Note to the reader. These notes are based to a large extent on Chapters 1–3 in the textbook Probability: Theory and Examples, 4th Ed. by Rick Durrett. References to Durrett’s book appear throughout the text as [Dur2010]. References to the earlier 3rd edition appear as [Dur2004].
1.1 What is probability theory?

In this course we’ll learn about probability theory. But what exactly is probability theory? Like some other mathematical fields (but unlike some others), it has a dual role:

- It is a **rigorous mathematical theory** – with definitions, lemmas, theorems, proofs etc.
- It is a **mathematical model** that purports to explain or model real-life phenomena.

We will concentrate on the rigorous mathematical aspects, but we will try not to forget the connections to the intuitive notion of real-life probability. These connections will enhance our intuition, and they make probability an extremely useful tool in all the sciences. And they make the study of probability much more fun, too! A note of caution is in order, though: mathematical models are only as good as the assumptions they are based on. So probability can be used, and it can be (and quite frequently is) abused...

**Example 1.1.** The **theory of differential equations** is another mathematical theory which has the dual role of a rigorous theory and an applied mathematical model. On the other hand, **number theory**, **complex analysis** and **algebraic topology** are examples of fields which are not normally used to model real-life phenomena.

1.2 The algebra of events

A central notion in probability is that of the **algebra of events** (we’ll clarify later what the word “algebra” means in this context). We begin with an informal discussion. We imagine that probability is a function, denoted \( \mathbf{P} \), that takes as its argument an “event” (i.e., occurrence of something in a real-life situation involving uncertainty) and returns a real number in \([0, 1]\) representing how likely this event is to occur. For example, if a fair coin
is tossed 10 times and we denote the results of the tosses by $X_1, X_2, \ldots, X_{10}$ (where each of $X_i$ is 0 or 1, signifying “tails” or “heads”), then we can write statements like

\[ P(X_i = 0) = 1/2, \quad (1 \leq i \leq 10), \]

\[ P \left( \sum_{i=1}^{10} X_i = 4 \right) = \frac{\binom{10}{4}}{2^{10}}. \]

Note that if $A$ and $B$ represent events (meaning, for the purposes of the present informal discussion, objects that have a well-defined probability), then we expect that the phrases “$A$ did not occur”, “$A$ and $B$ both occurred” and “at least one of $A$ and $B$ occurred” also represent events. We can use notation borrowed from mathematical logic and denote these new events by $\neg A$, $A \lor B$, and $A \land B$, respectively. Thus, the set of events is not just a set – it is a set with some extra structure, namely the ability to perform negation, conjunction and disjunction operations on its elements. Such a set is called an algebra in some contexts.

But what if the coin is tossed an infinite number of times? In other words, we now imagine an infinite sequence $X_1, X_2, X_3, \ldots$ of (independent) coin toss results. We want to be able to ask questions such as

\[ P(\text{infinitely many of the } X_i\text{'s are 0}) = ? \]

\[ P \left( \lim_{n \to \infty} \frac{1}{n} \sum_{k=0}^{n} X_k = \frac{1}{2} \right) = ? \]

\[ P \left( \sum_{k=0}^{\infty} \frac{2X_k - 1}{k} \text{ converges} \right) = ? \]

Do such questions make sense? (And if they do, can you guess what the answers are?) Maybe it is not enough to have an informal discussion to answer this...

**Example 1.2.** (a) An urn initially contains a white ball and a black ball. A ball is drawn out at random from the urn, then added back and another white ball is added to the urn. This procedure is repeated infinitely many times, so that after step $n$ the urn contains 1 black ball and $n+1$ white balls. For each $n \geq 1$, let $A_n$ denote the event that at step $n$ the black ball was drawn. Now let $A_\infty$ denote the event

\[ A_\infty = \text{“in total, the black ball was selected infinitely many times”}, \]
(i.e., the event that infinitely many of the events \(A_n\) occurred).

(b) While this experiment takes place, an identical copy of the experiment is taking place in the next room. The random selections in the two neighboring rooms have no connection to each other, i.e., they are “independent”. For each \(n \geq 1\), let \(B_n\) be the event that at step \(n\) the black ball was drawn out of the “copy” experiment urn. Now let \(B_\infty\) denote the event

\[
B_\infty = \text{“in total, the black ball was selected infinitely many times in the second copy of the experiment”,}
\]

(in other words, the event that infinitely many of the events \(B_n\) occurred).

