorphism $h$ of $S$. The asymptotics of $c$ in positive/negative directions are described by two transversal geodesic laminations $\lambda^{ \pm}$on $S$, called ending laminations: Such laminations contain no closed geodesics and each component of $S \backslash \lambda^{ \pm}$is simply-connected (see [Kla18]). In the example where $c$ is the axis of a pseudo-Anosov homeomorphism $h$, the laminations $\lambda^{ \pm}$ are stable/unstable laminations of $h$ (see e.g. [CB88]).

Take $\lambda^{ \pm}$, the ending laminations of a pseudo-Anosov homeomorphism of $S$ or, more generally, any two transversal ending geodesic laminations on $S$. There exist discrete embeddings $\rho_{ \pm}: \pi \rightarrow H$ such that the image $\Gamma_{ \pm}$of each $\rho_{ \pm}$is a singly-degenerate subgroup of $H$ without parabolic elements such that $\lambda^{ \pm}$is the ending lamination of the geometrically infinite end ${ }^{4} E^{ \pm}$of the hyperbolic manifold $M^{ \pm}=\mathbb{H}^{3} / \Gamma_{ \pm}$. Furthermore, there exists a discrete embedding $\rho_{0}: \pi \rightarrow H$ such that the group $\Gamma_{0}=\rho_{0}(\pi)$ is doubly-degenerate group, whose quotient manifold $M_{0}=\mathbb{H}^{3} / \Gamma_{0}$ has two ends $E_{0}^{ \pm}$with the ending laminations $\lambda^{ \pm}$. We refer the reader to [Ohs09] for proofs of more general existence theorems of this type (which are generalizations of Thurston's double limit theorem). The ends $E^{ \pm}$are bilipschitz homeomorphic to the ends $E_{0}^{ \pm}$of the manifold $M_{0}$ (see [Min94] or [BCM12] for more general results). The manifolds $M_{0}, M^{ \pm}$have injectivity radii bounded from below and $M^{ \pm}$has structure of a metric bundle over $\mathbb{R}$, whose fibers are uniformly bilipschitz to the surface $S$. For instance, in the case when $\lambda^{ \pm}$are stable/unstable laminations of a pseudo-Anosov homeomorphism $h$, the manifold $M_{0}$ is isometric to a cyclic covering space of the mapping torus of $h$, equipped with the unique hyperbolic metric.

We then obtain a discrete and faithful representation

$$
\rho: \pi \rightarrow \Gamma<G=H \times H, \rho(\gamma)=\left(\rho_{+}(\gamma), \rho_{-}(\gamma)\right) .
$$

By the construction, the image of each element of $\pi$ is a semisimple element of $G$. Since the projections $\Gamma_{ \pm}$of $\Gamma$ to the factors $H_{ \pm}$of $H \times H$ are geometrically infinite, the representation

[^16]$\rho$ is not Anosov. It remains to prove that $\Gamma$ is undistorted in $G$, i.e. that the map $\rho$ is a qi embedding. This qi embedding condition can be reformulated as follows. Consider the closed convex hulls $C^{ \pm} \subset \mathbb{H}^{3}$ of the limit sets of the subgroups $\Gamma_{ \pm}<H$. The group $\pi$ acts properly discontinuously, isometrically and cocompactly on the boundaries of these convex hulls. Accordingly, we obtain quasiisometries
$$
\mathbb{H}^{2} \rightarrow \partial C^{ \pm}
$$
where the targets are equipped with intrinsic path-metrics. The quotient manifolds $C^{ \pm} / \Gamma_{ \pm}$ are isometric to the ends $E^{ \pm} \subset M^{ \pm}$. Since $C^{ \pm}$are isometrically embedded in $\mathbb{H}^{3}$, $\Gamma$ is qi embedded in $G$ if and only if the map
$$
f: \mathbb{H}^{2} \rightarrow \mathbb{H}^{3} \times \mathbb{H}^{3}
$$
given by the composition of the isometries $f_{ \pm}: \mathbb{H}^{2} \rightarrow \partial C^{ \pm}$with the inclusion maps $\partial C^{ \pm} \rightarrow$ $C^{ \pm} \rightarrow \mathbb{H}^{3}$, is a qi embedding. Since the ends $E^{ \pm}$are bilipschitz homeomorphic to the ends $E_{0}^{ \pm}$of the manifold $M_{0}, f$ is a qi embedding if and only if the following holds:

For some (every) $\Gamma_{0}$-invariant embedded simply-connected hypersurface $\Sigma \subset \mathbb{H}^{3}$ separating $\mathbb{H}^{3}$ into components $\Sigma^{ \pm}$(equipped with the induced path-metrics), the inclusion maps $\Sigma \rightarrow \Sigma^{ \pm}$combine to a qi embedding

$$
\Sigma \rightarrow \Sigma^{-} \times \Sigma^{+}
$$

Since $\mathbb{H}^{3}$ has a $\Gamma$-invariant structure of a metric bundle $\mathfrak{X}=(\pi: X \rightarrow T=\mathbb{R})$ with fibers uniformly qi to $\mathbb{H}^{2}$, we just need to prove that for some (every) vertex $v \in T$ and the ideal boundary points $\xi_{ \pm}$of $T=\mathbb{R}$, the inclusion maps $X_{v} \rightarrow X_{T_{ \pm}}=X_{\nu \xi_{ \pm}}$combine to a qi embedding

$$
\Phi: X_{v} \rightarrow X_{T_{+}} \times X_{T_{-}}
$$

where $T_{ \pm}=v \xi_{ \pm}$, a half-line. We will prove that $\Phi$ is indeed a qi embedding (and even more) below, Proposition 8.68.

Suppose $\mathfrak{X}=(\pi: X \rightarrow T)$ is a tree of hyperbolic metric spaces with hyperbolic total space $X$ and let $v \in V(T)$ be a vertex of finite degree $n \geq 2$, with edges $e_{1}, \ldots, e_{n}$ incident to $v$. For each $i=1, \ldots, n$, let $T_{i}$ denote the subtree in $T$ which is the union of subintervals of the form $\llbracket v, w \rrbracket$, containing the edge $e_{i}$. We then obtain the subtrees of spaces $\mathfrak{X}_{T_{i}}=\left(\pi: X_{T_{i}} \rightarrow T_{i}\right)$ in $\mathfrak{X}$. For each $i$, we let $f_{i}: X_{v} \rightarrow X_{T_{i}}$ denote the inclusion map. We equip the product $Q=\prod_{1 \leq i \leq n} X_{T_{i}}$ with the $\ell_{1}$-metric

$$
d_{Q}(p, q)=\sum_{i=1}^{n} d_{X_{T_{i}}}\left(p_{i}, q_{i}\right), \quad p=\left(p_{1}, \ldots, p_{n}\right), q=\left(q_{1}, \ldots, q_{n}\right) .
$$

(One can also use the $\ell_{2}$-metric, the product metric: The two metrics are qi to each other.)
In what follows, we take $K=K_{*}, D=D_{5.2}, E=E_{5.2}$, depending on the parameters of the tree of spaces $\mathfrak{X}$.

The next proposition is a generalization of a result from [KS20], where it was proven in the case when $\mathfrak{X}$ is a metric bundle:

Proposition 8.68. Under the above assumptions, the diagonal map

$$
\Phi: X_{v} \rightarrow Q=\prod_{1 \leq i \leq n} X_{T_{i}}, \quad x \mapsto\left(f_{i}(x)\right)
$$

is a qi embedding.

Proof. We note that the inclusion maps $X_{v} \rightarrow X_{T_{i}}$ are all 1-Lipschitz. Hence, the diagonal map $\Phi$ is $n$-Lipschitz. The proof of the proposition is divided in two cases.

Case 1: Suppose that $n=2$. Consider a pair of points $x, y \in X_{v}$ and let $\mathfrak{L}=\mathscr{L}(\alpha)=$ $\{\pi: L \rightarrow \pi(L)\}$ be a $(K, D, E)$-ladder centered at $v$, with $\alpha=[x y]_{X_{v}}=L_{v}$. For $i=1,2$, we have the $(K, D, E)$-ladders $\mathfrak{L}^{i}=\left\{L^{i} \rightarrow \pi(L) \cap T_{i}\right\}$ in $\mathfrak{X}_{T_{i}}$, obtained by pull-back of the ladder $\mathfrak{L}$ to the subtree of spaces $\mathfrak{X}_{T_{i}}$.

Let $c=c_{L}(x, y)$ be a combing path in $L$ connecting $x$ to $y$. We let $\hat{c}_{1}, \hat{c}_{2}$ be the paths in $L_{1}, L_{2}$ respectively, obtained from $c$ via the cut-and-replace procedure with respect to the inclusions $L_{1} \rightarrow L, L_{2} \rightarrow L$ (see Definition 8.12). Note that, since $L^{i}$ is a ladder in $X_{T_{i}}$, it is qi embedded in $X_{T_{i}}$. Moreover, according to Theorem 8.19, both $\hat{c}_{1}, \hat{c}_{2}$ are (uniform) $\kappa$-quasigeodesics in $X_{T_{i}}$. (Actually, this fact is established in Part I of the proof of Theorem 8.19.)

We will now estimate the length of $\alpha$ from above in terms of the distance between $\Phi(x), \Phi(y)$ in $Q$. We claim that the segment $\alpha$ is contained in the union $\hat{c}_{1} \cup \hat{c}_{2}$. Indeed, by the definition of combing paths $c=c_{L}$ in $L$, there exists a finite monotonic sequence $x_{0}=x, x_{1}, \ldots, x_{m}=y$ in $\alpha$ such that $c$ is the concatenation of paths $c\left(x_{i}, x_{i+1}\right)$ between points $x_{i}, x_{i+1}$, such that (after switching the roles of $L_{1}, L_{2}$ if necessary), $c\left(x_{i}, x_{i+1}\right)$ is contained in $L_{1}$ for odd $i$ and is contained in $L_{2}$ for even $i$. Now, it follows from the definition of the cut-and-replace procedure that $\left[x_{i} x_{i+1}\right]_{X_{v}} \subset \alpha$ is contained in $\hat{c}_{1}$ for each odd $i$ and is contained in $\hat{c}_{2}$ for even $i$.

Thus,

$$
\begin{array}{r}
d_{X_{v}}(x, y)=\text { length }(\alpha) \leq \text { length }\left(\hat{c}_{1}\right)+\text { length }\left(\hat{c}_{2}\right) \leq \\
(\kappa+1)\left(d_{X_{T_{1}}}(x, y)+d_{X_{T_{2}}}(x, y)\right)=2(\kappa+1) d(\Phi(x), \Phi(y))
\end{array}
$$

It follows that $\Phi$ is a qi embedding.
Case 2: Suppose that $n \geq 3$. Consider two points $x, y \in X_{v}$. Observe that for $p=$ $(x, x), q=(y, y) \in X_{T_{1}} \times X_{T_{2}}$, we have

$$
d_{Q}((\underbrace{x, \ldots, x}_{n \text { times }}),(\underbrace{y, \ldots, y}_{n \text { times }})) \geq d_{X_{T_{1}} \times X_{T_{2}}}(p, q) .
$$

Therefore, Case 1 implies that the diagonal embedding $\Phi: X_{v} \rightarrow Q$ is a qi embedding.
This concludes the proof of the theorem as well.
Question 8.69. In the example given in this theorem, is the subgroup $\Gamma<G$ a coarse Lipschitz retract of $G$ ?

Note that Anosov subgroups of semisimple Lie groups are coarse Lipschitz retracts, see [KL18b].
8.11.2. CT-maps for hyperbolic graphs of groups. In this section, $\mathcal{G}^{\prime}$ is a finite graph of hyperbolic groups satisfying Axiom $\mathbf{H}$, with the underlying connected graph $\Gamma^{\prime}$ and the Bass-Serre tree $T^{\prime}$. We will also assume that the group $G^{\prime}=\pi_{1}\left(\mathcal{G}^{\prime}\right)$ is hyperbolic.

We first prove the existence of CT-maps for some classes of hyperbolic subgroups $G<G^{\prime}$.

Proposition 8.70. Suppose that $\Gamma \subset \Gamma^{\prime}$ is a connected subgraph and $\mathcal{G} \subset \mathcal{G}^{\prime}$ is the subgraph of groups obtained by restricting $\mathcal{G}^{\prime}$ to $\Gamma$ (see Section 2.1), with $G=\pi_{1}(\mathcal{G})$. Then the subgroup $G<G^{\prime}$ admits a CT-map $\partial_{\infty} G \rightarrow \partial_{\infty} G^{\prime}$.

Proof. Let $T, T^{\prime}$ denote the Bass-Serre trees of $\mathcal{G}, \mathcal{G}^{\prime}$. The embedding of graphs of groups $\mathcal{G} \hookrightarrow \mathcal{G}^{\prime}$ induces a $G$-equivariant embedding $T \hookrightarrow T^{\prime}$. Since the subgraph of groups $\mathcal{G} \subset \mathcal{G}^{\prime}$ is obtained by the restriction, for each vertex $v$ and edge $e$ of the subtree $T^{\prime}$, the stabilizer of $v$ (resp. $e$ ) in $G$ equals its stabilizer in $G^{\prime}$. Thus, the tree of spaces $\mathfrak{X}=(\pi$ : $X \rightarrow T)$ corresponding to the graph of groups $\mathcal{G}$ is obtained as the pull-back of the tree of spaces $\mathfrak{X}^{\prime}=\left(\pi: X^{\prime} \rightarrow T^{\prime}\right), X=X_{T}^{\prime}$. Since the groups $G, G^{\prime}$ are naturally quasiisometric to the spaces $X, X^{\prime}$ (via respective orbit maps) the existence of a CT-extension for the embedding $G^{\prime} \rightarrow G$ is equivalent to that of the embedding $X^{\prime} \rightarrow X$. Since the existence of a CT-map for the inclusion $X^{\prime} \hookrightarrow X$ is the content of Theorem 8.11 , the proposition follows.

The next theorem shows that one does not need to restrict to subgraphs of $\mathcal{G}^{\prime}$ to obtain subgroups with CT-maps:

Theorem 8.71. Assume that $G<G^{\prime}=\pi_{1}\left(\mathcal{G}^{\prime}\right)$ is a subgroup preserving a subtree $T \subset T^{\prime}$ such that the quotient graph $T / G$ is finite and that the vertex and edge stabilizers of this action on $T$ are quasiconvex in the respective subgroups of $G^{\prime}: G_{v}<G_{v}^{\prime}$ and $G_{e}<G_{e}^{\prime}$ are quasiconvex for all $v \in V(T), e \in E(T)$. Then the subgroup $G$ is hyperbolic and the inclusion map $G \rightarrow G^{\prime}$ admits a CT-map.

Proof. We will use Proposition 2.29: As in the proof of the proposition we observe that the $G$-action on $T$ defines a graph-of-groups decomposition of $G: \pi_{1}(\mathcal{G})=G$, and the graph of groups $\mathcal{G}$ satisfies Axiom $\mathbf{H}$ (in view of the quasiconvexity assumptions in the theorem). We let $\mathfrak{X}=(\pi: X \rightarrow T)$ and $\mathfrak{X}^{\prime}=\left(\pi: X^{\prime} \rightarrow T^{\prime}\right)$ denote the trees of spaces corresponding to the graphs of groups $\mathcal{G}, \mathcal{G}^{\prime}$ respectively.

Since $G^{\prime}$ is hyperbolic, so is $X^{\prime}$ and, hence, $\mathfrak{X}^{\prime}$ satisfies the proper flaring condition. We have a $G$-equivariant relatively retractive morphism of trees of spaces $\mathfrak{X} \rightarrow \mathfrak{X}^{\prime}\left(h: X \rightarrow X^{\prime}\right.$, over the inclusion $T \rightarrow T^{\prime}$ ). The proper flaring condition for $\mathfrak{X}^{\prime}$ then implies the proper flaring condition for $\mathfrak{X}$, hence, $X$ and, thus, $G$, is also hyperbolic. We let $\mathfrak{Y})=\left(\pi: X_{T}^{\prime} \rightarrow T\right)$ denote the restriction of the tree of spaces $\mathfrak{X}^{\prime}$ to $T$. The quasiconvexity assumption for the subgroups $G_{v}<G_{v}^{\prime}, G_{e}<G_{e}^{\prime}, v \in V(T), e \in E(T)$, implies that for each $v \in V(T)$, and edge $e=[v, w] \in E(T)$, the $G_{v}$-orbit of $X_{e v}^{\prime}$ is locally finite in $X_{v}^{\prime}$, see Lemma 1.6. Thus, Proposition 2.29 implies that the map $h: X \rightarrow Y=X_{T}^{\prime}$ is a qi embedding. According to Theorem 8.11, the inclusion $Y \rightarrow X^{\prime}$ admits a CT-map $\partial_{Y, X^{\prime}}$. Composing it with the boundary map of the qi embedding $X \rightarrow Y$, we obtain a CT-map $\partial_{\infty} h$ for the map $h: X \rightarrow$ $X^{\prime}$. Since $G$ acts geometrically on $X$ and $G^{\prime}$ acts geometrically on $X^{\prime}$ (see Section 1.3 for the definition and Lemma 1.31), we conclude from the existence of $\partial_{Y, X^{\prime}}$ the existence of a CT-map for the subgroup $G<G^{\prime}$.

Example 8.72. Let $G^{\prime}=F \star_{\varphi}$ be a hyperbolic group which is the descending HNN extension of a finitely generated free group $F$ via an injective endomorphism $\varphi: F \rightarrow F$. Then $G=F \star_{\varphi^{n}}$ is a hyperbolic subgroup of $G^{\prime}$ and the embedding $G \rightarrow G^{\prime}$ admits a CT-map.

For a boundary vertex $v$ of a subtree $T \subset T^{\prime}$, we let $T^{\prime}(v) \subset T^{\prime}$ denote the maximal subtree of $T^{\prime}$ containing $v$ and disjoint from the rest of the vertices of $T$. Thus, if $g$ is an automorphism of $T$ fixing $v$ and preserving $T$, it preserves the subtree $T^{\prime}(v)$ as well.

Theorem 8.73. Assume that $G<G^{\prime}$ are as in Theorem 8.71 and that for each boundary vertex $v$ of $T$ in $T^{\prime}$, the stabilizer $G_{v}<G$ acts $k$-acylindrically on the subtree $T^{\prime}(v) \subset T^{\prime}$. Then $G$ is a quasiconvex subgroup of $G^{\prime}$.

Proof. According to Remark 8.9(2), in order to prove the quasiconvexity of $G$ in $G^{\prime}$ it suffices to show that the CT-map $\partial_{G, G^{\prime}}$ is injective, i.e. that the CT-lamination $\Lambda\left(G, G^{\prime}\right)$ is empty. For the sake of contradiction, suppose that $\Lambda\left(G, G^{\prime}\right) \neq \emptyset$. As we observed in the proof of Theorem 8.71, the action of $G$ on the space $Y=X_{T}^{\prime}$ is quasiconvex. Since $\Lambda\left(G, G^{\prime}\right) \neq \emptyset$, follows that there exists a pair of distinct limit points $z_{ \pm}$of $G$ in $\partial_{\infty} Y$ with equal images under $\partial_{Y, X^{\prime}}$. By Proposition 8.47, there is a biinfinite vertical geodesic $\alpha \subset X_{v}^{\prime}$ (for some $v \in V(T)$ ) which is a quasigeodesic in $Y$, such that $z_{ \pm}=\alpha( \pm \infty)$.

Lemma 8.74. Suppose that $\rho$ is a geodesic ray in a vertex-space $X_{v}^{\prime}, v \in T$, which is also a quasigeodesic ray in $Y$, such that $z=\rho(\infty)$ is a limit point of $G$ in $\partial_{\infty} Y$. Then $z$ is a (conical) limit point of the action of $G_{v}$ on $X_{v}^{\prime}$.

Proof. Since the $G$-action on $Y$ is quasiconvex, the limit point $z$ is a conical limit point (see Definition 1.135). Thus, there is a sequence $g_{i} \in G$ and a constant $r$ such that for $x=\rho(0), d\left(g_{i} x, \rho\right) \leq r$, and $\lim _{i \rightarrow \infty} g_{i}(x)=z$. At the same time, the $G$-orbit of $X_{v}^{\prime}$ in $Y$ is locally finite (since for $g \in G, g X_{v}^{\prime}=X_{g v}^{\prime}$ and each compact in $X$ intersects only finitely many vertex-spaces). Since $g_{i}(x) \in N_{r}\left(X_{v}^{\prime}\right)$, Proposition 1.134 implies that $g_{i}(x) \in N_{R}\left(G_{v} x\right)$ for some $R$ independent of $i$. Hence, for $h_{i} \in G_{v}$ such that $d\left(g_{i}(x), h_{i}(x)\right) \leq R$, we obtain $\lim _{i \rightarrow \infty} h_{i}(x)=z$ in $X_{v}^{\prime}$.

We now return to the proof of the theorem. By the lemma, the points $z_{ \pm}$are limit points of the $G_{v}$-action on $X_{v}^{\prime}$. Since $\partial_{Y, X^{\prime}}\left(z_{-}\right)=\partial_{Y, X^{\prime}}\left(z_{+}\right)$and $z_{ \pm} \in \partial_{\infty} X_{v}^{\prime} \subset \partial_{\infty} Y$ are limit points of the $G_{v}$-action on $X_{v}^{\prime}$, Theorem $8.60(1)$ implies that there is a point $\xi \in \partial_{\infty} T^{\prime} \backslash \partial_{\infty} T$ such that $\left\{z_{-}, z_{+}\right\} \in \Lambda^{\xi}\left(X_{v}^{\prime}, X^{\prime}\right)$. By Proposition 8.54(2), for each vertex $w \in V(v \xi), F l_{w}\left(\left\{z_{ \pm}\right\}\right) \neq \emptyset$. Thus, according to Lemma 3.35, for each $x \in X_{v}$ and vertex $w \in v \xi$, the pair of subsets $G_{v} x, X_{w}^{\prime}$ is not cobounded in $X_{v w}$. Lemma 2.35 then implies that the $G_{v}$-stabilizer of the interval $J_{w}=\llbracket v, w \rrbracket$ is infinite for each $w \in V(v \xi)$. Since $\xi \in \partial_{\infty} T^{\prime} \backslash \partial_{\infty} T$, the intersection of the ray $v \xi$ with the subtree $T$ is a finite interval $\llbracket v, v^{\prime} \rrbracket$. The vertex $v^{\prime}$ is a boundary vertex of $T$ in $T^{\prime}$. Let $G_{J_{w}}$ denote the $G$-stabilizer of the interval $J$. Consider a vertex $w \in v \xi$ such that $v^{\prime} \in V(\llbracket v, w \rrbracket)$ and, moreover, $d_{T}\left(v^{\prime}, w\right)>k$. Then the infinite subgroup $G_{J} \cap G_{v}$ fixes the interval $\llbracket v^{\prime}, w \rrbracket \subset T^{\prime}\left(v^{\prime}\right)$ of length $>k$, contradicting the hypothesis that the group $G_{v^{\prime}}$ acts $k$-acylindrically on the subtree $T^{\prime}\left(v^{\prime}\right)$.

Remark 8.75. Assume that $G<G^{\prime}$ are as in Theorem 8.71.

1. The subgroup $G$ is at most exponentially distorted in $G^{\prime}$ since $Y$ is at most exponentially distorted in $X^{\prime}$ (Corollary 2.19) and the orbit map $o_{y}: G \rightarrow G y \subset Y$ is a qi embedding.
2. In the setting of Theorem 8.71, we can drop the assumption of hyperbolicity for $G^{\prime}$, but assume that for each boundary vertex $v \in T$ and the boundary edge $e=[v, w]$ the stabilizer $G_{e}$ is finite. Then $G$ is a coarse Lipschitz retract of $G^{\prime}$, since for each boundary edge $e$ the projection of $G_{v}$ to $G_{e}^{\prime}$ is uniformly bounded, cf. Theorem 2.21 and Proposition 2.29.
3. In [BR13] Baker and Riley construct examples of finitely generated free subgroups $G$ in certain hyperbolic groups $G^{\prime}$ such that the CT-maps for the inclusions $G \rightarrow G^{\prime}$ do not exist. Their groups $G^{\prime}$ free-by-cyclic, hence, are isomorphic to fundamental groups of graphs of groups $\mathcal{G}^{\prime}$ satisfying Axiom $\mathbf{H}$. However, in their examples, the intersections of $G$ with vertex/edge subgroups of $\mathcal{G}^{\prime}$ are not finitely generated.

The next result is a direct group-theoretic application of Proposition 8.47 regarding the nature of CT-laminations for subgraphs of groups:

Corollary 8.76. Suppose that $G<G^{\prime}$ are as in Proposition 8.70 and $\xi^{ \pm} \in \partial_{\infty} G$ are distinct points which have the same image in $\partial_{\infty} G^{\prime}$ under the CT-map $\partial_{\infty} G \rightarrow \partial_{\infty} G^{\prime}$. Then there exists a vertex $v \in T$ and a pair of points $\xi_{v}^{ \pm} \in \partial_{\infty} G_{v}$ such that:

1. $\partial_{G_{v}, G}\left(\xi_{v}^{ \pm}\right)=\xi^{ \pm}$.
2. Geodesics in $G_{v}$ connecting $\xi_{v}^{ \pm}$are uniform quasigeodesics in $G$.

Here is another application, this time of Theorem 8.50. Consider a hyperbolic group $H$, an automorphism $f: H \rightarrow H$ and the semidirect product $G=H \rtimes_{f} \mathbb{Z}$. The next result describes when a geodesic in $H$ is a leaf of the CT-lamination $\Lambda(H, G)$. For the formulation of the result we will use the notion of pseudo-orbits of the automorphism $f$, Definition 2.66.

Corollary 8.77. A geodesic $\alpha$ in the Cayley graph of $H$ is a leaf of $\Lambda(H, G)$ if and only if the following holds for some numbers $K \geq 1$ and $C \geq 0$ :

There exist $K$-pseudo-orbits $\left(y_{i}^{ \pm}\right)$, of $h_{ \pm n}=\alpha( \pm n) \in H$ under the automorphism $f$ which approach each other within distance C. More precisely, there exist $i=i(n)$ such that

$$
d_{H}\left(y_{i}^{+}, y_{i}^{-}\right) \leq C .
$$

Proof. We let $\mathfrak{X}=(\pi: X \rightarrow \mathfrak{I}=\mathbb{R})$ denote the tree of spaces corresponding to the graph-of-groups structure on $G$ given by the HNN-extension of $H$ via the automorphism $f$.

Suppose that $\mathfrak{A}^{n}=\left(\pi: A^{n} \rightarrow \llbracket 0, w_{n} \rrbracket\right), w_{n}=i=i(n)$, is a $(K, C)$-narrow carpet in $G$ bounded by $\left[h_{-n} h_{n}\right]_{X_{0}}$ and $\gamma_{n}^{ \pm}$denote the $K$-qi sections corresponding to the top/bottom of the carpet $\mathfrak{A}^{n}$. By the definition of a $(K, C)$-narrow carpet,

$$
d_{t^{i} H}\left(\gamma_{n}^{-}(i), \gamma_{n}^{+}(i)\right) \leq C .
$$

As it was explained in Section 2.7, for each $n$, the sequences $y_{j}^{ \pm}=\gamma_{n}^{ \pm}(j)$ are precisely the partial pseudo-orbits of $f$ in $H$ through the points $h_{ \pm n}$. Thus, the claim is a direct consequence of Theorem 8.50.

Remark 8.78. One can show that $\alpha$ as above is a leaf of $\Lambda(H, G)$ if and only if there are sequences $h_{ \pm n}$ in $H$ converging to $\alpha( \pm \infty)$ (but not necessarily of the form $\alpha( \pm n)$ ), such that the $f$-orbits of $h_{ \pm n}$ approach each other within distance $C$, where $C$ is a uniform constant depending only on the group $H$, its generating set, and $f$.
8.11.3. Miscellaneous results. The next proposition is a partial converse to Proposition 8.64:

Proposition 8.79. Suppose $\mathcal{G}$ is a finite graph of hyperbolic groups satisfying Axiom $\mathbf{H}$ and $G=\pi_{1}(\mathcal{G})$ is hyperbolic. Suppose $X \rightarrow T$ is the tree of spaces associated to this graph of groups. If $v$ is a vertex of $T$ and $z \in \partial_{\infty} X_{v}$ is such that the subtree $T_{z}=\pi(F l(\{z\}))$ contains no geodesic rays, then $\partial_{X_{v}, X}(z)$ is a conical limit point of $X_{v}$ in $X$.

Proof. By the definition, $T_{z} \subset T$ is the subtree whose vertex set consists of those vertices $w \in V(T)$ for which $F l_{w}(z) \neq \emptyset$.

Lemma 8.80. The subtree $T_{z}$ is finite.
Proof. Since $T_{z}$ contains no rays, it suffices to prove that the tree $T_{z}$ is locally finite. Consider a vertex $w \in T_{z}$ and the collection of edges $e_{i}, i \in I$, in $T_{z}$ incident to $w$. Let $F l_{w}(\{z\})=\left\{z^{\prime}\right\}, z^{\prime} \in \partial_{\infty} X_{w}$. Then, according to the definition of the boundary flow in Section 3.3.4, for each edge $e_{i}$ we have $F l_{e_{i}}\left(\left\{z^{\prime}\right\}\right) \neq \emptyset$. It follows that $z^{\prime} \in \partial_{\infty}\left(G_{e_{i}}, G_{w}\right)$ for
each $i \in I$. Since $\mathcal{G}$ is a finite graph of groups, there are only finitely many $G_{w}$-conjugacy classes of edge-stabilizers $G_{e_{i}}<G_{w}$. At the same time,

$$
z^{\prime} \in \bigcap_{i \in I} \partial_{\infty}\left(G_{e_{i}}, G_{w}\right) \neq \emptyset,
$$

hence (since each subgroup $G_{e_{i}}$ is quasiconvex in $G_{w}$ ) each intersection $G_{e_{i}} \cap G_{e_{j}}$ is an infinite subgroup of $G_{w}$, see e.g. Lemma 2.6 in [GMRS98]. The main theorem in [GMRS98] states that quasiconvex subgroups of hyperbolic groups have finite width. Without defining width of subgroups here, we only note that, as a consequence of this finiteness theorem, if $H_{i}, i \in I$, is a collection of pairwise distinct quasiconvex subgroups of a hyperbolic group $H$ which belong to finitely many $H$-conjugacy classes and $\left|H_{i} \cap H_{j}\right|=\infty$ for all $i, j \in I$, then $I$ is finite. Applying this result in our setting, with the ambient hyperbolic group $H$ equal $G_{w}$ and quasiconvex subgroups $H_{i}$ equal to the edge-subgroups $G_{e_{i}}$, we conclude that the set $I$ is finite. Thus, $T_{z}$ is a locally finite tree and, hence, is finite.

We can now prove the proposition. In the proof it will be convenient to assume that each edge-space $X_{e}$ of $\mathfrak{X}$ is discrete, cf. introduction to Section 8.7. Let $\beta$ be a ray in $X$ asymptotic to the point $\partial_{X_{v}, X}(z)$. Suppose for a moment that the intersection $\beta \cap X_{T_{z}}$ is bounded. Then there exists a boundary edge $e=\left[v^{\prime}, w\right]$ of $T_{z}, w \notin V\left(T_{z}\right), v^{\prime} \in V\left(T_{z}\right)$, such that an unbounded subray $\beta^{\prime}$ of $\beta$ projects to the subtree $T_{w, z} \subset T$ which is the maximal subtree of $T$ containing $w$ and disjoint from $T_{z}$. (Here are are using the discreteness assumption on the edge-spaces of $\mathfrak{x}$.) Let $K$ be as in Proposition 8.54 and let $\alpha \subset X_{v}$ be a geodesic ray asymptotic to $z$.

Since $w \notin T_{z}=\pi(F l(\{z\}))$, the intersection $F l_{K}(\alpha) \cap X_{w}$ is bounded, cf. Lemma 3.35. Recall that the flow-space $F l_{K}(\alpha)$ is quasiconvex in $X$. Hence, we will identify $\partial_{\infty} F l_{K}(\alpha)$ with a subset of $\partial_{\infty} X$. We claim that

$$
\partial_{\alpha, F l_{K}(\alpha)}(z) \neq \beta(\infty) \in \partial_{\infty} F l_{K}(\alpha)
$$

Indeed, the assumption that $\pi\left(\beta^{\prime}\right) \subset T_{w, z}$ implies that each geodesic in $F l_{K}(\alpha)$ connecting points of $\alpha$ to that of $\beta^{\prime}$ has to pass through $F l_{K}(\alpha) \cap X_{w}$, i.e. within distance $D$ from $p=\alpha(0)$, where $D=\operatorname{Hd}\left(\{p\}, F l_{K}(\alpha) \cap X_{w}\right)$. But this means that the sequences $(\alpha(n)),(\beta(n))$ cannot define the same ideal boundary point of $\partial_{\infty} F l_{K}(\alpha)$. Quasiconvexity of $F l_{K}(\alpha) \subset X$ implies that $\partial_{X_{v}, X}(z) \neq \beta(\infty)$, which is a contradiction. Thus, $\beta$ contains an unbounded sequence of points $\left(x_{n}\right)$ contained in $Y:=F l_{K}(\alpha) \cap X_{T_{z}}$. Since (by the lemma) the subtree $T_{z}$ is finite, the subset $Y$ is Hausdorff-close to the ray $\alpha \subset X_{v}$. In other words, the point $\partial_{X_{v}, X}(z)=\beta(\infty)$ is a conical limit point of $X_{v}$.

We conclude the chapter with a proposition that deals with the case of nonhyperbolic graphs of hyperbolic groups and relates this lack of hyperbolicity to various notions discussed earlier, such as boundary flow-spaces and unbounded sequences of carpets:

Proposition 8.81. Suppose $\mathcal{G}$ is a finite graph of hyperbolic groups satisfying Axiom $\mathbf{H}$; let $\mathfrak{X}=(\pi: X \rightarrow T)$ denote the corresponding tree of metric spaces. If $G=\pi_{1}(\mathcal{G})$ is not hyperbolic, then there is a vertex $v \in V(T)$ such that $\pi\left(F l\left(\partial_{\infty} X_{v}\right)\right)$ contains a geodesic ray.

Proof. Let $G$ be the fundamental group of $\mathcal{G}$. By Corollary 2.49(2) there is a constant $D>0$, a sequence of intervals $I_{n}=\llbracket-t_{n}, t_{n} \rrbracket \subset T$ of length at least $n$ and a sequence ( $\Pi^{n}$ ) of pairs of $\kappa$-qi sections $\left(\gamma_{0}^{n}, \gamma_{1}^{n}\right)$ over $I_{n}(n \in \mathbb{N})$, such that $\Pi_{\max }^{n} \leq D$, but $\Pi_{0}^{n} \rightarrow \infty$. Since the $G$-action is cofinite on $T$ and cocompact on $X$, and the map $\pi: X \rightarrow T$ is $G$ equivariant, after extraction, we may assume that for each $n$ the midpoint of $I_{n}$ is a fixed vertex $v \in V(T)$ and the midpoint of $\left[\gamma_{0}^{n}(0) \gamma_{1}^{n}(0)\right]_{X_{v}}$ is within unit distance from a fixed
point $x \in X_{v}$. After passing to a further subsequence, we may assume that the sequence of segments $\left[\gamma_{0}^{n}(0) \gamma_{1}^{n}(0)\right]_{X_{v}}$ converges to a complete geodesic in $X_{v}$. We note that for each $n$ the vertical geodesic segments $\left[\gamma_{0}^{n}(t) \gamma_{1}^{n}(t)\right]_{X_{t}}, t \in V\left(I_{n}\right)$, form a $K$-metric bundle over $I_{n}$ (with $K=\kappa^{\prime}$, see Lemma 3.17) and hence there is a $K$-qi section $\gamma^{n}$ over $I_{n}$ passing through $B(x, 2)$ and contained in this metric bundle. Hence, after passing to a further subsequence, we may assume that the sequence of sections $\left(\gamma^{n}\right)$ converges to a complete quasigeodesic $\gamma$ in $X$ and the sequence $I_{n}$ converges of complete geodesic $I$ in $T$ such that $\gamma$ is a qi section over $I$, cf. the proof of Lemma 8.57(2). Lastly, Lemma 3.35(3) implies that $I \subset \pi\left(F l\left(\partial_{\infty} X_{v}\right)\right)$.

## CHAPTER 9

## Cannon-Thurston maps for relatively hyperbolic spaces

The goal of this chapter is to generalize the results on Chapter 8 (primarily, the existence of CT-maps and some basic facts about CT-laminations) in the context of relatively hyperbolic spaces. Such a generalization was achieved in [MP11] for the inclusion maps of vertex-spaces.

### 9.1. Relative hyperbolicity

9.1.1. Relative hyperbolicity in the sense of Gromov. We refer the reader to [Far98, Bow12] for the background on the theory of relatively hyperbolic spaces. Briefly, a relatively hyperbolic space is a pair $(Y, \mathcal{H})$ consisting of a geodesic metric space $(Y, d)$ together with a collection $\mathcal{H}=\left\{H_{i}: i \in I\right\}$ of peripheral subspaces, which are nonempty subsets of $Y$ satisfying certain conditions discussed below and, in an alternative form, in Section 9.2.1. While this is not always required for relatively hyperbolic spaces, we will assume that each $H_{i} \in \mathcal{H}$ is rectifiably connected and the inclusion maps $\left(H_{i}, d_{H_{i}}\right) \rightarrow\left(Y, d_{Y}\right)$ are uniformly proper, where $d_{H_{i}}$ are the intrinsic path-metrics on $H_{i}$ 's. Given such a pair $(Y, \mathcal{H})$, one defines two new metric spaces:

1. The extended hyperbolic space $\left(Y^{h}, d^{h}\right)=\left(Y^{h}, d_{Y^{h}}\right)=\mathcal{G}(Y, \mathcal{H})$ (or the horoballification of $(Y, \mathcal{H})$ ), which is a path-metric space obtained by attaching along each $H_{i}$ its hyperbolic cone $H_{i}^{h}$ defined in Section 1.11; the latter are (intrinsically) uniformly hyperbolic horoballs, with $H_{i}$ the boundary horosphere in $H_{i}^{h}$. Recall that each $H_{i}^{h}$ has unique ideal boundary point, called the foot-point (or the ideal center) of $H_{i}^{h}, \xi\left(H_{i}^{h}\right)$.
2. The electric space $\left(Y^{\ell}, d^{\ell}\right)=\mathcal{E}(Y, \mathcal{H})$ (the electrification of $(Y, \mathcal{H})$ ), obtained by coning off each $H_{i}$, i.e. attaching to $Y$ along each $H_{i}$ the cone $H_{i}^{\ell}=C\left(a_{i}, H_{i}\right)$ with the apex $a_{i}=a\left(H_{i}^{\ell}\right)$ within distance $1 / 2$ from each point in $H_{i}$. We refer the reader to Section 1.7 for the precise definition of the metric spaces $C\left(a_{i}, H_{i}\right)$. Here we recall only that each point $x \in H_{i}$ is connected to $a_{i}$ by a canonical geodesic segment of length $1 / 2$, called a radial line-segment. The set of apexes of these cones is called the cone-locus of $Y^{\ell}$ and denoted $a\left(Y^{\ell}\right)$.

We will use the notation $\stackrel{\circ}{H}_{i}^{h}$ (the open peripheral horoball) and $\check{H}_{i}^{\ell}$ (the open peripheral cone) for the complements

$$
H_{i}^{h} \backslash H_{i}, \quad H_{i}^{\ell} \backslash H_{i}
$$

respectively.
Definition 9.1 (Relative hyperbolicity in the sense of Gromov). A pair $(Y, \mathcal{H})$ is called relatively hyperbolic in the sense of Gromov (GRH) if the metric space ( $Y^{h}, d^{h}$ ) is hyperbolic.

If $(Y, \mathcal{H})$ is GRH, then the electric space $\left(Y^{\ell}, d^{\ell}\right)$ is hyperbolic. This is a standard fact, usually attributed to Farb, [Far98]: Although the proofs given in his paper are only in the
setting of manifolds of negative curvature, they go through in greater generality. We will give a proof in Section 9.2 with the side-benefit of relating quasigeodesics in $\left(Y^{h}, d^{h}\right)$ to those in $\left(Y^{\ell}, d^{\ell}\right)$.
9.1.2. Extrinsic geometry of the peripheral horoballs. Throughout this section we will assume that $(Y, \mathcal{H})$ is GRH with the hyperbolicity constant $\delta$. Our goal is to discuss the extrinsic geometry of the peripheral horoballs $H_{i}^{h}$. Among other things, we will prove that they are uniformly quasiconvex and uniformly pairwise cobounded.

Lemma 9.2. 1. The subsets $H_{i}^{h}$ are $\lambda_{9.2}(\delta)$-quasiconvex and $L_{9.2}(\delta)$-qi embedded in $Y$.
2. $Y$ is uniformly properly embedded in $Y^{h}$ with the distortion function depending only on $\delta$.