(c) For each \(n \geq 1\), let \(C_n\) be the event that both \(A_n\) and \(B_n\) occurred, i.e.

\[
C_n = \text{“at step } n\text{, the black ball was selected simultaneously in both experiments”,}
\]

and let \(C_\infty\) denote the event “\(C_n\) occurred for infinitely many values of \(n\)”.

**Theorem 1.3.** We have

\[
P(A_\infty) = P(B_\infty) = 1, \quad P(C_\infty) = 0.
\]

**Proof.** These claims are consequences of the **Borel-Cantelli lemmas** which we will learn about later in the course. Here is a sketch of the proof that \(P(C_\infty) = 0\) (remember, this is still an “informal discussion”, so our “proof” is really more of an exploration of what formal assumptions are needed to make the claim hold). For each \(n\) we have

\[
P(A_n) = P(B_n) = \frac{1}{n + 1},
\]

since at time \(n\) each of the urns contains \(n + 1\) balls, only one of which is black. Moreover, the choices in both rooms are made independently, so we have

\[
P(C_n) = P(A_n \land B_n) = P(A_n)P(B_n) = \frac{1}{(n + 1)^2}.
\]

It turns out that to prove that \(P(C_\infty) = 0\), the only relevant bit of information is that the infinite series \(\sum_{n=1}^{\infty} P(C_n)\) is a convergent series; the precise values of the probabilities are
irrelevant. Indeed, we can try to do various manipulations on the definition of the event \( C \), as follows:

\[
C_\infty = \text{"infinitely many of the } C_n \text{’s occurred"} \\
= \text{"for all } N \geq 1, \text{ the event } C_n \text{ occurred for some } n \geq N".
\]

For any \( N \geq 1 \), denote the event "\( C_n \) occurred for some \( n \geq N \)" by \( D_N \). Then

\[
C_\infty = \text{"for all } N \geq 1, \text{ } D_N \text{ occurred"} \\
= D_1 \land D_2 \land D_3 \land \ldots \text{ (infinite conjunction...?!)} \\
= \bigwedge_{N=1}^{\infty} D_N \text{ (shorthand notation for infinite conjunction).}
\]

In particular, in order for the event \( C_\infty \) to happen, \( D_N \) must happen for any fixed value of \( N \) (for example, \( D_{100} \) must happen, \( D_{101} \) must happen, etc.). It follows that \( C_\infty \) is at most as likely to happen as any of the \( D_N \)’s; in other words we have

\[
P(C) \leq P(D_N), \quad (N \geq 1).
\]

Now, what can we say about \( P(D_N) \)? Looking at the definition of \( D_N \), we see that it too can be written as an infinite disjunction of events, namely

\[
D_N = C_N \lor C_{N+1} \lor C_{N+2} \lor \ldots \text{ (infinite disjunction)} \\
= \bigvee_{n=N}^{\infty} C_n \text{ (shorthand for infinite disjunction).}
\]

If this were a finite disjunction, we could say that the likelihood for at least one of the events to happen is at most the sum of the likelihoods (for example, the probability that it will rain next weekend is at most the probability that it will rain next Saturday, plus the probability that it will rain next Sunday; of course it might rain on both days, so the sum of the probabilities can be strictly greater than the probability of the disjunction). What can we say for an infinite disjunction? Since this is an informal discussion, it is impossible to answer this without being more formal about the precise mathematical model and its assumptions. As it turns out, the correct thing to do (in the sense that it leads to the most interesting and natural mathematical theory) is to assume that this fact that holds for finite
disjunctions also holds for infinite ones. Whether this has any relevance to real life is a different question! If we make this assumption, we get for each \( N \geq 1 \) the bound
\[
P(D_N) \leq \sum_{n=N}^\infty P(C_n).
\]
But now recall that the infinite series of probabilities \( \sum_{n=1}^\infty P(C_n) \) converges. Therefore, for any \( \epsilon > 0 \), we can find an \( N \) for which the tail \( \sum_{n=N}^\infty P(C_n) \) of the series is less than \( \epsilon \). For such an \( N \), we get that \( P(D_N) < \epsilon \), and therefore that \( P(C) < \epsilon \). This is true for any \( \epsilon > 0 \), so it follows that \( P(C) = 0 \). \[\square\]
Chapter 2: Probability spaces

2.1 Basic definitions

We now formalize the concepts introduced in the previous lecture. It turns out that it’s easiest to deal with events as subsets of a large set called the probability space, instead of as abstract logical statements. The logical operations of negation, conjunction and disjunction are replaced by the set-theoretic operations of taking the complement, intersection or union, but the intuitive meaning attached to those operations is the same.