Proof. 1. We observe that, by the definition of the metric on $H_{i}^{h}$, for each point $x=$ $(z, t) \in H_{i}^{h}$ the distance from $x$ to $H_{i}$ equals $\log (t)$. It follows that for any two points $x_{1}=\left(z, t_{1}\right), x_{2}=\left(z, t_{2}\right) \in H_{i}^{h}$,

$$
d_{Y^{n}}\left(x_{1}, x_{2}\right)=\left|\log \left(t_{1} / t_{2}\right)\right|
$$

and the vertical segment in $H_{i}^{h}$ between $x_{1}, x_{2}$ is isometrically embedded in $Y^{h}$. In particular, the vertical rays in $H_{i}^{h}$ are isometrically embedded in $Y^{h}$. Since any two such rays $\rho_{1}(t), \rho_{2}(t)$ converge as $t \rightarrow \infty$, it follows that the horoballs $H_{i}^{h}$ are uniformly quasiconvex in $Y^{h}$. The fact that the peripheral subspaces $H_{i}^{h}$ are uniformly properly embedded in $Y$ implies that the horoballs $H_{i}^{h}$ are uniformly properly embedded in $Y^{h}$. Combined with the uniform quasiconvexity, we obtain that these horoballs are uniformly qi embedded in $Y^{h}$.
2. Lastly, uniform properness of the inclusion maps $H_{i} \rightarrow H_{i}^{h}$ (see Proposition 1.71) implies that $Y$ is uniformly properly embedded in $Y^{h}$ as well.

Recall that a closed subset $C$ of a geodesic metric space $X$ is called strictly convex if for any two points $x, y \in C$, every geodesic $x y \subset X$ is contained in the interior of $C$, except maybe for its end-points. For instance, closed balls and horoballs in the classical hyperbolic space are strictly convex, while a closed hyperbolic half-space is not. The next lemma establishes a form of coarse strict convexity of peripheral horoballs in the context of GRH spaces.

Lemma 9.3. There exist $L=L_{9.3}(K, r, \delta)$ and $R=R_{9.3}(K, r, \delta)$ satisfying the following properties. Suppose that $\beta:[0, T] \rightarrow Y^{h}$ is a continuous $K$-quasigeodesic in $Y^{h}$ connecting points $z=\beta(0), y=\beta(T)$.

1. Suppose that the image of $\beta$ is entirely contained in $N_{r}(H)$ for some $H \in \mathcal{H}$. Then $d(y, z) \leq R=R_{9.3}(K, r, \delta)$.
2. Suppose that the points $z=\beta(0), y=\beta(T)$ both belong to $N_{r}\left(H^{h}\right) \backslash \stackrel{\circ}{H}^{h}$. Then either $T \leq 2 L$ or there exist $a \in[0, L]$ and $b \in[T-L, T]$ such that $z^{\prime}=\beta(a) \in H, y^{\prime}=\beta(b) \in H$ and the subpath $\beta\left(z^{\prime}, y^{\prime}\right)$ in $\beta(z, y)$ is entirely contained in $\stackrel{\circ}{H}^{h}$, except for the end-points $z^{\prime}, y^{\prime}$.

Proof. 1. Let $\bar{y}, \bar{z} \in H^{h}$ be the images of $y, z$, respectively, under the projection $P_{Y^{h}, H^{h}}$. Thus, $d(y, \bar{y}) \leq r, d(z, \bar{z}) \leq r$. Let $c=c(\bar{z}, \bar{y})$ denote the combing path in $H^{h}$ connecting $\bar{z}$ to $\bar{y}$, as defined in the proof of Proposition 1.68. By the version of stability of quasigeodesics in hyperbolic spaces (Lemma 1.54), the Hausdorff distance between the images of $\beta$ and $c$ is at most $D_{1.54}(\delta, \max (k, K), r)$, where $k$ is the bound on qi constant of $c$ given in Remark 1.69.

We will consider the case when $\bar{x}, \bar{y}$ are both in $H$ and leave the other cases to the reader as the proofs are similar. According to the description of the combing paths in
$H^{h}$, for each constant $D \geq 0$ if the path $c$ is contained in the $D$-neighborhood of $H$, then $A=d_{H}(\bar{z}, \bar{y}) \leq e^{D}$.

In our case, $c$ is contained in the $D=\left(D_{1.54}(\delta, \max (k, K), r)+r\right)$-neighborhood of $H$ and, hence, we conclude that $d_{H}(\bar{z}, \bar{y}) \leq e^{D}$. It follows that

$$
d(y, z) \leq R_{9.3}(K, r, \delta):=e^{D}+2 r
$$

2. We follow the arguments of Part 1, define points $\bar{y}, \bar{z}$ and the path $c$ connecting them, setting now $D:=D_{1.54}(\delta, \max (k, K), r)$, an upper bound on the Hausdorff distance between $\beta$ and $c$. If $d_{H}(\bar{z}, \bar{y})>e^{D}$, then there are points $\bar{y}^{\prime}, \bar{z}^{\prime}$ within distance $D$ from $\bar{y}, \bar{z}$ respectively, such that the subpath $c(\bar{z}, \bar{y})$ is disjoint from the $D$-neighborhood of $H$, apart from the end-points. Thus, there are points $y^{\prime \prime}, z^{\prime \prime}$ in the image of $\beta$ which are within distance $D$ from, respectively, $\bar{y}^{\prime}, \bar{z}^{\prime}$, such that the subpath $\beta\left(z^{\prime \prime}, y^{\prime \prime}\right)$ is entirely contained in $H^{h}$, except, possibly, the end-points. We then take the points $y^{\prime}, z^{\prime}$ on the subpaths $\beta\left(y, y^{\prime \prime}\right), \beta\left(z, z^{\prime \prime}\right)$ where these paths cross into $H^{h}$ and such that $\beta\left(z^{\prime}, y^{\prime}\right)$ is entirely contained in $\stackrel{\circ}{H}^{h}$, except for the end-points $x^{\prime}, y^{\prime}$. Lemma follows.

Corollary 9.4. Suppose that $y, z \in N_{r}\left(H^{h}\right)$ and the geodesic $[y z]_{Y^{h}}$ is disjoint from $\dot{H}^{h}$. Then $d(y, z) \leq 2 L_{9.3}(1, r, \delta)$.

Corollary 9.5. Suppose that $H_{i}, H_{j}$ are distinct elements of $\mathcal{H}, \beta:[0, T] \rightarrow Y$ is a K-quasigeodesic, $\left[s_{i}, t_{i}\right],\left[s_{j}, t_{j}\right]$ are subintervals of length $>2 L_{9.3}(K, r, \delta)$ in $[0, T]$ such that $\beta\left(s_{i}\right) \in H_{i}, \beta\left(t_{i}\right) \in H_{i}, \beta\left(s_{j}\right) \in H_{j}, \beta\left(t_{j}\right) \in H_{j}$. Then $\left[s_{i}, t_{i}\right] \cap\left[s_{j}, t_{j}\right]=\emptyset$.

Figure 40

Lemma 9.6. Consider three points, $x \in H^{h}, z \in H$ and $y \in Y^{h}$, and $K$-quasigeodesics $\alpha=\alpha(z, x), \beta=\beta(y, z)$ in $Y^{h}$ connecting $z$ to $x$ and $y$ to $z$ respectively, such that $\beta$ is disjoint from $\stackrel{\circ}{H}^{h}$ and $\alpha$ is contained in $H^{h}$. (See Figure 40.) Then the concatenation $\beta \star \alpha$ is an $L_{9.6}(K, \delta)$-quasigeodesic in $Y^{h}$.

Proof. We set $D:=D_{1.53}(\delta, K), R:=R_{9.3}(1, D, \delta)+1$. Note that $D>2 \delta$, see Lemma 1.53.

In view of stability of quasigeodesics, it suffices to get an upper bound on the qi constant of the concatenation $\beta^{*} \star \alpha^{*}$, where $\alpha^{*}=[z x]_{Y^{h}}, \beta^{*}=[y z]_{Y^{h}}$ (geodesics which are $D$-Hausdorff close to $\alpha, \beta$, respectively, where $D=D_{1.53}(\delta, K)$ ). By the assumption of the corollary, $\beta^{*}$ is contained in $N_{D}\left(Y^{h} \backslash H^{h}\right)$. There are two cases to consider:
a. $d_{Y^{h}}(y, z)<R$ or $d_{Y^{h}}(x, z)<R$. Then the claim follows immediately: A concatenation of a uniform quasigeodesic with a uniformly bounded quasigeodesic is again a uniform quasigeodesic.
b. $R \leq \min (d(x, z), d(y, z))$. Then, by Lemma 9.3(1), there exists a point $z^{\prime} \in \beta^{*}$ at the distance $R^{\prime} \leq R$ from $z$ such that $z^{\prime} \notin N_{D}\left(H^{h}\right)$. Take the point $x^{\prime} \in \alpha^{*} \subset H^{h}$ at the same distance $R^{\prime}$ from $z$. Then

$$
d\left(z^{\prime}, x^{\prime}\right) \geq D>2 \delta
$$

By Lemma 1.78, the concatenation $\beta^{*} \star \alpha^{*}$ is then an $L_{1.78}\left(R^{\prime}, \delta\right)$-quasigeodesic in $Y^{h}$.
In the next lemma we prove a generalization of this result, for concatenations of three uniform quasigeodesics.

Figure 41

Lemma 9.7. Suppose we have three $K$-quasigeodesics $\beta\left(x_{i}, y_{i}\right), \beta\left(y_{i}, y_{j}\right)$ and $\beta\left(y_{j}, x_{j}\right)$ in $Y^{h}$ such that the paths $\beta\left(x_{k}, y_{k}\right)$ are contained in the distinct peripheral horoballs $H_{k}^{h}$, and $\beta\left(y_{i}, y_{j}\right) \cap \stackrel{\circ}{H}_{k}^{h}=\emptyset, k=i, j$. (See Figure 41.) Then the concatenation

$$
\beta\left(x_{i}, y_{i}\right) \star \beta\left(y_{i}, y_{j}\right) \star \beta\left(y_{j}, x_{j}\right)
$$

is again a (uniform) $L_{9.7}(K, \delta)$-quasigeodesic in $Y^{h}$.
Proof. We first consider the concatenation $\beta\left(y_{i}, y_{j}\right) \star \beta\left(y_{j}, x_{j}\right)$ and observe that it satisfies the assumptions of Lemma 9.6 with the peripheral horoball $H^{h}$ equal $H_{j}^{h}$. Thus, $\beta=\beta\left(y_{i}, y_{j}\right) \star \beta\left(y_{j}, x_{j}\right)$ is a $K_{1}=L_{9.6}(K, \delta)$-quasigeodesic in $Y^{h}$. Then we consider the concatenation $\alpha \star \beta$, where $\alpha=\beta\left(x_{i}, y_{i}\right)$. This concatenation again satisfies the assumptions of Lemma 9.6 with the peripheral horoball $H^{h}$ equal $H_{i}^{h}$. Lemma follows.

We now analyze the nearest-point projection to quasigeodesics of the type described in Lemma 9.6:

Lemma 9.8. Consider a quasigeodesic $\gamma=\beta \star \alpha$ as in Lemma 9.6. Then for each point $p \in H^{h}$ the nearest-point projection $\bar{p}=P_{\gamma}(z)$ satisfies:

$$
d(\bar{p}, \alpha) \leq C_{9.8}(K)
$$

Proof. We continue with the notation of Lemma 9.6. Suppose that $\bar{p} \in \beta$. Since $\gamma$ is a $K$-quasigeodesic, it is $\lambda=\lambda_{1.90}(\delta, K)$-quasiconvex; hence (see Lemma 1.102), the geodesic $p z$ in $Y^{h}$ passes within distance $\leq D=\lambda+2 \delta$ from $\bar{p}$. In particular, for

$$
r=D+\lambda_{9.2}(\delta),
$$

$d\left(\bar{p}, H^{h}\right) \leq r$, i.e. $\bar{p} \in N_{r}(H)$. We also have $p \in H$ and $\beta \cap H \quad \emptyset$. Hence, according to Lemma 9.3(2) the distance between $\bar{p}$ and $z$ is $\leq 2 K$.

Lemma 9.9. The peripheral horoballs $H_{i}^{h}, i \in I$, are uniformly pairwise cobounded in $Y^{h}$.

Proof. Consider two distinct peripheral horoballs $H_{i}^{h}, H_{j}^{h}$ and suppose that $z_{i} \in H_{i}, z_{j} \in$ $H_{j}$ are within distance $c$ from each other in $Y^{h}$. The points $z_{i}, z_{j}$ are connected by a path $\beta$ of length $\leq K=4 e^{c}$ in $Y$. Hence, $\beta$ is a $K$-quasigeodesic in $Y^{h}$. Let $\rho_{i}, \rho_{j}$ denote the vertical geodesic rays in $H_{i}^{h}, H_{j}^{h}$ emanating from $z_{i}, z_{j}$ respectively. Then, by Lemma 9.7, the concatenation $\alpha$ of the rays $\rho_{i}, \rho_{j}$ and the path $\beta$ is an $L=L_{9.7}(K, \delta)$-quasigeodesic in $Y^{h}$.

Figure 42
Suppose now that we have four points $z_{i}, z_{i}^{\prime} \in H_{i}, z_{j}, z_{j}^{\prime} \in H_{j}$ satisfying $d_{Y^{h}}\left(z_{i}, z_{j}\right) \leq c$, $d_{Y^{h}}\left(z_{i}^{\prime}, z_{j}^{\prime}\right) \leq c$. We then, as above, form two $L$-quasigeodesic lines $\alpha, \alpha^{\prime}$ in $Y^{h}$ passing through the points $z_{i}, z_{j}$ and $z_{i}^{\prime}, z_{j}^{\prime}$ respectively and asymptotic to the centers $\xi\left(H_{i}^{h}\right), \xi\left(H_{j}^{h}\right)$ of our peripheral horoballs. Thus, the $\delta$-hyperbolicity of $Y^{h}$, and the fact that $\alpha, \alpha^{\prime}$ are $L$-quasigeodesics in $Y^{h}$ asymptotic to the same pairs of points at infinity, imply that the Hausdorff distance between these quasigeodesics is $\leq D=D_{1.85}(L, \delta)$, see Lemma 1.85.

We claim a uniform upper bound on the distance between $z_{i}, z_{i}^{\prime}$. By Lemma 9.8, there exists a point $x_{i} \in \rho_{i}$ within distance $C=C_{9.8}(L)$ from the nearest-point projection $\bar{z}_{i}^{\prime}$ of $z_{i}$ to $\alpha^{\prime}$. Hence,

$$
d\left(z_{i}^{\prime}, x_{i}\right) \leq D^{\prime}=D+C
$$

By the upper bound $\operatorname{Hd}\left(\alpha, \alpha^{\prime}\right) \leq D$, in view of Lemma 9.8, there exists a point $x_{i} \in$ $\rho_{i}$ within distance $D^{\prime}=D_{9.8}^{\prime}(L, D)$ from $z_{i}^{\prime}$. Since $z_{i}$ is the point in $H_{i}$ closest to $x_{i}$, it follows that $d\left(x_{i}, z_{i}\right) \leq D^{\prime}$ as well. Combining the inequalities, we get $d\left(z_{i}, z_{i}^{\prime}\right) \leq 2 D^{\prime}$. Similarly, $d\left(z_{j}, z_{j}^{\prime}\right) \leq 2 D^{\prime}$. Uniform quasiconvexity of the horoballs $H_{i}^{h}, H_{j}^{h}$ combined with Proposition 1.137 now implies that these horoballs are uniformly cobounded.

Lemma 9.10. Every point $\xi \in \partial_{\infty} Y^{h}$ is the limit of a sequence $\left(z_{n}\right)$ in $Y$, unless $\xi$ is the center of a horoball $H^{h}$ with bounded horosphere $H$.

Proof. There are two cases to consider.

1. $\xi=\xi\left(H^{h}\right)$ is the center of a peripheral horoball $H^{h}$. Fix a base-point $y_{0} \in H$ and the vertical ray $\rho$ in $H^{h}$ emanating from $y_{0}$. Since $H$ is unbounded, take a sequence $z_{n} \in H$ which diverges to infinity, i.e. $D_{n}=d_{H}\left(y_{0}, z_{n}\right) \rightarrow \infty$. We claim that $\left(z_{n}\right)$ converges to $\xi$. Indeed, for $y_{n}:=\left(z_{n}, \log \left(D_{n}\right)\right) \in H^{h}$, the combing path $c\left(y_{0}, y_{n}\right)$ in $H^{h}$ contains the subsegment of length $\log \left(D_{n}\right)$ in $\rho$. Hence, $\lim _{n \rightarrow \infty} z_{n}=\lim _{n \rightarrow \infty} \rho\left(\log \left(D_{n}\right)\right)=\xi$.
2. $\xi$ is not the center of any peripheral horoball. Then each geodesic ray $\rho=y \xi$ will cross into $Y$ along a sequence $z_{n}$ which diverges to infinity. Thus, $\left(z_{n}\right)$ converges to $\xi$.
9.1.3. Electrification and hyperbolization of quasigeodesics. In this section we describe two procedures of converting paths in $Y^{h}$ to paths in $Y^{\ell}$ and vice-versa.

We first describe the procedure of electrification of continuous hyperbolic quasigeodesics. In view of Corollary 9.5, for each continuous $K$-quasigeodesic $\beta:[0, T] \rightarrow Y^{h}$ we obtain a maximal collection of maximal pairwise disjoint subintervals $\left[s_{1}, t_{1}\right], \ldots,\left[s_{n}, t_{n}\right]$ in $[0, T]$ satisfying the assumptions of Corollary 9.5 with respect to certain peripheral subspaces $H_{j_{1}}, \ldots, H_{j_{n}} \in \mathcal{H}$. We then perform the following electrification procedure on $\beta$ :

For each subinterval $\left[s_{i}, t_{i}\right]$ we replace the restriction of $\beta$ to $\left[s_{i}, t_{i}\right]$ with the concatenation of two geodesic segments (of length $1 / 2$ each) in $H_{j_{i}}^{\ell}$ connecting $\beta\left(s_{i}\right), \beta\left(t_{i}\right)$ to the apex $a\left(H_{j_{i}}^{\ell}\right)$ of the cone $H_{j_{i}}^{\ell}$. In the special case when we have to deal with the subintervals [ $0, t_{1}$ ] and/or $\left[s_{n}, T\right]$ (i.e, $\beta(0)$ or $\beta(T)$ belongs to one of the open horoballs $\dot{H}_{j}^{h}$ ), we replace $\left.\beta\right|_{\left[0, t_{1}\right]}$ (resp. $\left.\beta\right|_{\left[s_{n}, T\right]}$ ) with the unit length geodesic in $H_{j}^{\ell}$ connecting the apex $a\left(H_{j}^{\ell}\right)$ to $\beta\left(t_{1}\right)$ (resp. $\beta\left(s_{n}\right)$ ). We let $\beta^{\ell}$ denote the resulting path in $X^{\ell}$. Lastly, each subpath of $\beta$ whose domain has length $\leq 2 L(K)$ and which connects points of $H_{i}$ in $H_{i}^{h}$, is replaced by a geodesic in $H_{i}$ connecting the same points. Lengths of such geodesics are uniformly bounded by some constant $E=E(K)$ since horospheres $H_{i}$ are uniformly properly embedded in the horoballs $H_{i}^{h}$. The resulting map $\beta^{\ell}=\mathcal{E}_{\mathcal{P}}(\beta)$ will be called the electrification of $\beta$.

We note that $\beta^{\ell}$ visits each cone-point $a\left(H_{j_{i}}^{\ell}\right), i=1, \ldots, n$, exactly once; more precisely, $\beta^{\ell}$ is tight in the following sense:

Definition 9.11. A continuous path $\gamma$ in $Y^{\ell}$ is tight if for each cone $H_{i}^{\ell}, i \in I$, the preimage $\gamma^{-1}\left(\stackrel{H}{H}_{i}^{\ell}\right)$ is a (possibly empty) interval and the restriction of $\gamma$ to this interval is 1-1.

Remark 9.12. 1. The commonly used name for tight paths is paths without backtracking; we find this terminology cumbersome.
2. The continuity assumption here is simply a matter of convenience and electrification can be defined for general $K$-quasigeodesics by using $s_{i}, t_{i}$ 's such that $\beta\left(s_{i}\right), \beta\left(t_{i}\right)$ are within distance $K$ from the horosphere $H_{i}$.
3. The electrification procedure described in [DM17] is similar, except they replace by geodesics in $H_{i}^{\ell}$ the subsegments in $\beta$ with end-point in $H_{i}$ at distance $>1$. This construction, while technically simpler, does not result in tight paths, which we find undesirable.

More generally, we define tightness of paths in $Y^{h}$ as follows:
Definition 9.13. We say that a continuous path $\beta$ in $Y^{h}$ is tight (relative to $\mathcal{H}$ ) if for each peripheral horoball $H \in \mathcal{H}$, the preimage $\beta^{-1}\left(H^{h}\right)$ is an open interval (possibly empty).

It is clear that for each tight path $\beta$, its electrification $\beta^{\ell}$ is a tight path in $Y^{\ell}$.
We next use electrification to compare distances in $Y^{h}$ and in $Y^{\ell}$ :
Lemma 9.14. For any two pair of points $x, y \in Y, d^{\ell}(x, y) \leq d_{Y^{h}}(x, y)$, i.e. the inclusion $\operatorname{map}\left(Y, d_{Y^{h}}\right) \rightarrow\left(Y^{\ell}, d^{\ell}\right)$ is 1-Lipschitz.

Proof. Recall that by the definition of the metric on the hyperbolic cones $H_{i}^{h}$, if $x, y$ belong to the same peripheral subspace $H_{i}$ and $d_{Y^{h}}(x, y) \leq 1$, then $d_{Y}(x, y) \leq 1$. It follows that if $\beta$ is a geodesic in $Y^{h}$ connecting the points $x, y \in Y$ then the length of $\beta^{\ell}$ is at most the length of $\beta$.

Hyperbolization of electric geodesics. Conversely, given any (continuous) path $\beta$ in $Y^{\ell}$, we define its hyperbolization $\beta^{h}$ by replacing each subpath $\beta_{H}$ of $\beta$ connecting $x, y \in$ $H \in \mathcal{H}$ and contained in $\stackrel{H}{H}^{\ell}$ except for its end-points, with the combing path $c(x, y)$ in $H^{h}$, see Section 1.11. Recall that the paths $c(x, y)$ are uniform quasigeodesics in $H^{h}$ (with respect to the intrinsic metric $d^{h}$ on $H^{h}$ ). It is clear that if $\beta$ was tight, so is $\beta^{h}$.

In the case when $\beta$ is a quasigeodesic in $Y^{\ell}$, the path $\beta^{h}$ is called an electro-ambient quasigeodesic, see [DM17]. This construction yields a collection of paths in $Y^{h}$ connecting points in $Y$. In Section 9.2 .1 we describe (uniform) electro-ambient quasigeodesics connecting arbitrary pairs of points in $Y^{h}$.

The next result appears in [DM17, Lemma 2.15].
Lemma 9.15. For tight ${ }^{1}$ uniform quasigeodesics $\beta$ in $Y^{\ell}$ connecting points of $Y$, the paths $\beta^{h}$ are uniform quasigeodesics in $Y^{h}$. More precisely, there exists a function $L=$ $L_{9.15}(K)$ such that if $\beta$ is a tight $K$-quasigeodesic in $Y^{\ell}$ connecting points of $Y$, its hyperbolization $\beta^{h}$ is an L-quasigeodesic in $Y^{h}$.

An alternative and detailed proof was given by A. Pal and A. Kumar Singh in [PKS15]; we will discuss this further in Section 9.2.1.

### 9.2. Hyperbolicity of the electric space

In this section we will prove that for each relatively hyperbolic space $(Y, \mathcal{H})$, the space $Y^{\ell}$ is hyperbolic and describe uniform quasigeodesics in this space. The key result of this section is:

Proposition 9.16. Electrifications $\alpha^{\ell}$ of uniform (continuous) quasigeodesics $\alpha$ in $Y^{h}$ connecting points of $Y$, are uniformly proper in $Y^{\ell}$.

[^17]Proof. Let $\alpha: J=[0, T] \rightarrow Y^{h}$ be a continuous $K$-quasigeodesic in $Y^{h}$ connecting points $x, y \in Y$. Our goal is to prove that the length of the domain of $\alpha^{\ell}$ is bounded in terms of the distance $M:=d^{\ell}(x, y)$. This will imply uniform properness of the maps $\alpha^{\ell}$ for all continuous $K$-quasigeodesics $\alpha$ in $Y^{h}$.

Let $\beta$ be a geodesic in $Y^{\ell}$ connecting $x$ to $y$ and the length of $\beta$ is $\leq M$. In particular, $\beta$ goes through at most $N$ cones $H_{i}^{\ell}$ where $N$ depends only on $M$; these cones correspond to the horoballs $B_{1}=H_{i_{1}}^{h}, \ldots, B_{n}=H_{i_{n}}^{h}$ in $Y^{h}, n \leq N$. It also follows that the length of each subsegment of $\beta$ between two distinct horoballs is at most $M$. By renumbering the horoballs, we can also label these subsegments $\beta_{1}, \ldots, \beta_{n-1}$ so that $\beta_{i}$ connects $B_{i}$ to $B_{i+1}$. We also label $\beta_{0}$ the subsegment of $\beta$ between $x$ and $B_{1}$ and label $\beta_{n}$ the subsegment of $\beta$ between $B_{n}$ and $y$. Set

$$
B:=\beta_{0} \cup B_{1} \cup \ldots \cup B_{n} \cup \beta_{n} .
$$

In particular, the subset $B \subset Y^{h}$ is $\lambda=\lambda(M)$-quasiconvex in $Y^{h}$. According to Lemma 1.139 , there exists $D$ and $\epsilon$ such that for each component $C$ of $\alpha^{-1}\left(Y^{h}-N_{D}(B)\right)$ the projection of $\alpha(C)$ to $B$ has diameter $\leq \epsilon$. (Here $\epsilon, D$ depend on $\delta, K$ and $\lambda$, and $D=$ $D_{1.139}\left(\delta, \lambda^{\prime}\right)$, where $\lambda^{\prime}$ is the maximum of $\lambda$ and the quasiconvexity constant of the images of $K$-quasigeodesics in $Y^{h}$.) We now decompose the interval $J=[0, T]$ according to the mutual position of points $\alpha(t), t \in J$, with respect to the horoballs $B_{i}$ and the segments $\beta_{i}$.

Let $J\left(\beta_{j}\right)$ denote the maximal subinterval in $J$ such that the images of the end-points of $J\left(\beta_{j}\right)$ under $\alpha$ belong to $N_{D}\left(\beta_{j}\right)$. Similarly, we define subintervals $J\left(B_{j}\right)$.

1. Since $\alpha$ is a $K$-quasigeodesic and $\beta_{j}$ has length $\leq M$, the length of each $J\left(\beta_{j}\right)$ is $\leq K(2 D+M+1)$.
2. Similarly, Lemma 9.3 implies that the length of each $J\left(B_{j}\right) \backslash \alpha^{-1}\left(B_{j}\right)$ is at most $2 L_{9.3}(K+D, 0, \delta)$. Recall that by the definition of $\alpha^{\ell}$, whenever $J\left(B_{j}\right) \backslash \alpha^{-1}\left(B_{j}\right)$ is nonempty, the interval $J\left(B_{j}\right)$ contributes the length $\leq 2+2 L_{9.3}(K+D, 0, \delta)$ to the length of the domain of $\alpha^{\ell}$.
3. It now remains to estimate the length of

$$
J^{\prime}:=J \backslash \bigcup_{i=0}^{n+1}\left(J\left(\beta_{i}\right) \cup J\left(B_{i}\right)\right)
$$

Let $C=[s, t]$ be a component of this complement. Then both points $\alpha(s), \alpha(t)$ belong to $\partial N_{D}(B)$ and the diameter of the projection of $\alpha(C)$ to $B$ is $\leq \epsilon$. Hence, the distance in $Y^{h}$ between $\alpha(s), \alpha(t)$ is at most $2 D+\epsilon$. It follows that $C$ has length $\leq K(2 D+\epsilon+1)$. Since the number of components $C$ is $\leq 2 N+2$, it follows that the total length of $J^{\prime}$ is at most

$$
K(2 D+\epsilon+1)(2 N+2) .
$$

Combining these estimates we conclude that the domain of $\alpha^{\ell}$ has length at most

$$
(M+1) K(2 D+M+1)+\left(2+2 L_{9.3}(K+D, 0, \delta)\right) M+K(2 D+\epsilon+1)(2 N+2) .
$$

Uniform properness of the maps $\alpha^{\ell}$ follows.
As an application of this result we prove:
Theorem 9.17. I. If $(Y, \mathcal{H})$ is relatively hyperbolic, then $Y^{\ell}$ is hyperbolic.
2. Moreover, continuous $K$-quasigeodesics $\alpha$ in $Y^{h}$ yield $k_{9.17}(K)$-quasigeodesics $\alpha^{\ell}$ in $Y^{\ell}$.

Proof. We will verify that the conditions of Corollary 1.64 are met. Namely, we will check that the combing of $Y^{h}$ by continuous $K$-quasigeodesics $\alpha$ results in a thin combing of $Y^{\ell}$ by paths $\alpha^{\ell}$ connecting points of the subset $Y_{0}^{\ell} \subset Y^{\ell}$ which is the union of $Y$ and
the set $a\left(Y^{\ell}\right)$ of apexes $a_{i}$ of the cones $H_{i}^{\ell}, i \in I$. We already know that the paths $\alpha^{\ell}$ are uniformly proper (Property 1 in Corollary 1.64). Let us verify Property 2. Consider a triple of $K$-quasigeodesics $\alpha_{x, y}, \alpha_{y, z}, \alpha_{z, x}$ connecting points $x, y, z$ in $Y^{h}$. Since $Y^{h}$ is $\delta$-hyperbolic,

$$
\alpha_{x, y} \subset N_{3 D_{1.53}(\delta, K)+\delta}\left(\alpha_{y, z} \cup \alpha_{z, x}\right) .
$$

Let $u$ be a point of $\alpha_{x, y} \cap Y$ and suppose that $v$ is a point in $\alpha_{y, z}$ at a distance $d_{Y^{h}}(u, v) \leq$ $3 D_{1.53}(\delta, K)+\delta$ from $u$. If $v$ happens to be in $Y$, then Lemma 9.14 implies that

$$
d^{\ell}(u, v) \leq 3 D_{1.53}(\delta, K)+\delta
$$

as well. If $v=\alpha_{y, z}(t)$ belongs to an open horoball $\stackrel{\circ}{H}_{i}^{h}$ but $t$ does not lie in one of the subintervals $\left[s_{i}, t_{i}\right]$ in the domain of the path $\alpha_{y, z}$ which are coned-off when we define $\alpha_{y, z}^{\ell}$, then the distance in $Y^{h}$ from $\alpha_{y, z}(t)$ to $\alpha_{y, z} \cap H_{i}$ is at most $2(K+1) L_{9.3}(K, 0, \delta)$ and, thus, $d^{\ell}\left(u, \alpha_{y, z}\right) \leq 2(K+1) L_{9.3}(K, 0, \delta)$ as well. Lastly, if $t$ is one of the intervals $\left[s_{i}, t_{i}\right]$ then $p_{i}$ is in $\alpha_{y, z}$ and $d^{\ell}\left(u, p_{i}\right) \leq d(u, v)+1 \leq 3 D_{1.53}(\delta, K)+\delta+1$.

Finally, each point of $\alpha_{x, y}^{\ell}$ lies within unit distance (as measured in $Y^{\ell}$ ) from a point of $\alpha_{x, y}^{\ell} \cap Y$ and, therefore, for

$$
R=3 D_{1.53}(\delta, K)+\delta+1+2(K+1) L_{9.3}(K, 0, \delta),
$$

the path $\alpha_{x, y}^{\ell}$ is contained in the $R$-neighborhood (in $Y^{\ell}$ ) of the union $\alpha_{y, z}^{\ell} \cup \alpha_{z, x}^{\ell}$.
The following consequence of the theorem appears in [Kla99, Proposition 4.3], see also [Far98, Lemma 4.5 and Lemmas 4.8, 4.9] in the setting of manifolds of negative curvature:

Corollary 9.18. For $x, y \in Y$ let $\alpha=[x y]_{Y^{t}}$ and $\beta=[x y]_{Y^{h}}$. Then the Hausdorff distance in $Y$ between $\alpha \cap Y$ and $\beta \cap Y$ is uniformly bounded.

Proof. 1. Take $z \in \alpha \cap Y$. Since $\alpha^{h}$ is a uniform $k$-quasigeodesic in $Y^{h}$ connecting the endpoints of $\beta$, the $k$-quasigeodesics $\alpha^{h}$ and $\beta$ are $D$-Hausdorff-close in $Y^{h}, D=D_{1.53}(\delta, k)$. Thus, there exists $w \in \beta$ within distance $D$ from $z$. If $w$ happens to be in $Y$, we are done. Suppose, therefore, that $w \in H$ for some $H \in \mathcal{H}$. Since $w$ is within distance $D$ (as measured in $Y^{h}$ ) from $Y$, and $\beta$ is a geodesic in $Y^{h}$, it follows that there exists a point $v \in \beta \cap H$ within distance $C=D+D^{\prime}$ from $w$, where $D^{\prime}=D_{1.53}(\delta, K)$ and $K$ is the qi constant of the combing paths in $H^{h}$. Since $d_{Y^{h}}(v, z) \leq D+C$, it follows that $d_{Y}(v, z)$ is also uniformly bounded by a uniform constant $E$, as $(Y, d)$ is uniformly properly embedded in $\left(Y^{h}, d^{h}\right)$, see Lemma 9.2(2). Hence,

$$
\alpha \cap Y \subset N_{E}^{Y}(\beta \cap Y)
$$

2. The proof of the opposite inclusion is similar, swapping the roles of $\alpha^{h}$ and $\beta$ and is left to the reader.

We also record another application of Theorem 9.17:
Corollary 9.19. There exists a constant $L=L_{9.19}(\delta)$ such that every two points $x, y$ is $X$ are connected by a tight L-quasigeodesic in $X^{\ell}$. Namely, given a geodesic $c=[x y]_{X^{h}}$ in $X^{h}$, its electrification $c^{\ell}$ is a uniform tight quasigeodesic in $X^{\ell}$.

We define a coarse projection $q=q_{Y}: Y^{h} \rightarrow Y^{\ell}$ as follows:

1. The map $q$ is the identity on $Y$.
2. For each peripheral subspace $H_{i}, q\left(\stackrel{\circ}{H}_{i}^{h}\right)=\left\{a\left(H_{i}^{\ell}\right)\right\}$, the apex of the cone over $H_{i}$.

The following lemma is immediate:
Lemma 9.20. The map $q$ is $(1,1)$-coarse Lipschitz.

The next result is a direct corollary of Theorem 9.17(2):
Corollary 9.21. There exists a function $\lambda \mapsto \hat{\lambda}$ such that if $Z \subset Y^{h}$ is a $\lambda$-quasiconvex subset, then $q(Z)$ is $\hat{\lambda}$-quasiconvex in $Y^{\ell}$.

Lemma 9.22. The projection q coarsely commutes with nearest-point projections. More precisely, there is $D=D_{9.22}(\delta, \lambda)$, where $\delta$ is the hyperbolicity constant of $Y^{h}$, such that for each $\lambda$-quasiconvex subset $Z \subset Y^{h}$,

$$
d\left(P_{Y^{\ell}, q(Z)}, q \circ P_{Y^{n}, Z}\right) \leq D .
$$

Proof. For $y \in Y^{h}$, up to a uniformly bounded error, the projection $\bar{y}=P_{Y^{h}, Z}(y)$ of $y$ to $Z$ is defined by the property that for each $z \in Z$ the concatenation $\beta=y \bar{y} \star \bar{y} z=\beta_{1} \star \beta_{2}$ is a uniform quasigeodesic (see Lemma 1.102). Suppose first that $\bar{y} \in Y$. Theorem 9.17(2) implies that the concatenation $\beta^{\ell}=\beta_{1}^{\ell} \star \beta_{2}^{\ell}$ is a uniform quasigeodesic in $\hat{Y}$. By applying Lemma 1.98, we conclude that $\bar{y}$ is uniformly close to $P_{Y^{\ell}, q(Z)}(q(y))$.

Suppose now that $\bar{y}$ lies in some $H_{i}^{h}$; let $a_{i}=a\left(H_{i}^{h}\right)$ denote the apex of the cone in $Y^{\ell}$ corresponding to $H_{i}$, and $\beta_{0} \subset H_{i}^{h}$ be the maximal subsegment of $\beta$ contained in $H_{i}^{h}$ and connecting points $x_{i}, y_{i} \in H_{i}$. Then $\beta$ is the concatenation $\beta_{1} \star \beta_{0} \star \beta_{2}$. Accordingly, $\beta^{\ell}$ is the concatenation $\beta_{1}^{\ell} \star\left[x_{i} a_{i}\right] \star\left[a_{i} y_{i}\right] \star \beta_{2}^{\ell}$. Thus, $a_{i}$ is uniformly close to $P_{Y^{\ell}, q(Z)}(q(y))$. At the same time, $q(\bar{y})=a_{i}$.

Lastly, we discuss relatively hyperbolic structures on metric spaces which are already hyperbolic, see [Far98]:

Theorem 9.23. Suppose that $X$ is a hyperbolic space and $\mathcal{H}=\left\{H_{i}, i \in I\right\}$ is a collection of uniformly pairwise cobounded uniformly quasiconvex subsets in $X$. Then:

1. The pair $(X, \mathcal{H})$ is relatively hyperbolic.
2. Conversely, if $X$ is hyperbolic and $\mathcal{H}=\left\{H_{i}, i \in I\right\}$ is a collection of uniformly quasiconvex subsets, and $X^{h}$ is hyperbolic, then the subsets $\left\{H_{i}, i \in I\right\}$ are uniformly pairwise cobounded in $X$.

Proof. 1. We first equip $X^{h}$ with a structure of a tree of hyperbolic spaces $\left.\mathfrak{Y}\right)=(\pi$ : $Y \rightarrow T)$. We define the tree $T$ by taking the wedge of rays $R_{i}, i \in I$, where each $R_{i}$ is the positive half-line $[0, \infty)$ equipped with the standard simplicial structure (vertices are the nonnegative integers) and the wedge of rays is obtained by identifying 0 'es in all $R_{i}$ 's with a single vertex $v_{0} \in T$. For $n \in \mathbb{N} \subset R_{i}$ we use the notation $v_{i n}$ for the corresponding vertex in $T$. We define vertex-spaces of $\mathfrak{Y}$ as $Y_{v_{0}}:=X ; Y_{v_{i n}}:=H_{i} \times\{n\} \subset H_{i}^{h}=H_{i} \times[1, \infty)$. The edge-space $Y_{e_{i n}}$ for the edge $e_{i n}=\left[v_{i n}, v_{i n+1}\right]$ is $H_{i} \times\left\{n+\frac{1}{2}\right\}$. The incidence maps

$$
f_{e_{i n}, v_{i n}}: Y_{e_{i n}} \rightarrow Y_{v_{i n}}, f_{e_{i n}, v_{i n+1}}: Y_{e_{i n}} \rightarrow Y_{v_{i n+1}}
$$

are given by

$$
\left(y, n+\frac{1}{2}\right) \mapsto(y, n), \quad\left(y, n+\frac{1}{2}\right) \mapsto(y, n+1)
$$

respectively. These maps clearly are uniform quasiisometries. Thus, we obtain a tree of hyperbolic spaces $\mathfrak{Y})=(\pi: Y \rightarrow T)$.

Since the hyperbolic cones $H_{i}^{h}$ are uniformly hyperbolic (see Proposition 1.68), the restrictions of the tree of spaces $\mathfrak{Y}$ ) to the rays $R_{i}$ satisfy the uniform flaring condition with flaring constants independent of $i$, see Lemma 2.46. Suppose that $\llbracket v, w \rrbracket \subset T$ is an interval containing vertices (different from $v_{0}$ ) of different rays $R_{i}, R_{j}$. Let $\gamma_{0}, \gamma_{1}$ be $K$-qi sections of $\pi: Y \rightarrow T$ over $\llbracket v, w \rrbracket$. The assumption that peripheral subspaces $H_{i}, H_{j}$ in $X$ are uniformly cobounded implies that

$$
d_{Y_{v_{i 1}}}\left(\gamma_{0}\left(v_{i 1}\right), \gamma_{1}\left(v_{i 1}\right)\right) \leq C(K), \quad d_{V_{v_{j 1}}}\left(\gamma_{0}\left(v_{j 1}\right), \gamma_{1}\left(v_{j 1}\right)\right) \leq C(K)
$$

In view of the uniform flaring of $\mathfrak{Y}$ ) over the rays $R_{i}, R_{j}$, it then follows that

$$
d_{Y_{v_{i n}}}\left(\gamma_{0}\left(v_{i 1}\right), \gamma_{1}\left(v_{i n}\right)\right)
$$

is either uniformly bounded (in terms of $K$ ) or grows at a linear rate (as a function of $n$ ). The same applies to

$$
d_{V_{v_{j n}}}\left(\gamma_{0}\left(v_{j 1}\right), \gamma_{1}\left(v_{j n}\right)\right) .
$$

Hence $\mathfrak{Y}$ ) satisfies the uniform flaring condition and, thus, $Y$ is uniformly hyperbolic by Theorem 2.58.
2. This part is a consequence of Lemma 9.9.