Definition 2.1 (Algebra). If \( \Omega \) is a set, an algebra of subsets of \( \Omega \) is a collection \( \mathcal{F} \) of subsets of \( \Omega \) that satisfies the following axioms:

\[
\emptyset \in \mathcal{F}, \quad (A1)
\]

\[
A \in \mathcal{F} \implies \Omega \setminus A \in \mathcal{F}, \quad (A2)
\]

\[
A, B \in \mathcal{F} \implies A \cup B \in \mathcal{F}. \quad (A3)
\]

A word synonymous with algebra in this context is field.

Definition 2.2 (\( \sigma \)-algebra). A \( \sigma \)-algebra (also called a \( \sigma \)-field) is an algebra \( \mathcal{F} \) that satisfies the additional axiom

\[
A_1, A_2, A_3, \ldots \in \mathcal{F} \implies \bigcup_{n=1}^{\infty} A_n \in \mathcal{F}. \quad (A4)
\]

Example 2.3. If \( \Omega \) is any set, then \( \{\emptyset, \Omega\} \) is a \( \sigma \)-algebra – in fact it is the smallest possible \( \sigma \)-algebra of subsets of \( \Omega \). Similarly, the power set \( \mathcal{P}(\Omega) \) of all subsets of \( \Omega \) is a \( \sigma \)-algebra, and is (obviously) the largest \( \sigma \)-algebra of subsets of \( \Omega \).

Definition 2.4 (Measurable space). A measurable space is a pair \((\Omega, \mathcal{F})\) where \( \Omega \) is a set and \( \mathcal{F} \) is a \( \sigma \)-algebra of subsets of \( \Omega \).

Definition 2.5 (Probability measure). Given a measurable space \((\Omega, \mathcal{F})\), a probability measure on \((\Omega, \mathcal{F})\) is a function \( \mathbf{P} : \mathcal{F} \to [0, 1] \) that satisfies the properties:

\[
\mathbf{P}(\emptyset) = 0, \quad \mathbf{P}(\Omega) = 1, \quad (P1)
\]

\[
A_1, A_2, \ldots \in \mathcal{F} \text{ are pairwise disjoint} \implies \mathbf{P}(\bigcup_{n=1}^{\infty} A_n) = \sum_{n=1}^{\infty} \mathbf{P}(A_n). \quad (P2)
\]
Definition 2.6 (Probability space). A **probability space** is a triple \((\Omega, \mathcal{F}, P)\), where \((\Omega, \mathcal{F})\) is a measurable space, and \(P\) is a probability measure on \((\Omega, \mathcal{F})\).

Intuitively, we think of \(\Omega\) as representing the set of possible outcomes of a probabilistic experiment, and refer to it as the sample space. The \(\sigma\)-algebra \(\mathcal{F}\) is the \(\sigma\)-algebra of events, namely those subsets of \(\Omega\) which have a well-defined probability (as we shall see later, it is not always possible to assign well-defined probabilities to all sets of outcomes). And \(P\) is the “notion” or “measure” of probability on our sample space.

Probability theory can be described loosely as the study of probability spaces (this is of course a gross oversimplification...). A more general mathematical theory called measure theory studies measure spaces, which are like probability spaces except that the measures can take values in \([0, \infty]\) instead of \([0, 1]\), and the total measure of the space is not necessarily equal to 1 (such measures are referred to as \(\sigma\)-additive nonnegative measures). Measure theory is an important and non-trivial theory, and studying it requires a separate concentrated effort. We shall content ourselves with citing and using some of its most basic results. For proofs and more details, refer to Chapter 1 and the measure theory appendix in [Dur2010] or to a measure theory textbook.

2.2 Properties and examples

**Lemma 2.7.** If \((\Omega, \mathcal{F}, P)\) is a probability space, then we have:

(i) **Monotonicity:** If \(A, B \in \mathcal{F}\), \(A \subset B\) then \(P(A) \leq P(B)\).