This theorem has a useful addendum, relating quasigeodesics in $X$ and in $X^{h}$. In the setting of the theorem, let $\beta$ be a $k$-quasigeodesic in $X^{h}$ connecting points in $X$. For each maximal subsegment $\beta_{i}$ contained in some $H_{i}^{h}$, we replace $\beta_{i}$ with a geodesic in $X$ connecting the end-points of $\beta_{i}$. We let $\beta_{X}$ denote the resulting path in $X$.

Lemma 9.24. The paths $\beta_{X}$ in $X$ are $K_{9.24}(k)$-quasigeodesic.
Proof. Thinking of $X^{h}$ as the total space $Y$ of a tree of spaces $\mathfrak{Y}$ as above, we note that the path $\beta_{X}$ obtained via the above procedure of converting $\beta$ to $\beta_{X}$ is exactly the cut-andreplace procedure in Definition 8.12. Now, the result follows from Theorem 8.19 (actually, it follows already from Proposition 8.20 proven earlier by Mitra in [Mit98]).
9.2.1. Equivalence of the two definitions of relative hyperbolicity. We start by reviewing Farb's definition of relative hyperbolicity. Given a metric space $Y$ and a collection of its rectifiably connected, uniformly properly embedded subspaces $\mathcal{H}=\left\{H_{i}: i \in I\right\}$, we get the associated electric space $Y^{\ell}=\mathcal{E}(Y, \mathcal{H})$ with the metric $d^{\ell}$ as described in Section 9.1.1.

Definition 9.25. The pair $(Y, \mathcal{H})$ is said to be weakly relatively hyperbolic if the metric space $\left(Y^{\ell}, d^{\ell}\right)$ is hyperbolic.

Every two points in $Y^{\ell}$ are connected by a tight $L$-quasigeodesic in $Y^{\ell}$ for some uniform constant $L$ (for instance, one can use geodesics in $Y^{\ell}$ ). We refer to the tight quasigeodesics in $Y^{\ell}$ connecting points in $Y$ as electric quasigeodesics in $Y^{\ell}$.

In Section 9.1.1, given an electric quasigeodesic $\beta$ in $Y^{\ell}$ connecting points $x, y \in Y$, we defined a path $\beta^{h}$ in $Y^{h}$ (the hyperbolization of $\beta$ ) connecting $x$ and $y$. We now extend this definition to connect arbitrary pairs of points $x, y$ in $Y^{h}$. We let $\hat{x}=q(x), \hat{y}=q(y)$ denote the projections of $x, y$ to $Y^{\ell}$. Let $\beta$ be an electric quasigeodesic connecting $\hat{x}$ to $\hat{y}$. In the case when $x \in \stackrel{\circ}{H}^{h}, \hat{x}=a\left(H^{\ell}\right)$ is the apex of the cone $H^{\ell}$, we let $x_{H} \in H$ denote the exit point of $\beta$ from the cone $H^{\ell}$; similarly, if $y \in H^{h}$, we let $y_{H}$ denote the entry point of $\beta$ into the cone $H^{\ell}$. We set $x^{\prime}=x$ if $x \in Y$ and $x^{\prime}:=x_{H}$ if $x \notin Y$; similarly, we define the point $y^{\prime}$. Then for the subpath $\beta\left(x^{\prime}, y^{\prime}\right)$ of $\beta$ between $x^{\prime}, y^{\prime}$, we define its hyperbolization $\beta\left(x^{\prime}, y^{\prime}\right)^{h}$ as before, and connect $x$ to $x^{\prime}, y$ to $y^{\prime}$ by geodesics in the corresponding horoballs $H^{h}$ in the case when $x \neq x^{\prime}$ or $y \neq y^{\prime}$.

We, thus, obtain a family of paths connecting points of $Y^{h}$. As it turns out (see Theorem 9.28), under suitable assumptions, the resulting paths define a slim combing of $Y^{h}$. In the next definition, $D=D(K)$.

Definition 9.26. Two electric $K$-quasigeodesics $\alpha_{1}, \alpha_{2}$ with the same end-points are said to have the same $D$-intersection pattern with respect to the collection of cones $H_{i}^{\ell}, i \in$ $I$, or, simply, $D$-track each other, if the following conditions hold for all $i \in I$ :

1. If one path, say, $\alpha_{1}$, contains $a\left(H_{i}^{\ell}\right)$ but then other (namely, $\alpha_{2}$ ) does not, then $d_{H_{i}}\left(\alpha_{1}(s), \alpha_{1}(t)\right) \leq D$, where $\alpha_{1}^{-1}\left(\stackrel{H}{H}_{i}^{\ell}\right)$ is the open interval $(s, t)$.
2. Suppose that, for some $i \in I, \alpha_{j}^{-1}\left(\dot{H}_{i}^{\ell}\right)=\left(s_{i}, t_{i}\right) \neq \emptyset, j=1,2$. Then

$$
\max \left\{d_{H_{i}}\left(\alpha_{1}\left(s_{1}\right), \alpha_{2}\left(s_{2}\right)\right), d_{H_{i}}\left(\alpha_{1}\left(t_{1}\right), \alpha_{2}\left(t_{2}\right)\right)\right\} \leq D
$$

The function $D(K)$ is the tracking function of $(Y, \mathcal{H})$.
Definition 9.27. A pair $(Y, \mathcal{H})$ is relatively hyperbolic in Farb's sense $(F R H)$ if it is weakly relatively hyperbolic and for every $K \geq 1$ there exists $D=D(K)$ such that any two electric $K$-quasigeodesics with the same end-points $D$-track each other.

The next theorem relating the two definitions was proven by A. Pal and A. Kumar Singh in [PKS15] (for relatively hyperbolic groups the equivalence of two definitions was known earlier, cf. [Bow12]):

Theorem 9.28. If $(Y, \mathcal{H})$ is $F R H$, then $Y^{h}$ is uniformly ${ }^{2}$ hyperbolic and the hyperbolization of uniform electric quasigeodesics yields uniform quasigeodesics in $Y^{h}$. In particular, $(Y, \mathcal{H})$ is GRH.

Remark 9.29. A. Pal and A. Kumar Singh in [PKS15] assume that the subsets $H_{i}, i \in$ $I$, are uniformly separated in $Y$. In our setting one achieves uniform separation by replacing $Y$ with the space $Y^{\prime}$ obtained by attaching the products $H_{i} \times[0,1], i \in I$, along the subsets $H_{i}$, and replacing the subsets $H_{i} \subset Y$ with $H_{i} \times\{1\}, i \in I$.

To conclude the discussion, we note a relation between uniform tight quasigeodesics in $Y^{\ell}$ and uniform quasigeodesics in the space $Y$ itself. (This is not needed for any proofs in the book, but clarifies the overall picture.) The following result is proven in [Hru10, Lemma 8.8] in the context of relatively hyperbolic groups, but the proof works for general relatively hyperbolic spaces:

Theorem 9.30. There are functions $D=D_{9.30}(K, \delta)$ and $L=L_{9.30}(K, \delta)$ such that if $\alpha$ is an electric $K$-quasigeodesic in $Y^{\ell}$ (connecting points $x, y$ of $Y$ ), then for every $L$ quasigeodesic $\beta$ in $Y$ also connecting $x$ and $y$, we have that $\alpha \cap Y$ is contained in the $D$-neighborhood of $\beta$, with respect to the metric $d_{Y}$ of $Y$.
9.2.2. Morphisms of relatively hyperbolic spaces. Given a pair of relatively hyperbolic spaces $(Y, \mathcal{H}),\left(Y^{\prime}, \mathcal{H}^{\prime}\right)$, a relative morphism of these pairs is a uniformly proper map $f: Y \rightarrow Y^{\prime}$ such that:
a. For each $H^{\prime} \in \mathcal{H}^{\prime}, f^{-1}\left(H^{\prime}\right)$ is either empty or equals some $H \in \mathcal{H}$.
b. For each $H \in \mathcal{H}$, there exists $H^{\prime} \in \mathcal{H}^{\prime}$ satisfying $f(H) \subset H^{\prime}$.

Remark 9.31. 1. The first condition implies that if $H_{i}, H_{j} \in \mathcal{H}$ are distinct, then $f\left(H_{i}\right), f\left(H_{j}\right)$ are not contained in the same $H^{\prime} \in \mathcal{H}^{\prime}$.
2. One can relax a bit the above conditions by requiring existence of a uniform constant $D$ such that:
(a') For each $H^{\prime} \in \mathcal{H}^{\prime}, f^{-1}\left(H^{\prime}\right)$ either has diameter $\leq D$ or is $D$-Hausdorff-close to some $H \in \mathcal{H}$.
(b') For each $H \in \mathcal{H}$, there exists $H^{\prime} \in \mathcal{H}^{\prime}$ satisfying $f(H) \subset N_{D}\left(H^{\prime}\right)$.
This is the approach taken in [MS20]. However, the two definitions are easily seen to be effectively equivalent since one can replace the peripheral horoballs $H^{h}, H \in \mathcal{H}$ and $\left(H^{\prime}\right)^{h}, H^{\prime} \in \mathcal{H}^{\prime}$, by suitable smaller subsets.

[^18]A relative morphism is said to be a relative qi embedding of the pairs if, additionally: c. $f: Y \rightarrow Y^{\prime}$ is a qi embedding.

The qi constants of $f$ are called the parameters of the relative qi embedding $f$.
Given a relative morphism $f:(Y, \mathcal{H}) \rightarrow\left(Y^{\prime}, \mathcal{H}^{\prime}\right)$, the coned-off map $f^{\ell}: Y^{\ell} \rightarrow\left(Y^{\prime}\right)^{\ell}$ is defined as follows:
i. The restriction of $f^{\ell}$ to $Y$ equals $f$.
ii. Consider a peripheral subset $H \in \mathcal{H}$ such that $f(H) \subset H^{\prime} \in \mathcal{H}^{\prime}$ and let $a=$ $a\left(H^{\ell}\right), a^{\prime}=a\left(\left(H^{\prime}\right)^{\ell}\right)$ denote the respective apexes of the cones $H^{\ell},\left(H^{\prime}\right)^{\ell}$ over these peripheral subsets in $Y^{\ell},\left(Y^{\prime}\right)^{\ell}$. Then $f^{\ell}(a)=a^{\prime}$ and for each $x \in H, x^{\prime}:=f(x) \in H^{\prime}$, the map $\hat{f}$ sends the radial segment $x a$ to $x^{\prime} a^{\prime}$ isometrically. This defines $f^{\ell}$ on $H^{\ell}$ for each $H \in \mathcal{H}$.

Similarly, we define the hyperbolic extension $f^{h}$ of $f, f^{h}: Y^{h} \rightarrow\left(Y^{\prime}\right)^{h}$; this extension construction goes back to the work of Mostow on strong rigidity of nonuniform lattices in rank one Lie groups.

For $x \in H \in \mathcal{H}, x^{\prime}=f(x) \in H^{\prime} \in \mathcal{H}^{\prime}$, we consider the vertical geodesic rays $\rho_{x}:[0, \infty) \rightarrow H^{h}, \rho_{x^{\prime}}:[0, \infty) \rightarrow\left(H^{\prime}\right)^{h}$, emanating from $x, x^{\prime}$ and asymptotic to the centers of the horoball $H^{h},\left(H^{\prime}\right)^{h}$. Then for $t \in[0, \infty)$, we set

$$
f^{h}\left(\rho_{x}(t)\right):=\rho_{x^{\prime}}(t), \quad x \in H
$$

Lemma 9.32. 1. The hyperbolic extension $f^{h}$ of a proper coarse Lipschitz map is again a proper coarse Lipschitz map.
2. If $f, f^{\ell}$ are qi embeddings, then so is $f^{h}$ and the constants of $f^{h}$ depend only on the parameters of $(Y, \mathcal{H}),\left(Y^{\prime}, \mathcal{H}^{\prime}\right)$ and qi constants of $f, f^{\ell}$.
3. Conversely, if $f$ and $f^{h}$ are qi embeddings, so is $f^{\ell}$.

Proof. Part 1. We will only show that $f^{h}$ is coarse Lipschitz and leave it to the reader to check properness. Since $Y^{h}$ is a path-metric space, the problem is local and we have to address it only in the horoballs $H^{h}, H \in \mathcal{H}$. Clearly, $f^{h}$ is isometric along the vertical geodesic rays in $H^{h}$. Suppose, therefore, that $y_{1}, y_{2}$ are points within unit distance on the same horosphere $H \times\{t\} \subset H^{h}, t \geq 0$ (where the distance is computed in the intrinsic metric of the horosphere). Thus, $y_{i}=\rho_{x_{i}}(t), x_{i} \in H, i=1,2$, and, by the definition of the metric on $H^{h}$,

$$
d_{H}\left(x_{1}, x_{2}\right)=e^{t} .
$$

Since the horospheres $H, H^{\prime}$ are uniformly qi embedded in $Y, Y^{\prime}$, we conclude that the restriction map $f:\left(H, d_{H}\right) \rightarrow\left(H^{\prime}, d_{H^{\prime}}\right)$ is $(L, A)$-coarse Lipschitz, where $L, A$ depend only on the parameters of $(Y, \mathcal{H})$ and $f$. Hence,

$$
d_{H^{\prime}}\left(f\left(x_{1}\right), f\left(x_{2}\right)\right) \leq L d_{H}\left(x_{1}, x_{2}\right)+A \leq L e^{t}+A .
$$

Again, by the definition of the metric on the horoball $\left(H^{\prime}\right)^{h}$,

$$
d\left(\rho_{x_{1}^{\prime}}(t), \rho_{x_{2}^{\prime}}(t)\right) \leq e^{-t}\left(L e^{t}+A\right)=L+e^{-t} A \leq L+A .
$$

This verifies that $f^{h}$ is uniformly coarse Lipschitz.
Part 2. Note that given an ambient geodesic $\gamma$ in $Y^{h}$, its electrification $\gamma^{\ell}$ is a uniform electric quasigeodesic in $Y^{\ell}$, hence, $f^{\ell}$ carries it to a uniform electric quasigeodesic $\hat{\gamma}^{\prime}$ in $\left(Y^{\prime}\right)^{\ell}$, coarsely preserving its arc-length. Then, applying Lemma 9.15, we obtain that the hyperbolization $\gamma^{\prime}=\left(\hat{\gamma}^{\prime}\right)^{h}$ of $\hat{\gamma}^{\prime}$ is a uniform quasigeodesic in $\left(Y^{\prime}\right)^{h}$. By the construction, the map $f^{h}$ coarsely preserves arc-lengths of paths in $X^{h}$, cf. Section 1.11; and, thus, $f^{h}$ sends geodesics to uniform quasigeodesics coarsely preserving arc-length, hence, is a qi embedding.

Part 3. The proof of this part is similar to the proof of Part 2, except one uses Theorem 9.17(2).

Remark 9.33. This lemma is a weak form of a more general recent result by J. Mackay and A. Sisto [MS20, Theorem 1.2], who proved Part 2 without assuming that $f^{\ell}$ is a qi embedding (in fact, they also relax the condition (c) in the definition of a relative qi embedding). Part 3 of the lemma then implies that $f^{\ell}$ is a uniform qi embedding provided that $f$ is. See also the recent paper $[\mathbf{H H 2 0}]$ by Healy and Hruska with a similar result for relatively hyperbolic groups.
9.2.3. CT maps. Suppose that $(X, \mathcal{F})$ and $(Y, \mathcal{H})$ are relatively hyperbolic spaces and $f:(Y, \mathcal{H}) \rightarrow(X, \mathcal{F})$ is a morphism of pairs. We then have the hyperbolic extension of $f$, which is a coarse Lipschitz uniformly proper map $f^{h}: Y^{h} \rightarrow X^{h}$ (see Lemma 9.32), as well as the coned-off map $f^{\ell}: Y^{\ell} \rightarrow X^{\ell}$.

Proposition 9.34. The map $f^{h}$ admits a CT-extension provided that the following holds:

For some (equivalently, every) $y_{0} \in Y$, every $K \geq 1$, there is a function $C=C\left(y_{0}, K, D\right)$ such that: For all pairs of points $y_{1}, y_{2} \in Y$, all tight $K$-quasigeodesic $\beta^{\ell}$ in $Y^{\ell}$ connecting $y_{1}, y_{2}$, and all tight $K$-quasigeodesics $\alpha^{\ell}$ in $X^{\ell}$ connecting $x_{1}=f\left(y_{1}\right), x_{2}=f\left(y_{2}\right)$,

$$
d_{X}\left(f\left(y_{0}\right), \alpha^{\ell} \cap X\right) \leq D \Rightarrow d_{Y}\left(y_{0}, \beta^{\ell} \cap Y\right) \leq C
$$

Proof. Note that, in view of Corollary 9.18, the implication in the proposition can be rewritten as

$$
d_{X}\left(f\left(y_{0}\right),\left[x_{1} x_{2}\right]_{X^{h}} \cap X\right) \leq D \Rightarrow d_{Y}\left(y_{0},\left[y_{1} y_{2}\right]_{Y^{h}} \cap Y\right) \leq C:=\phi(D)
$$

for some function $\phi$. We will be verifying that $f^{h}$ satisfies Mitra's Criterion, Theorem 8.2. Suppose that $y_{1}, y_{2} \in Y^{h}$ are such that

$$
d_{X^{h}}\left(x_{0},\left[x_{1} x_{2}\right]_{X^{n}}\right) \leq D,
$$

where $f\left(y_{i}\right)=x_{i}, i=0,1,2$. Our goal is to get a uniform bound on the distance from $y_{0}$ to $\left[y_{1} y_{2}\right]_{Y^{n}}$ in $Y^{h}$.

Case 1. We first suppose that $y_{1}, y_{2}$ are both in $Y$. Then, $x_{1}, x_{2}$ are both in $X$ as well. Since $X$ is uniformly properly embedded in $X^{h}$ and $x_{0}$ is in $X$, it follows that there is $x^{\prime} \in\left[x_{1} x_{2}\right]_{X^{h}} \cap X$ within distance $D^{\prime}$ from $x_{0}$, with respect to the metric of $X$, where $D^{\prime}$ depends only on $D$ (and geometry of $(X, \mathcal{H})$, of course), cf. Lemma 1.70. Thus, the assumptions of the proposition imply that

$$
d_{Y}\left(y_{0},\left[y_{1} y_{2}\right]_{Y^{h}} \cap Y\right) \leq C^{\prime},
$$

where $C^{\prime}$ is a function of $D$. This, of course, implies that

$$
d_{Y^{n}}\left(y_{0},\left[y_{1} y_{2}\right]_{Y^{n}}\right) \leq C^{\prime}
$$

as required by Mitra's Criterion.
Case 2. Suppose that both $y_{1}, y_{2}$ belong to the same $H_{i}^{h}$. In view of Lemma 1.70, we obtain that for $k=1$ or $k=2, d\left(x_{0}, x_{k}\right) \leq D^{\prime}$, for some $D^{\prime}$ depending only on $D$. Uniform properness of $f^{h}$ then implies that $d_{Y^{h}}\left(y_{0}, y_{k}\right)$ is also uniformly bounded, as required.

Case 3. Suppose that $y_{1} \in H_{i_{1}}^{h}, y_{2} \in H_{i_{2}}^{h}$ and $H_{i_{1}}^{h} \neq H_{i_{2}}^{h}$. Thus, $x_{i} \in F_{j_{i}}^{h}, F_{j_{i}} \in \mathcal{F}$, are distinct, $i=1,2$. Our assumption that

$$
d_{X^{h}}\left(x_{0},\left[x_{1} x_{2}\right]_{X^{h}}\right) \leq D
$$

implies that there is a point $p \in x_{1} x_{2}=\left[x_{1} x_{2}\right]_{X^{h}} \cap X$ within distance $\leq D^{\prime}=D^{\prime}(D)$ from $\left[x_{1} x_{2}\right]_{X^{h}}$ (cf. the proof in Case 2). Let $x_{i}^{\prime} \in F_{j_{i}}, i=1,2$, be points realizing the minimal distance in $X^{h}$ between $F_{i_{1}}, F_{i_{2}}$. Thus, the $R$-neighborhood of the segment $x_{1} x_{2}$ in $X^{h}$ contains $x_{1}^{\prime} x_{2}^{\prime}$, where $R$ is a uniform constant, see Lemma 1.144. Let $x_{i}^{\prime \prime} \in x_{1} x_{2}$ be points within distance $R$ from $x_{i}^{\prime}, i=1,2$. By the uniform quasiconvexity of $H_{i_{k}}^{h}$ in $X^{h}$, $k=1,2$, if $p$ is not in $x_{1}^{\prime \prime} x_{2}^{\prime \prime}=\left[x_{1}^{\prime \prime} x_{2}^{\prime \prime}\right]_{X^{h}}$ then its distance to $x_{1}^{\prime \prime}$ or $x_{2}^{\prime \prime}$ is uniformly bounded (cf. Corollary 9.4). Thus, it suffices to consider the case when $p \in x_{1}^{\prime \prime} x_{2}^{\prime \prime}$.

Let $w_{i}, i=1,2$, be intersection points of $\left[y_{1} y_{2}\right]_{Y^{h}}=y_{1} y_{2}$ with $H_{i_{1}}^{h}, H_{i_{2}}^{h}$ respectively, and $z_{i}:=f\left(w_{i}\right), t=1,2$. The points $z_{1}, z_{2}$ belong to the peripheral subsets $F_{j_{1}}, F_{j_{2}}$ respectively. Thus, again, the $R$-neighborhood of the segment $z_{1} z_{2}$ contains $x_{1}^{\prime} x_{2}^{\prime}$. Since we are assuming that $p \in x_{1}^{\prime \prime} x_{2}^{\prime \prime}$, it follows that

$$
p \in N_{2 R+\delta}\left(z_{1} z_{2}\right)
$$

with respect to the metric of $X^{h}$. Hence, $d_{X^{h}}\left(x_{0},\left[z_{1} z_{2}\right]_{X^{h}}\right) \leq 2 R+\delta+D^{\prime}$. Now, we are in the setting of Case 1 and it follows that

$$
d_{Y}\left(y_{0},\left[w_{1} w_{2}\right]_{Y^{h}}\right) \leq \phi\left(2 R+\delta+D^{\prime}\right)
$$

Therefore,

$$
d_{Y^{h}}\left(y_{0},\left[y_{1} y_{2}\right]_{Y^{h}}\right) \leq d_{Y}\left(y_{0},\left[w_{1} w_{2}\right]_{Y^{h}}\right) \leq \phi\left(2 R+\delta+D^{\prime}\right),
$$

as required.
Case 4. Suppose that $y_{1} \notin Y$ and $y_{2} \in Y$. This case is similar to Case 3 and we leave it to the reader.

### 9.3. Trees of relatively hyperbolic spaces

We can now describe axioms of trees of relatively hyperbolic spaces following [MP11]:
Definition 9.35. A tree of relatively hyperbolic spaces is an (abstract) tree of spaces $\mathfrak{X}=(\pi: X \rightarrow T)$ where all vertex and edge spaces have structures of uniformly ${ }^{3}$ relatively hyperbolic spaces $\left(X_{v}, \mathcal{H}_{v}\right),\left(X_{e}, \mathcal{H}_{e}\right)$, and the incidence maps $f_{e v}: X_{e} \rightarrow X_{v}$ are uniform relative qi embeddings. ${ }^{4}$

Remark 9.36. The definition of a tree of relatively hyperbolic spaces given in [MR08] also requires the coned-off maps $f_{e v}^{\ell}: X_{e}^{\ell} \rightarrow X_{v}^{\ell}$ to be uniform qi embeddings. In view of [MS20], this is a consequence of the assumption that the incidence maps are uniform relative qi embeddings (cf. Remark 9.33). The reader not willing to rely upon the results of [MS20], can simply assume that the maps $f_{e v}^{\ell}$ are uniform qi embeddings.

Next, given such a tree of spaces $\mathfrak{X}=(\pi: X \rightarrow T)$, we define an equivalence relation on $X$ generated by the following:

1. For each edge $e=\left[v_{1}, v_{2}\right]$ of $T$, every point in a peripheral subspace $H_{e} \subset X_{e}$ is equivalent to all the points of the mapping cylinders of the incidence maps $f_{\text {vi }_{i}}: H_{e} \rightarrow$ $H_{v} \subset X_{v_{i}}, i=1,2$, in $X$.
2. All points of each peripheral subspace $H_{v} \subset X_{v}, v \in V(T)$, belong to the same equivalence class.

Each equivalence class of this equivalence relation is called a peripheral subspace $P$ of $X$. Observe that for each peripheral subspace $P$ of $X$ and each vertex (resp. edge) space $X_{v}$ (resp. $X_{e}$ ) of $\mathfrak{X}$, the intersection $P \cap X_{v}$ (resp, $P \cap X_{e}$ ) is either empty or equals one of the

[^19]peripheral subspaces of $X_{v}$ (resp. $X_{e}$ ). Given these peripheral subspaces, one defines the new space $X^{P}=\mathcal{G}(X, \mathcal{P})$, by attaching hyperbolic horoballs $P_{j}^{h}$ to $X$ along all peripheral subspaces $P_{j}, j \in J$, of $X$. Here and in what follows, $\mathcal{P}=\left\{P_{j}: j \in J\right\}$.

Remark 9.37. The definition of $X^{P}$ should not be confused with the one, $X^{h}$, of the total space of a tree of spaces over $T$, with the vertex/edge spaces $X_{v}^{h}, X_{e}^{h}$.

Similarly, for each subtree $S \subset T$, we define the space $X_{S}^{P}$ obtained by first restricting the tree of spaces $\mathfrak{X}$ to $S$ and, thus, obtaining a tree of spaces $X_{S} \rightarrow S$, and then applying the above procedure, so that $X_{S}^{P}=\left(X_{S}\right)^{P}$. The peripheral structure of $X_{S}$ is denoted $\mathcal{P}_{S}$.

Additionally, we have the space $\widehat{X}=\mathcal{E}(X, \mathcal{P})$ obtained by coning-off the peripheral subspaces $P \in \mathcal{P}$ in $X$.

Furthermore, we define the tree of coned-off-spaces $\mathfrak{X}^{\ell}=\left(\pi: X^{\ell} \rightarrow T\right)$ with vertex/edge spaces $X_{v}^{\ell}, X_{e}^{\ell}$ and coned-off incidence maps $f_{e v}^{\ell}: X_{e}^{\ell} \rightarrow X_{v}^{\ell}$, which are uniform qi embeddings (see Remark 9.36).

Remark 9.38. In the terminology of [MR08], $X^{\ell}$ is a partially electrocuted space.
The total space $X^{\ell}$ of $\mathfrak{X}^{\ell}$ contains a forest $\mathcal{F}$ which is a collection of pairwise disjoint trees $F_{P}$ corresponding to the peripheral subspaces $P \in \mathcal{P}$ :
(i) The vertices $v_{i v}$ of $F_{P}$ are the apexes $a\left(H_{i v}^{\ell}\right)$ of the cones over the peripheral subspaces $H_{i v}=P \cap X_{v}$ of the vertex-spaces $X_{v}, v \in V(T)$.
(ii) Similarly, the edges $\epsilon_{i e}$ of $F_{P}$ are labeled by the apexes $a\left(H_{i e}^{\ell}\right)$ of the cones over the peripheral subspaces of the edge-spaces $X_{e}, e \in E(T)$, where $H_{i e}=P \cap X_{e}$.
(iii) A vertex $v_{i v}$ (corresponding to $a\left(H_{i v}^{\ell}\right)$ ) of the tree $F_{P}$ is incident to the edge $\epsilon_{i e}$ (corresponding to $a\left(H_{i e}^{\ell}\right)$ ) if and only if the incidence map $f_{e v}$ of $\mathfrak{X}$ sends $H_{i e}$ to $H_{i v}$.

The fact that each graph $F_{P}$ is a tree is a consequence of the following lemma:
Lemma 9.39. Under the projection $X^{\ell} \rightarrow T$, each $F_{P}$ maps isomorphically to a subtree in $T$.

Proof. Connectivity of $F_{P}$ is clear, we need to verify the injectivity of the map. The problem is local and reduces to analyzing vertex-spaces of $\mathfrak{X}$. The only way the map can fail to be injective is if there is an edge $e=[v, w]$ of $T$ and two distinct peripheral subspaces $H_{e i}, H_{e j}$ of $X_{e}$ which map to the same peripheral subspace $H_{v k}$ of $X_{v}$. But this contradicts the condition that $\left(X_{e}, \mathcal{H}_{e}\right) \rightarrow\left(X_{v}, \mathcal{H}_{v}\right)$ is a morphism of relatively hyperbolic spaces.

In particular, the trees $F_{P}$ are uniformly qi embedded in $X^{\ell}$.
Remark 9.40. There are natural projections $\theta_{P}: P \rightarrow F_{P}$ sending each nonempty intersection $P \cap X_{v}=H_{i v}$ to the corresponding vertex $v_{i v}$ of $F_{P}$ and, for $H_{i e}=P \cap X_{e}, e=$ [ $v, w]$, sending the (double) mapping cylinder of $\left.\left(f_{e v} \cup f_{e w}\right)\right|_{H_{i e}}$ to the edge $\epsilon_{i e}$ in such a way that each interval $\{x\} \times[v, w], x \in X_{e}$ maps linearly onto the edge $\epsilon_{i e}$. The mapping cylinder of $\theta_{P}$ is then homeomorphic to the closure in $X^{\ell}$ of the component of $X^{\ell} \backslash X$ containing $F_{P}$. We, therefore, will use the notation $\operatorname{Cyl}\left(F_{P}, P\right)$ for this closure. This viewpoint of identifying $X^{\ell}$ with the space obtained from $X$ by attaching mapping cylinders of peripheral subsets $P \in \mathcal{P}$ to trees, is adapted from [MR08] and [MP11]. In line with the notion of radial segments in cones, we will refer to the projections of intervals $\{x\} \times[0,1] \subset P \times[0,1]$ to $C y l\left(F_{P}, P\right)$ as radial segments in $C y l\left(F_{P}, P\right)$.

The spaces $X^{\ell}$ and $\widehat{X}$ are related by a quotient map $\tau: X^{\ell} \rightarrow \widehat{X}$ which collapses each tree $F_{P} \in \mathcal{F}$ to a single point, the apex $a\left(P^{\ell}\right) \in \widehat{X}$ of the cone over the peripheral subspace $P$. See also the diagram in Section 9.3.1.

We next describe a relative flaring condition for trees of relatively hyperbolic spaces. This condition consists of two parts.

Part 1. The first part of the relative flaring condition requires that the tree of hyperbolic spaces $\mathfrak{X}^{\ell}$ satisfies one of the equivalent flaring conditions, equivalently, the space $X^{\ell}$ is hyperbolic (see Section 2.5 for the detailed discussion).

Part 2. The ( $\lambda, D$ )-flaring:
Let $\Pi=\left(\gamma_{0}, \gamma_{1}\right)$ be a pair of 1 -sections ${ }^{5}$ of $\mathfrak{X}^{\ell}$ over an interval $\llbracket u, w \rrbracket$ of length $\geq D$ in $T$, such that for each vertex $v \in V(\llbracket u, w \rrbracket), \gamma_{i}(v) \in a\left(X_{v}^{\ell}\right), i=0,1$. Then

$$
\Pi_{\max } \geq \lambda \Pi_{0}
$$

where the distances are computed in electrified vertex-spaces.
Mj and Reeves in [MR08] prove the following relative form of the Bestvina-Feighn combination theorem:

Theorem 9.41. For every $\lambda>1, D \geq 2$, if $\mathfrak{X}$ is a tree of relatively hyperbolic spaces satisfying the relative $(\lambda, D)$-flaring condition (both parts), the space $X^{P}$ is hyperbolic.

We refer the reader to the papers by Sisto [Sis13], Gautero [Gau16] and Dahmani [Dah03] for related results.

Lemma 9.42. Assuming that $\mathfrak{X}$ is a tree of relatively hyperbolic spaces satisfying the relative flaring condition, the pair $\left(X^{\ell}, \mathcal{F}\right)$ is a relatively hyperbolic space.

Proof. We will be using Theorem 9.23. Part 1 of the relative flaring condition (together with Theorem 2.58) implies that $X^{\ell}$ is hyperbolic. In view of Lemma 9.39, the peripheral subspaces $F_{P} \in \mathcal{F}$ are trees uniformly qi embedded in $X^{\ell}$. Lastly, Part 2 of the relative flaring condition implies that distinct peripheral subspaces in $\mathcal{F}$ are uniformly pairwise cobounded.

Since the pair $\left(X^{\ell}, \mathcal{F}\right)$ is relatively hyperbolic, we may perform the secondary cone-off construction, coning-off the peripheral subspaces $F_{P} \in \mathcal{F}$ of $X^{\ell}$. The result is a hyperbolic metric space $\widetilde{X}:=\mathcal{E}\left(X^{\ell}, \mathcal{F}\right)$. There is a natural map

$$
\theta: \widehat{X}=\mathcal{E}(X, \mathcal{P}) \rightarrow \widetilde{X}=\mathcal{E}\left(X^{\ell}, \mathcal{F}\right)
$$

which is the identity on $X$ and sends the cone over each $P \in \mathcal{P}$ to the union of $C y l\left(F_{P}, P\right)$ and $C\left(a_{F}, F\right)$ (cone over $F=F_{P}$ ) so that each radial line segment connecting the apex $a=a\left(P^{\ell}\right)$ of $P^{\ell}=C(a, P)$ to a point $x \in P$, maps homeomorphically to the concatenation of the radial line segment in $C(a, F)$ connecting $a$ to a point $y \in F$ with the line radial segment in $C(F, P)$ connecting $y$ to $x$. The next lemma is immediate from the fact that each cone $P^{\ell}$ has unit diameter and for each $F \in \mathcal{F}$, the union of $C y l\left(F_{P}, P\right)$ with the cone $C\left(a_{F}, F\right)$ has diameter 2:

Lemma 9.43. The map $\theta$ is a quasiisometry.
In the follow-up (to [MR08]) paper [MP11], Mj and Pal prove the following result regarding existence of CT maps:

Theorem 9.44. For each vertex $v \in V(T)$, the inclusion map $X_{v}^{h} \rightarrow X^{P}$ admits a CT extension.

[^20]The main result of this chapter is to generalize this theorem to subtrees $S \subset T$ :
Theorem 9.45. For each subtree $S \subset T$, the inclusion map $X_{S}^{P} \rightarrow X^{P}$ admits a $C T$ extension.

Note that the main tools in the proof of Theorem 9.44 in [MP11] were:
(a) A construction of derived ladders in the induced tree of coned-off space $X^{\ell} \rightarrow T$ and
(b) a construction of qi sections in $X$ lying inside these ladders.

We include below proofs of these results for the sake of completeness. (We will also need these results in order to prove Theorem 9.45.) However, we provide simplified proofs modulo the corresponding results for trees of hyperbolic metric spaces.
9.3.1. Comparison of quasigeodesics. Let $\mathfrak{X}=(\pi: X \rightarrow T)$ be a tree of relatively hyperbolic spaces. There are several spaces and, accordingly, several types of quasigeodesics associated with $\mathfrak{X}$. In this section we discuss the relation between different types of quasigeodesics. We begin, however, with a diagram describing spaces where these quasigeodesics live in. Recall that the tree of spaces $\mathfrak{X}=(\pi: X \rightarrow T)$ gives rise to two other trees of spaces:

$$
\mathfrak{X}^{h}=\left(\pi: X^{h} \rightarrow T\right) \nsim \mathfrak{X} \leadsto \mathfrak{X}^{\ell}=\left(\pi: X^{\ell} \rightarrow T\right) .
$$

Both $\mathfrak{X}^{h}$ and $\mathfrak{X}^{\ell}$ are trees of hyperbolic spaces (satisfying Axiom H) but only $\mathfrak{X}^{\ell}$ satisfies the flaring condition. The following diagram describes the relation between five different spaces associated with $X$; the arrow $\theta$ is the quasiisometry described in Lemma 9.43 and the map $\tau$ is the collapsing map from Section 9.3:

We will discuss the following classes of quasigeodesics in these spaces:

- Quasigeodesics in $X^{P}=\underline{\mathcal{G}}(X, \mathcal{P})$.
- Tight quasigeodesics in $\widehat{X}=\mathcal{E}(X, \mathcal{P})$.
- Tight quasigeodesics in $X^{\ell}$.
- Tight quasigeodesics in $\widetilde{X}=\widehat{X^{\ell}}=\mathcal{E}\left(X^{\ell}, \mathcal{F}\right)$.

Our goal is to relate these quasigeodesics. We already know that the first two types of quasigeodesics are uniformly Hausdorff-close to each other (when intersected with $X$, where the distance is computed via the metric $d_{X}$ ), see Theorem 9.17 and Corollary 9.18. In this section we prove that the same holds for the remaining types of quasigeodesics under a suitable tightness assumption on the quasigeodesics in $X^{\ell}$ :

Definition 9.46. We say that a a continuous quasigeodesic in $X^{\ell}$ is tight if its intersection with every $\stackrel{\circ}{C}\left(F_{P}, P\right), P \in \mathcal{P}$, is either empty or is a concatenation of two radial geodesics with a geodesic in $F_{P}$.

By analogy with electrification of paths $\beta$ in $X^{P}$ (where the result is a tight path in $\widehat{X}$ ), we define the partial electrification $\beta^{\ell}$ of $\beta$ as follows:

Definition 9.47 (Partial electrification). Suppose that $\beta$ is a path in $X^{P}$ which is tight with respect to $\mathcal{P}$. For each pair of points $x, y$ in $\beta$ which belong to some $P \in \mathcal{P}$ and such that the subpath $\beta(x, y)$ between points $x, y$ is contained in $\stackrel{\circ}{P}^{h}$, except for the points $x, y$, we replace $\beta(x, y)$ with a geodesic in $\stackrel{\circ}{C}\left(F_{P}, P\right)$ connecting $x$ and $y$. The resulting path $\beta^{\ell}$ is the partial electrification of $\beta$.

It follows from the definition that the path $\beta^{\ell}$ is tight in $X^{\ell}$.
Given a tight quasigeodesic $\beta$ in $X^{\ell}$, we can electrify it with respect to the collection of peripheral subsets $\mathcal{F}$ and obtain a tight quasigeodesic $\widetilde{\beta}=\mathcal{E}_{\mathcal{F}}(\beta)$ in $\widetilde{X}$, see Section 9.1.3. Clearly, this defines an injective map $\beta \mapsto \widetilde{\beta}$ from the set of tight quasigeodesics in $X^{\ell}$ to those in $\widetilde{X}$, under which uniform quasigeodesics correspond to uniform quasigeodesics.

We also have the quasiisometry

$$
\theta: \mathcal{E}(X, \mathcal{P})=\widehat{X} \rightarrow \widetilde{X}=\mathcal{E}\left(X^{\ell}, \mathcal{F}\right)
$$

see Lemma 9.43. This map induces a bijection $\Theta$ between the sets of tight quasigeodesics in $\widehat{X}$ and quasigeodesics of the form $\widetilde{\beta}$ in $\widetilde{X}$. Uniform quasigeodesics again correspond to uniform quasigeodesics. Combining the two maps, we obtain a bijection

$$
\Phi: \alpha \mapsto \Theta(\alpha)=\widetilde{\beta} \mapsto \beta
$$

between the sets of tight quasigeodesics in $\mathcal{E}(X, \mathcal{P})$ and those in $X^{\ell}$. Moreover, the paths $\alpha$ and $\beta$ agree in $X$.

We record these observations as in the following lemma:
Lemma 9.48. There exists a bijection $\Phi$ between the sets of tight quasigeodesics in $\mathcal{E}(X, \mathcal{P})$ and those in $X^{\ell}$. Moreover, a tight path in $\mathcal{E}(X, \mathcal{P})$ is a uniform quasigeodesic if and only if the path $\beta=\Phi(\alpha)$ is in $X^{\ell}$.

As an application, we obtain a result which appears as Lemma 1.21 in [MP11]:
Lemma 9.49. Let $x, y$ be in $X$ and let $\alpha$ be a continuous L-quasigeodesic in $X^{P}$ between these points. Then there exists a tight $L_{9.49}(L)$-quasigeodesic $\beta$ in $X^{\ell}$ connecting $x$ and $y$ such that $\alpha \cap X=\beta \cap X$.

Proof. As described in Section 9.1.3, we convert $\alpha$ to a uniform tight quasigeodesic $\widehat{\alpha}$ in $\widehat{X}$, the electrification of $\alpha$. Then applying the map $\Phi$ as above, we obtain $\beta=\Phi(\alpha)$, a tight quasigeodesic in $X^{\ell}$ whose qi constant depends only on that of $\alpha$. By the construction. $\alpha \cap X=\beta \cap X$.

Corollary 9.50. Any two points in $X \subset X^{\ell}$ are connected by a uniform tight quasigeodesic in $X^{\ell}$.

Suppose that $\beta_{1}, \beta_{2}$ are tight $L$-quasigeodesics in $X^{\ell}$ with the same end-points in $X$. Applying the inverse bijection $\Phi^{-1}$ to $\beta_{1}, \beta_{2}$ we obtain tight $L^{\prime}$-quasigeodesics $\alpha_{1}, \alpha_{2}$ in $\widehat{X}$, again connecting the same points in $X$ and such that $\alpha_{i} \cap X=\beta_{i} \cap X, i=1,2$. Since, by Theorem 9.28 the paths $\alpha_{1}, \alpha_{2}$ uniformly track each other in $X$, we obtain:

Corollary 9.51. Any two tight quasigeodesics in $X^{\ell}$ connecting points of $X$ uniformly track each other in $X$.
9.3.2. Ladders in trees of relatively hyperbolic spaces. By Lemma 9.32, we have a tree of hyperbolic spaces $\mathfrak{X}^{h}=\left(\pi^{h}: X^{h} \rightarrow T\right)$ such that edge-spaces are uniformly quasiisometrically embedded in vertex spaces.

Hence, given $x, y \in X_{u} \subset X_{u}^{h}$ we construct a $(K, D, E)$-ladder $\mathcal{L}^{h} \subset \mathfrak{X}^{h}$ of the geodesic segment $L_{u}^{h}=[x y]_{X_{u}^{h}}$, as we have done in Chapter 3. (Note that flaring conditions were not used in this construction.)

For each vertex $v$ (resp. edge $e$ ) in $\pi\left(L^{h}\right) \subset T$ we have the oriented vertical geodesic segment $L_{v}^{h}=\left[x_{v} y_{v}\right]_{X_{v}^{h}}$ (resp. $L_{e}^{h}=\left[x_{e} y_{e}\right]_{X_{e}^{h}}$ ) of the ladder $\mathcal{L}^{h}$. Coning-off the subsegments of $L_{v}$ (resp. $L_{e}$ ) contained in the peripheral horoballs of $X_{v}^{h}$ (resp. $X_{e}^{h}$ ) we obtain a collection of uniform quasigeodesics in the electrified vertex/edge spaces $X_{v}^{\ell}$ (resp. $X_{e}^{\ell}$ ), see Theorem $9.17(2)$. We let $L_{v}^{\ell}$ (resp. $L_{e}^{\ell}$ ) denote the geodesics in $X_{v}^{\ell}$ (resp. $X_{e}^{\ell}$ ) connecting the endpoints of the above quasigeodesics.

Lemma 9.52. The collection of segments $L_{v}^{\ell}$ and $L_{e}^{\ell}$ defines a $(\hat{K}, \hat{D}, \hat{E})$-ladder $\mathcal{L}^{\ell}$ in $\mathfrak{X}^{\ell}$ 。

Proof. The proof is based on Lemma 3.17. The collection of segments $L_{v}^{\ell}$ and $L_{e}^{\ell}$ satisfies the assumptions of Lemma 3.17 because $\mathcal{L}^{h}$ is a ladder and because coning-off of quasigeodesics coarsely commutes with the nearest-point projections, see Lemma 9.22 as well as Remark 3.2(viii).

We let $L^{\ell}, L^{h}$ denote the total spaces of the ladders $\mathcal{L}^{\ell}$ and $\mathcal{L}^{h}$ respectively. We will say that the ladder $\mathcal{L}^{\ell}$ is derived from the ladder $\mathcal{L}^{h}$.

Remark 9.53. The ladder construction given in [MP11] is a bit more complicated.
By the construction, each ladder is a tree of relatively hyperbolic spaces with the total space $L$ and the peripheral structure $\mathcal{P}_{L}$ (given by the pull-back of the peripheral structure $\mathcal{P}$ of $X)$, and the inclusion map $\left(L, \mathcal{P}_{L}\right) \rightarrow(X, \mathcal{P})$ is a morphism of relatively hyperbolic spaces (we will need only that distinct peripheral subsets map to distinct ones).

Corollary 3.13 (the existence of coarse Lipschitz retractions to ladders in hyperbolic trees of spaces), combined with Lemma 9.52 implies:

Corollary 9.54. There is a coarsely Lipschitz retraction $X^{\ell} \rightarrow L^{\ell}$ with Lipschitz constant depending only on the parameters $K, D, E$.

Applying Corollary 9.50, we obtain:
Corollary 9.55. Any two points in $L \subset L^{\ell}$ are connected by a uniform tight quasigeodesic in $L^{\ell}$.

QI sections in ladders. We next discuss the construction in [MP11] of vertical quasigeodesic rays contained in ladders. We assume that

$$
\mathcal{L}^{h}=\mathcal{L}^{h}\left(\left[x_{u} y_{u}\right]_{X_{u}^{h}}\right)
$$

is a $(K, D, E)$-ladder in $\mathfrak{X}^{h}$ and $\mathcal{L}^{\ell}$ is the ladder in $\mathfrak{X}^{\ell}$ derived from it.
Lemma 9.56. Given a vertex $v \in \pi\left(L^{h}\right)$ and a point $z_{v} \in X_{v} \cap L_{v}^{\ell}$, there is a $k$-qi section $\sigma: \llbracket u, v \rrbracket \rightarrow X$ of $\pi: X \rightarrow T$ such that $\sigma(\llbracket u, v \rrbracket) \subset L^{\ell}, \sigma(v)=z_{v}$. Here, $k$ depends only on $K$ and $E$.

Proof. Arguing inductively, it is clear that it suffices to prove the lemma in the case when $u, v$ span an edge $e=[u, v]$ of $T$. We will use the fact that $\mathcal{L}^{\ell}$ is derived from the $K$-ladder $\mathcal{L}^{h}$. Thus, there exists a point $z \in L_{u}^{h}$ within distance $K$ from $z_{v}$ (the distance is
measured in $\left.X_{u v}^{h}\right)$. Since $z_{v}$ is in $X_{v}$, the incidence maps of $\mathfrak{X}$ are morphisms of relatively hyperbolic spaces, there exists a point $z_{u} \in L_{u}^{h} \cap X_{u}$ within uniformly bounded distance from $z_{v}$ and, hence, within uniformly bounded distance from $z$ in $X_{u v}$. Hence, we set $\sigma(u):=z_{u}$.

### 9.4. Cannon-Thurston maps for trees of relatively hyperbolic spaces

Proof of Theorem 9.45: In the proof we shall use the following criterion for the existence of CT maps, which appears as Lemma 1.29 in [MP11]. Recall that we have a subtree $\mathfrak{X}_{S}^{\ell}=\left(X^{\ell} \rightarrow S\right)$ in the tree of hyperbolic spaces $\mathfrak{X}^{\ell}=\left(X^{\ell} \rightarrow T\right)$. We fix a point $x_{0} \in X_{\nu_{0}}$, where $v_{0} \in V(S)$.

Lemma 9.57. A CT map for $X_{S}^{P} \rightarrow X^{P}$ exists provided that the following condition holds:

For each $k \geq 1$ and $M \geq 0$, there is $N \geq 0$ such that for all $x, y \in X_{S}$, if $\gamma^{\ell} \subset$ $X^{\ell}, \gamma_{S}^{\ell} \subset X_{S}^{\ell}$ are tight $k$-quasigeodesics joining $x, y$, then $d_{X}\left(x_{0}, \gamma^{\ell} \cap X\right) \leq M$ implies $d_{X_{S}}\left(x_{0}, \gamma_{S}^{\ell} \cap X_{S}\right) \leq N$.

Proof. Our proof closely follows the one of [MP11, Lemma 1.29]. We will verify that the conditions of Proposition 9.34 are satisfied. The main difference with the setting of the lemma is that Proposition 9.34 was stated in terms of coned-off quasigeodesics $\widehat{\gamma}, \widehat{\gamma}_{S}$ in $\widehat{X}=\mathcal{E}(X, \mathcal{P}), \widehat{X}_{S}=\mathcal{E}\left(X_{S}, \mathcal{P}_{S}\right)$ respectively, connecting $x, y$. Here $\mathcal{P}_{S}$ is the collection of intersections $P \cap X_{S}, P \in \mathcal{P}$.

However, according to Lemma 9.49, the Hausdorff distances (computed in $X$ and $X_{S}$ respectively) between $\gamma^{\ell} \cap X, \widehat{\gamma} \cap X$ and between $\gamma_{S}^{\ell} \cap X_{S}, \widehat{\gamma}_{S} \cap X_{S}$ are uniformly bounded, with bounds depending only on $K$. With this in mind, Proposition 9.34 applies and lemma follows.

We now proceed proving the theorem. Let $x, y \in X_{S}$ be arbitrary points and let $\gamma^{\ell}=$ $[x y]_{X^{\ell}}$ be a uniform tight quasigeodesic in $X^{\ell}$ joining them (see Corollary 9.50). Suppose $z \in \gamma^{\ell} \cap X$ is a point such that $d_{X}\left(x_{0}, z\right) \leq D$ for some $D \geq 0$.

We apply the cut-and-replace operation (see Definition 8.12) to the tree of spaces $\mathfrak{X}^{\ell}$ and the quasigeodesic $\gamma^{\ell}$, transforming it to a path $\widehat{\gamma^{\ell}}$ in $X_{S}^{\ell}$. By Theorem 8.19 , the path $\widehat{\gamma^{\ell}}$ in $X_{S}^{\ell}$ is a uniform quasigeodesic. Tightness of $\gamma^{\ell}$ implies that of $\widehat{\gamma^{\ell}}$.

Case 1. Suppose that $z \in X_{S}$. By the construction of $\widehat{\gamma^{\ell}}$, the point $z$ lies on $\widehat{\gamma^{\ell}}$. By Corollary 9.51 , any two tight uniform quasigeodesics in $X_{S}^{\ell}$ uniformly track each other in $X_{S}$. Hence, each tight uniform quasigeodesic $\gamma_{S}^{\ell}$ in $X_{S}^{\ell}$ (connecting $x$ and $y$ ) passes within uniformly bounded distance (in terms of the metric of $X_{S}$ ) from the point $z$. Thus, the implication required by Proposition 9.57 holds and we are done in this case.

Case 2. Suppose that $z \notin X_{S}$. Then there is a vertex $v \in V(S)$ and a component $\gamma_{1}^{\ell}$ of $\gamma^{\ell} \backslash X_{S}^{\ell}$, such that $z \in \gamma_{1}^{\ell}$ and the end-points $x_{1}, y_{1}$ of $\gamma_{1}^{\ell}$ belong to $X_{v}^{\ell}$.

Subcase 2.1. We first consider the subcase when $x_{1}, y_{1}$ both belong to $X_{v}$. Let $T_{1}$ be the smallest subtree of $T$ such that $\gamma_{1}^{\ell}$ is contained in $X_{T_{1}}^{\ell}$. In other words, $T_{1}$ is the span of a component of $T \backslash S$ and the vertex $v$. In the tree of spaces $\mathfrak{X}_{T_{1}}^{\ell}$ we construct a ladder

$$
\mathcal{L}^{\ell}=\mathcal{L}^{\ell}\left(\left[x_{1} y_{1}\right]_{X_{v}^{\ell}}\right)
$$

with the total space $L^{\ell}$, as described in Section 9.3.2.
Let $\bar{\gamma}_{1}^{\ell}$ be a uniform tight quasigeodesic joining $x_{1}, y_{1}$ in $L^{\ell}$. Since the ladder $L^{\ell}$ is uniformly qi embedded in $X_{T_{1}}^{\ell}$ (see Corollary 3.13), $\bar{\gamma}_{1}^{\ell}$ is also a uniform quasigeodesic in
$X_{T_{1}}^{\ell}$. Moreover, since the inclusion $\mathcal{L}^{\ell} \rightarrow \mathfrak{X}_{T_{1}}^{\ell}$ corresponds to a morphism of relatively hyperbolic spaces

$$
\left(L, \mathcal{P}_{L}\right) \rightarrow\left(X_{T_{1}}, \mathcal{P}_{T_{1}}\right),
$$

the path $\bar{\gamma}_{1}^{\ell}$ is tight in $X_{T_{1}}^{\ell}$.
Applying Corollary 9.51 again, we obtain that $z \in \gamma_{1}^{\ell} \cap X_{T_{1}}$ is $C$-close (in terms of the metric of $X_{T_{1}}$ ) to a point $\bar{z} \in \bar{\gamma}_{1}^{\ell} \cap X_{w}$ for some vertex $w \in V\left(T_{1}\right)$, where $C$ depends only on qi constants of the original quasigeodesic $\gamma_{1}^{\ell}$. Recall that $d_{X}\left(x_{0}, z\right) \leq D$. Then $d_{X}\left(x_{0}, \bar{z}\right) \leq D_{1}:=D+C$.

According to Lemma 9.56, there exists a $k$-qi section $\sigma$ over $\llbracket v, w \rrbracket$ with image in $L^{\ell} \cap X$, such that $\sigma(w)=\bar{z}$ and

$$
\sigma(v)=z_{1} \in\left[x_{1} y_{1}\right]_{X_{v}^{t}} .
$$

Since $z_{1}$ belongs to $X_{S}, d_{T}(v, w) \leq D_{1}$ and $d_{X}\left(x_{0}, \bar{z}\right) \leq D_{1}$, it follows that

$$
d_{X}\left(x_{0}, z_{1}\right) \leq k D_{1}+D_{1}
$$

Thus, we can apply the same reasoning as in the case when $z$ is in $X_{S}$, to conclude that for every uniform tight quasigeodesic $\gamma_{S}^{\ell}$ in $X_{S}^{\ell}$ connecting $x, y$ such that the minimal distance (in $X_{S}$ ) from $\gamma_{S}^{\ell} \cap X_{S}$ to $z$ is uniformly bounded.

Subcase 2.2. Suppose that one of the two points $x_{1}, y_{1}$ is in $X_{v}$ and the other is not. After relabeling, we can assume that $x_{1} \in X_{v}$ and $y_{1} \notin X_{v}$.

The (tight) geodesic $\left[x_{1} y_{1}\right]_{X_{v}^{\ell}}$ contains a maximal subpath $\left[y_{1}^{\prime} y_{1}\right]_{X_{v_{1}}}$ of length $\leq 1$ contained in $X_{v}^{\ell} \backslash X_{v}$. The concatenation $\gamma_{1}^{\prime}$ of this path and $\gamma_{1}^{\ell}$ is still tight, $\gamma_{1}^{\prime}$ is again a uniform quasigeodesic in $\mathfrak{X}_{T_{1}}^{\ell}$, and both of its endpoints are in $X_{v_{1}}$. Now, we repeat the argument in Subcase 2.1 with respect to the pair of points $x_{1}, y_{1}^{\prime} \in X_{v}$ and the uniform tight quasigeodesic $\gamma_{1}^{\prime}$ connecting them.

Subcase 2.3. The subcase when both points $x_{1}, y_{1}$ are not in $X_{v}$ but $\left[x_{1} y_{1}\right]_{X_{v}^{\ell}} \cap X_{v} \neq \emptyset$ is similar to Subcase 2.2 and we leave it to the reader.

Subcase 2.4. $\left[x_{1} y_{1}\right]_{X_{v}^{t}} \cap X_{v}=\emptyset$, which implies that the points $x_{1}, y_{1}$ are within unit distance from each other in $X_{v}^{\ell}$. Tightness of the path $\gamma_{1}^{\ell}$ then implies that $\gamma_{1}^{\ell}$ is disjoint from $X$, which contradicts the assumption that $z \in \gamma_{1}^{\ell} \cap X$.

### 9.5. Cannon-Thurston laminations for trees of relatively hyperbolic spaces

Since the inclusion map $X_{S}^{P} \rightarrow X^{P}$ admits a CT-map, one can also define its CannonThurston lamination. Unlike Chapter 8 (specifically, Sections 8.7, 8.8 and 8.9) where these laminations were discussed in great detail in the absolute case, here we limit our discussion to a (weak) analogue of Theorem 8.50(1), relating these CT-laminations to that of the inclusion maps $X_{v}^{h} \rightarrow X^{P}$ (Theorem 9.58 below).

From now on, we assume, as we did in Theorem 8.50, that $X$ is a proper metric space. Let $S \subset T$ be a subtree. We then have the inclusion map $X_{S}^{P} \rightarrow X^{P}$ that, according to Theorem 9.45, admits a CT-map $\partial_{X_{S}^{P}, X^{P}}$.

Theorem 9.58. Suppose that $\xi^{ \pm}$are distinct points in $\partial_{\infty} X_{S}^{P}$ such that

$$
\eta=\partial_{X_{S}^{P}, X^{P}}\left(\xi^{-}\right)=\partial_{X_{S}^{P}, X^{p}}\left(\xi^{+}\right)
$$

1. Then there exists a vertex-space $X_{v} \subset X_{S}$ and a complete geodesic $\alpha: \mathbb{R} \rightarrow X_{v}^{h}$, asymptotic to $\xi_{ \pm}$in $X_{S}^{P}$ and asymptotic (in $X_{v}^{h}$ ) to points $\xi_{v}^{ \pm} \in \partial_{\infty} X_{v}^{h}$, such that

$$
\partial_{X_{v}^{h}, X^{P}}\left(\xi_{v}^{+}\right)=\partial_{X_{v}^{h}, X^{P}}\left(\xi_{v}^{-}\right)=\eta .
$$

## 2. Moreover, $\alpha$ is a uniform quasigeodesic in $X_{S}^{P}$.

Remark 9.59. In this situation we necessarily have

$$
\partial_{X_{v}^{h}, X_{S}^{p}}\left(\xi_{v}^{ \pm}\right)=\xi_{ \pm} .
$$

Proof. The proof follows the arguments of Proposition 8.47. Our first task is to modify the cut-and-replace procedure (Definition 8.12), used in the proof of Proposition 8.47. As before, we will be identifying spaces $X_{v}^{h}$ with their images in $X^{P}, v \in V(T)$; ditto $X_{S}^{P}$. The modification of a path $\beta$ in $X^{P}$ to a path $\hat{\beta}$ in $X_{S}^{P}$ will be done in two steps.

Step 1. The first step simply repeats what is done in Definition 8.12 (except that $X^{P}$ and $X_{S}^{P}$ are not exactly total spaces of trees of spaces!): We identify primary detour subpaths $\zeta_{v}$ of $\beta$, connecting points $x_{v}, y_{v}$ of vertex-spaces $X_{v}^{h}, v \in V(S)$, and, apart from these end-points, lying outside of $X_{S}^{P}$. We then replace each detour subpath with a geodesic $\left[x_{v} y_{v}\right]_{X_{v}^{h}}$ in $X_{v}^{h}$. These geodesic segments are the primary replacement subpaths for $\beta$. As in Definition 8.12 , we refer to the resulting path as $\beta_{S}$ : Its image entirely lies in $X_{S}^{P}$. The trouble is that, unlike the absolute case, even if $\beta$ is uniformly quasigeodesic, the paths $\beta_{S}$ are priori are not even uniformly proper in $X_{S}^{P}$.

Step 2. We then modify $\beta_{S}$ with respect to the collection of peripheral subsets $\mathcal{P}_{S}$ of $X_{S}$ as follows. We define secondary detour subpaths of $\beta_{S}$ as subpaths $\zeta_{P}$ in $\beta_{S}$ connecting points of peripheral subsets $P \in \mathcal{P}_{S}$ of $X_{S}$ and, besides those points, lying entirely inside the open peripheral horoballs $\stackrel{\circ}{P}^{h} \subset X_{S}^{P}$. The path

$$
\hat{\beta}=\mathcal{G}_{X_{S}, \mathcal{P}_{S}}\left(\beta_{S}\right)
$$

the hyperbolization of $\beta_{S}$, is obtained by replacing each secondary detour subpath $\zeta_{P}$ with a geodesic in $P^{h}$ connecting the end-points of $\zeta_{P}$.

Our next goal is to relate quasigeodesic properties of $\beta$ to that of $\hat{\beta}$. We will be using the notion of tight paths, Definition 9.13. The following lemma is clear:

Lemma 9.60. Suppose that $\beta$ in $X^{P}$ is tight with respect to $\mathcal{P}$.

1. For each subtree $S \subset T$, the cut-and-replace path $\beta_{S}$ is tight with respect to $\mathcal{P}_{S}$, and so is the path $\hat{\beta}$.
2. $\left(\beta_{S}\right)^{\ell}=\left(\beta^{\ell}\right)_{S}$, where $\beta_{S}$ is the result of application Step 1 to $\beta$ as above and $\left(\beta_{S}\right)^{\ell}$ is its partial electrification (a tight path in $X_{S}^{\ell}$, see Definition 9.47), while $\left(\beta^{\ell}\right)_{S}$ is the result of application of the cut-and-replace procedure from Definition 8.12 to the path $\beta^{\ell}$ (the partial electrification of $\beta$ ) in the tree of spaces $\mathfrak{X}^{\ell}=\left(X^{\ell} \rightarrow T\right)$.

In view of Part 2 of this lemma, we will use the notation $\beta_{S}^{\ell}$ for $\left(\beta_{S}\right)^{\ell}=\left(\beta^{\ell}\right)_{S}$.
Recall that the map $\Phi$ defined in Section 9.3.1 establishes a bijection between tight paths in $\mathcal{E}(X, \mathcal{P})$ and those in $X^{\ell}$; same for the corresponding map $\Phi_{S}$ for the electric space $\mathcal{E}\left(X_{S}, \mathcal{P}_{S}\right)$ and $X_{S}^{\ell}$. The following lemma is again a direct consequence of the definitions:

Lemma 9.61. For every path $\beta$ in $X^{P}$, tight with respect to $\mathcal{P}$, the path $\hat{\beta}$ can be described as follows. Set $\hat{\beta}_{S}:=\Phi_{S}^{-1}\left(\beta_{S}^{\ell}\right)$. Then $\hat{\beta}$ equals the path obtained via hyperbolization of $\hat{\beta}_{S}$ with respect to $\mathcal{P}_{S}$, i.e.

$$
\hat{\beta}=\mathcal{G}_{X_{S}, \mathcal{P}_{S}}\left(\hat{\beta}_{S}\right)
$$

This lemma has an important consequence:
Corollary 9.62. If $\beta$ is a tight L-quasigeodesic in $X$, then $\hat{\beta}$ is an $L_{9.62}(L)$ - quasigeodesic in $X_{S}^{P}$.

Proof. First of all, according to Theorem 9.17(2), the path $\beta^{\ell}$ is a uniform (in terms of $L$ ) quasigeodesic in $X^{\ell}$. Thus, by Theorem 8.19, so is the path $\beta_{S}^{\ell}=\left(\beta^{\ell}\right)_{S}$, in $X_{S}^{\ell}$. By Lemma 9.48, the path $\hat{\beta}_{S}$ is also. Lastly, by Lemma 9.15, it follows that the path $\hat{\beta}=\mathcal{G}_{X_{S}, \mathcal{P}_{S}}\left(\hat{\beta}_{S}\right)$ is also a uniform quasigeodesic in $X_{S}^{P}$.

With these preliminaries out of the way, we can now proceed with the proof of Theorem 9.58. Fix a base-point $x_{0} \in X_{S}$. Let ( $x_{n}^{ \pm}$) denote sequences in $X_{S}$ converging in $X_{S}^{P} \cup \partial_{\infty} X_{S}^{P}$ to the points $\xi^{ \pm}$respectively, see Lemma 9.10. We let $\beta_{n}$ denote a sequence of tight (with respect to $\mathcal{P}$ ) uniformly quasigeodesic paths in $X^{P}$ connecting the points $x_{n}^{-}, x_{n}^{+}$. According to Corollary 9.62 , the paths $\hat{\beta}_{n}$ are uniformly quasigeodesic. Thus, since, by the assumption, $\xi^{+} \neq \xi^{-}$, it follows that there is a constant $C$ such that $d\left(x_{0}, \hat{\beta}_{n}\right) \leq C$. We let $z_{n}$ denote a point in $\hat{\beta}_{n}$ within distance $C$ from $x_{0}$. Without loss of generality, we may assume that these points lie in the images in $X_{S}^{P}$ of spaces $X_{v_{n}}^{h}, v_{n} \in S$. Since $X$ is assumed to be proper, so is $X_{S}$. Therefore, after extraction, we may assume that all points $z_{n}$ lie in $X_{v}^{h}$ for some vertex $v \in V(S)$.

Case 1: All points $z_{n}$ lie in $X_{v}$. Since the sequence of distances $d\left(x_{0}, \beta_{n}\right)$ diverges to $\infty$, for all but finitely many $n$ 's, the points $z_{n}$ lie in secondary replacement segments

$$
\left[z_{n}^{+} z_{n}^{-}\right]_{X_{v}}=\hat{\zeta}_{v n} \subset \hat{\beta}_{n} \cap X_{v} .
$$

Recall that, by the construction of $\hat{\beta}_{n}$, for each $n$ we also have a primary replacement segment $\zeta_{v n}=\left[y_{n}^{+} y_{n}^{-}\right]_{X_{v}^{h}}$ of $\beta_{n}$, containing $\left[z_{n}^{+} z_{n}^{-}\right]_{X_{v}}$, where $y_{n}^{ \pm}$lie on $\beta_{n}$. Since $d\left(x_{0}, \beta_{n}\right) \rightarrow \infty$,

$$
\lim _{n \rightarrow \infty} d\left(x_{0}, y_{n}^{ \pm}\right)=\infty .
$$

By the properness of $X_{v}$, since $z_{n}$ is in $\zeta_{v n}$ and $d\left(x_{0}, z_{n}\right) \leq C$, after further extraction, the sequence of geodesics $\left[y_{n}^{+} y_{n}^{-}\right]_{X_{v}^{h}}$ converges to a biinfinite geodesic $\alpha$ in $X_{v}^{h}$ connecting points $\xi_{v}^{ \pm} \in \partial_{\infty} X_{v}^{h}$. Using again the assumption that $d\left(x_{0}, \beta_{n}\right) \rightarrow \infty$, and the points $x_{n}^{ \pm}, y_{n}^{ \pm}$all lie on the uniform quasigeodesic $\beta_{n}$, we see that

$$
\partial_{X_{v}^{h}, X^{P}}\left(\xi_{v}^{+}\right)=\partial_{X_{v}^{h}, X^{P}}\left(\xi_{v}^{-}\right)=\partial_{X_{S}^{P}, X^{P}}\left(\xi^{+}\right)=\partial_{X_{S}^{P}, X^{P}}\left(\xi^{-}\right)
$$

This proves the first claim of the theorem in Case 1.
It remains to show that $\alpha$ (or, for this matter, any uniform quasigeodesic in $X_{v}^{h}$ asymptotic to $\xi_{v}^{ \pm}$) is a uniform quasigeodesic in $X_{S}^{P}$. Note that, since paths $\hat{\beta}_{n}$ are uniform quasigeodesics in $X_{S}^{P}$, the same holds for the subpaths $\left[z_{n}^{-} z_{n}^{+}\right]_{X_{v}} \subset \hat{\beta}_{n}$.

Subcase 1a: $\lim _{n \rightarrow \infty} d\left(x_{0}, z_{n}^{ \pm}\right)=\infty$. Then the sequence of subsegments $\left[z_{n}^{-} z_{n}^{+}\right]_{X_{v}}$ (uniformly quasigeodesic in $X_{S}^{P}$ ) subconverges to a geodesic $\alpha_{v}$ in $X_{v}$ also asymptotic to $\xi_{v}^{ \pm}$; it follows that $\alpha_{v}$ is a uniform quasigeodesic in $X_{S}^{P}$.

Subcase 1b: There exists a constant $D$ such that $\lim _{n \rightarrow \infty} d\left(x_{0}, z_{n}^{+}\right)=\infty$ and $d\left(x_{0}, z_{n}^{-}\right) \leq$ $D$ for all $n$. By properness, after further extraction, we can assume that all points $z_{n}^{-}$lie on a fixed peripheral subset $P_{v} \in \mathcal{P}_{X_{v}}$ of $X_{v}$. We then consider the sequence of segments $\left[y_{n}^{-} z_{n}^{+}\right]_{X_{v}}$ instead of the segments $\left[z_{n}^{-} z_{n}^{+}\right]_{X_{v}}$ used in Case 1.

Each segment $\left[y_{n}^{-} z_{n}^{+}\right]_{X_{v}}$ is a concatenation of a vertical geodesic segment

$$
\left[y_{n}^{-} z_{n}^{-}\right]_{X_{v}} \subset P_{v}^{h}
$$

and the geodesic segment $\left[z_{n}^{-} z_{n}^{+}\right]_{X_{v}}$. Since the path $\beta_{n S}$ is tight (with respect to $\mathcal{P}_{S}$ ), its subsegment $\left[y_{n}^{-} z_{n}^{+}\right]_{X_{v}}$ is also tight in $X_{v}^{h}$ with respect to its peripheral structure $\mathcal{P}_{v}$. In particular, the subsegments $\left[z_{n}^{-} z_{n}^{+}\right]_{X_{v}}$ are all disjoint from the open peripheral horoball $\stackrel{\circ}{P}_{v}^{h}$. In particular, $\left[z_{n}^{-} z_{n}^{+}\right]_{X_{v}}$ is disjoint from the open peripheral horoball $\stackrel{\circ}{P}_{S}^{h} \subset X_{S}^{P}$ containing ${ }_{P}^{\circ} h$.

Using the fact that $\left[z_{n}^{-} z_{n}^{+}\right]_{X_{v}}$ and $\left[y_{n}^{-} z_{n}^{+}\right]_{X_{v}}$ are both uniform quasigeodesic in $X_{S}^{P}$, we apply Lemma 9.7 to conclude that the segments $\left[y_{n}^{-} z_{n}^{+}\right]_{X_{v}}$ are uniformly quasigeodesic in $X_{S}^{P}$ as well. Thus, their limit $\alpha_{v}$, a uniform quasigeodesic in $X_{v}^{h}$ asymptotic to $\xi_{v}^{ \pm}$, is also a uniform quasigeodesic in $X_{S}^{P}$.

Subcase 1c: There exists a constant $D$ such that $d\left(x_{0}, z_{n}^{ \pm}\right) \leq D$ for all $n$. The proof is similar to the subcase 1 b and we give only a sketch. We consider the sequence of geodesic segments $\left[y_{n}^{-} y_{n}^{+}\right]_{X_{v}}$ and break each of these as a concatenation of three geodesic segments, two of which are contained in distinct horoballs $P_{v \pm}^{h}$ and one has uniformly bounded length. We again apply Lemma 9.7 to conclude that the segments $\left[y_{n}^{-} y_{n}^{+}\right]_{X_{v}}$ are uniformly quasigeodesic in $X_{S}^{P}$.

Case 2. We now assume that none of the points $z_{n}$ belongs to $X_{S}$. Then, after further extraction, each $z_{n}$ lies in a peripheral horoball $P^{h}$ for some $P \in \mathcal{P}_{S}$. Hence, $z_{n}$ belongs to a geodesic $\left[p_{n} q_{n}\right]_{P^{h}} \subset \hat{\beta}_{n}$, where $p_{n} \in P_{v_{n}}, q_{n} \in P_{w_{n}} \in \mathcal{P}_{X_{w_{n}}}$ and

$$
P_{v_{n}}=X_{v_{n}} \cap P, \quad P_{w_{n}}=X_{w_{n}} \cap P .
$$

By the description of such geodesics $\left[p_{n} q_{n}\right]_{P^{h}}$, up to a uniformly bounded error, the path $\left[p_{n} q_{n}\right]_{P^{h}}$ is the concatenation of two vertical geodesics segments $\left[p_{n} p_{n}^{\prime}\right]_{X_{n n}^{h}},\left[q_{n} q_{n}^{\prime}\right]_{X_{w_{n}}^{h}}$ and a unit horizontal segment in $P^{h}$ connecting $p_{n}^{\prime}, q_{n}^{\prime}$. Thus, either $d_{X_{s}^{p}}\left(z_{n}, p_{n}\right) \leq C$ or $d_{X_{s}^{p}}\left(z_{n}, q_{n}\right) \leq$ $C$. Accordingly, $d_{X_{S}^{p}}\left(x_{0}, p_{n}\right) \leq 2 C$ or $d_{X_{S}^{p}}\left(x_{0}, q_{n}\right) \leq 2 C$. Since $p_{n}, q_{n}$ are in $X_{S}$, Case 2 is reduced to Case 1.

This concludes the proof of the theorem.

## List of symbols

| $\Delta$ | geodesic triangles in metric spaces |
| :---: | :---: |
| $L, \epsilon$ | coarse Lipschitz constants |
| $D, E, \epsilon, R, r$ | bounds on distances |
| $R, r$ | radii of tubular neighborhoods |
| $\ell(\alpha)$, length $(\alpha)$ | length of a path $\alpha$ |
| $c, \alpha, \beta, \gamma, \phi, \psi$ | a path |
| $\hat{c}=c_{S}$ | path obtained from $c$ via the cut-and-replace procedure, Definition 8.12 |
| $\overleftarrow{¢}$ | reversed path of $c$ |
| $c_{1} \star c_{2}$ | concatenation of paths $c_{1}, c_{2}$ |
| $D_{0}$ | Equation (3.5) |
| $K_{0}$ | Notation 2.6.4 |
| $\kappa, k, K$ | quasiisometry and flow constants |
| Function $K^{\prime}$ | Lemma 3.17 |
| Functions $K^{\vee}$ and $K^{\wedge}$ | Equation (3.11) |
| $\stackrel{\lambda}{\rho, \mu, v}$ | quasiconvexity constant retractions |
| $f, g, h$ | maps |
| $P, P_{X, Y}$ | nearest-point projection |
| $\bar{P}$ | the modified projection to a tripod |
| $\bar{x}$ | nearest-point projection of $x$ |
| $\eta$ | a distortion function |
| $\eta_{0}$ | the distortion function of vertex-spaces in a tree of spaces $X$ |
| $V(T)$ | the vertex set of a tree $T$ |
| $e=[u, v]$ | the edge of $T$ connecting vertices $u, v$ |
| $\dot{e}$ | an edge in a tree minus its vertices |
| $E(T)$ | the edge set of a tree $T$ |
| $\gamma_{x}$ | qi sections over an interval or a subtree, passing through $x$ |
| Hd | Hausdorff distance |

| $\llbracket u, v \rrbracket$ or $u v$ | the geodesic segment (interval) connecting vertices $u, v \in V(T)$ in a tree |
| :---: | :---: |
| $\rrbracket u, v \rrbracket, \rrbracket u, v \llbracket, \llbracket u, v \llbracket$ | open and half-open intervals in $T$ |
| $S(u, r)$ | the sphere of radius $r$ and center $u$ |
| $B(u, r)$ | the closed ball of radius $r$ and center $u$ |
| $N_{R}(A)$ | closed $R$-neighborhood of $A$ |
| $b=\operatorname{center}(\Delta)$ | center of a tripod in a tree |
| $\mathcal{X}:=\coprod_{v \in V(T)} X_{v}$ | union of vertex-spaces of a tree of spaces |
| $\mathcal{F} l_{K}(\cdot), F l_{K}(\cdot), \mathfrak{F} l_{K}(\cdot)$ | flow-space (as a tree of spaces), the total space and the intersection with $\mathcal{X}$ respectively |
| $F l\left(X_{v}\right)$ | ideal boundary flow |
| $\mathfrak{L}, \mathcal{L}_{K, D, E}$ | a ladder, as a tree of spaces and intersection with $\mathcal{X}$ respectively |
| $\mathfrak{H}, \mathcal{A}_{K, C}$ | carpets |
| $\Lambda(f), \Lambda(Y, X)$ | CT-lamination |
| $\partial_{\infty}(Y, X)$ | relative ideal boundary of $Y$ in $X$ |
| $\delta_{0}$ | hyperbolicity constant of vertex spaces (total space and intersection with $\mathcal{X}$ ) |
| $\delta_{0}^{\prime}$ | hyperbolicity constant of spaces $X_{u v},[u, v] \in E(T)$ |
| $\lambda_{0}$ | the quasiconvexity constant of $X_{e u} \subset X_{u}, e=[u, v] \in$ $E(T)$ |
| $\lambda_{0}^{\prime}$ | the quasiconvexity constant for the inclusion maps $X_{u} \rightarrow X_{u v},[u, v] \in E(T)$ |
| $L_{0}$ | the quasiisometry constant for the incidence maps $f_{e u}$ : $X_{e} \rightarrow X_{v}$ |
| $L_{0}^{\prime}$ | the quasiisometry constant for the inclusion maps $X_{v} \rightarrow X_{u v}, e=[u, v] \in E(T)$ |
| $N_{R}^{f i b}$ | closed fiberwise $R$-neighborhood |
| $N_{R}^{e}$ | closed neighborhood in $X_{u v}$, where [ $\left.u, v\right]=e \in E(T)$ |
| $\Pi=\left(\gamma_{0}, \gamma_{1}\right)$ | a pair of $K$-qi sections over the same interval in $T$ |
| $\Pi_{0}$ | the girth of $\Pi$ |
| $\Pi_{\text {max }}$ | the maximal separation of the ends of $\Pi$ |
| $\mathfrak{X}=(\pi: X \rightarrow T)$ | a tree of spaces |
| $X_{S}:=\pi^{-1}(S)$ | the total space of a subtree of spaces over $S \subset T$ |
| $\left(Y^{\ell}, d^{\ell}\right)=\mathcal{E}(Y, \mathcal{H})$ | the electrified space |
| $\left(Y^{h}, d^{h}\right)=\mathcal{G}(Y, \mathcal{H})$ | the horoballification |
| $a\left(Y^{\ell}\right)$ | cone-locus |

[^0]:    ${ }^{1}$ Subsequently, alternative proofs of the group-theoretic version of this theorem were given by Kharlampovich and Myasnikov in [KM98] and Gautero in [Gau03], under certain extra assumptions.

[^1]:    ${ }^{1}$ we will omit the adjective "metrically" in what follows

[^2]:    $2_{\text {i.e. isometric, metrically proper and cobounded }}$

[^3]:    ${ }^{1}$ which means that if $g \in G$ preserves an edge $[v, w]$ of $T$, then it also fixes both $v$ and $w$

[^4]:    ${ }^{2}$ In the literature, acylindricity is sometimes defined by requiring only that $G$-stabilizers of intervals of length $\geq k$ are finite, rather than trivial, subgroups.

[^5]:    ${ }^{3}$ The Lipschitz condition is absent in [Mit98], but it holds in all natural examples. On the other hand, Mitra assumes that each restriction $\left.f_{e}\right|_{X_{e} \times \dot{e}}$ is an isometry onto $\pi^{-1}(\dot{e})$, equipped with its path-metric induced from $X$. We find this assumption unnecessarily restrictive.

[^6]:    ${ }^{4}$ Flaring conditions do not require Axiom $\mathbf{H}$.

[^7]:    ${ }^{5}$ For further computations, we find it notationally convenient to write elements of $t^{i} H$ as $h_{i} t^{i}, h_{i} \in H$, which is possible since $H$ is normal in $G$.

[^8]:    ${ }^{1}$ Here maximal means we can not find a $K$-qi section $\Sigma_{x}^{\prime}$ over a subtree $T_{x}^{\prime} \subset T$ containing $T_{x}$ such that $\Sigma_{x} \subsetneq \Sigma_{x}^{\prime}$.

[^9]:    ${ }^{2}$ not necessarily a vertex

[^10]:    ${ }^{3}$ The other two parameters, $D, E$, of $\mathcal{L}$ play no role in this theorem.

[^11]:    ${ }^{1}$ see Definition 3.10

[^12]:    ${ }^{2}$ The parameters $D$ and $E$ of the ladder play no role in the proposition.

[^13]:    ${ }^{1}$ While this $X_{t}$-geodesic is, in general, non-unique, if vertex spaces are uniformly hyperbolic (which will be the case in all our examples) the ambiguity is uniformly bounded and we will ignore it.

[^14]:    ${ }^{2}$ Here and in what follows we repeatedly use the notation $\phi(p, q)$ for a subpath in a path $\phi$ between the points $p, q$ in $\phi$, see Section 1.2.1.

[^15]:    ${ }^{3}$ It is shown in [DKT16, section 7] that in general $\Lambda^{\xi}$ does not depend continuously on $\xi$.

[^16]:    ${ }^{4}$ As it is customary in 3-dimensional topology we will be conflating ends and their neighborhoods.

[^17]:    ${ }^{1}$ This assumption was forgotten in [DM17].

[^18]:    ${ }^{2}$ With respect to the tracking function and the hyperbolicity constant of $Y^{\ell}$.

[^19]:    ${ }^{3}$ I.e. each $X_{v}^{h}, X_{e}^{h}$ is $\delta$-hyperbolic for a uniform constant $\delta$.
    ${ }^{4}$ Recall that this condition also requires the incidence maps to be morphisms of these relatively hyperbolic spaces, $f_{e v}:\left(X_{e}, \mathcal{H}_{e}\right) \rightarrow\left(X_{v}, \mathcal{H}_{v}\right)$.

[^20]:    ${ }^{5}$ For each edge $e_{j}=\left[v_{j}, v_{j+1}\right]$ in $\llbracket u, w \rrbracket, \gamma_{i}\left(e_{j}\right)$ maps to $\gamma_{i}\left(v_{j}\right), \gamma_{i}\left(v_{j+1}\right)$ under the maps $a\left(X_{e_{j}}^{\ell}\right) \rightarrow a\left(X_{v_{j}}^{\ell}\right)$ and $a\left(X_{e_{j}}^{\ell}\right) \rightarrow a\left(X_{v_{j+1}}^{\ell}\right)$.