(ii) **Sub-additivity:** If \(A_1, A_2, \ldots \in \mathcal{F}\) then \(P(\bigcup_{n=1}^{\infty} A_n) \leq \sum_{n=1}^{\infty} P(A_n)\).

(iii) **Continuity from below:** If \(A_1, A_2, \ldots \in \mathcal{F}\) such that \(A_1 \subset A_2 \subset A_3 \subset \ldots\), then

\[
P(\bigcup_{n=1}^{\infty} A_n) = \lim_{n \to \infty} P(A_n).
\]

(iv) **Continuity from above:** If \(A_1, A_2, \ldots \in \mathcal{F}\) such that \(A_1 \supset A_2 \supset A_3 \supset \ldots\), then

\[
P(\bigcap_{n=1}^{\infty} A_n) = \lim_{n \to \infty} P(A_n).
\]
Exercise 2.8. Prove Lemma 2.7.

Example 2.9. Discrete probability spaces. Let Ω be a countable set and let \( p : \Omega \to [0, 1] \) be a function such that
\[
\sum_{\omega \in \Omega} p(\omega) = 1.
\]
This corresponds to the intuitive notion of a probabilistic experiment with a finite or countably infinite number of outcomes, where each individual outcome \( \omega \) has a probability \( p(\omega) \) of occurring. We can put such an “elementary” or “discrete” experiment in our more general framework by defining the \( \sigma \)-algebra of events \( \mathcal{F} \) to be the set of subsets of \( \Omega \), and defining the probability measure \( P \) by
\[
P(A) = \sum_{\omega \in A} p(\omega), \quad A \in \mathcal{F}.
\]
If \( \Omega \) is a finite set, a natural probability measure to consider is the \textbf{uniform measure}, defined by
\[
P(A) = \frac{|A|}{|\Omega|}.
\]

Example 2.10. Choosing a random number uniformly in \((0, 1)\). The archetypical example of a “non-elementary” probability space (i.e., one which does not fall within the scope of the previous example) is the experiment of choosing a random number uniformly in the interval \((0, 1)\). How do we know that it makes sense to speak of such an experiment? We don’t, \textit{yet}. But let us imagine what constructing such an experiment might entail. We are looking for a hypothetical probability space \((\Omega, \mathcal{F}, P)\), in which the sample space \( \Omega \) is simply \((0, 1)\), \( \mathcal{F} \) is some \( \sigma \)-algebra of subsets of \((0, 1)\), and \( P \) is a probability measure that corresponds to our notion of a “uniform” choice of a random number. One plausible way to formalize this is to require that intervals of the form \((a, b) \subset (0, 1)\) be considered as events, and that the probability for our “uniform” number to fall in such an interval should be equal to its length \( b - a \). In other words, we shall require that
\[
(a, b) \in \mathcal{F}, \quad (0 \leq a < b \leq 1),
\]
and that
\[
P((a, b)) = b - a, \quad (0 \leq a < b \leq 1).
\]
How do we generate a $\sigma$-algebra of subsets of $(0,1)$ that contains all the intervals? We already saw that the set of all subsets of $(0,1)$ will work. But that is too large! If we take all subsets, we will see in an exercise later that it will be impossible to construct the probability measure $P$ to satisfy our requirements. So let’s try to build the smallest possible $\sigma$-algebra. One way (which can perhaps be described as the bottom-up approach) would be to start with the intervals, then take all countable unions of such and add them to our collection of sets, then add all countable intersections of such sets, then add all countable unions, etc. Will this work? In principle it can be made to work, but is a bit difficult and requires knowing something about transfinite induction. Fortunately there is a more elegant way (but somewhat more abstract and less intuitive) of constructing the minimal $\sigma$-algebra, that is outlined in the next exercise below, and can be thought of as the top-down approach. The resulting $\sigma$-algebra of subsets of $(0,1)$ is called the Borel $\sigma$-algebra; its elements are called Borel sets.

What about the probability measure $P$? Here we will simply cite a result from measure theory that says that the measure we are looking for exists, and is unique. This is not too difficult to prove, but doing so would take us a bit too far off course.

**Theorem 2.11.** Let $\mathcal{B}$ be the $\sigma$-algebra of Borel sets on $(0,1)$, the minimal $\sigma$-algebra containing all the sub-intervals of $(0,1)$, proved to exist in the exercise below. There exists a unique measure $P$ on the measure space satisfying (1), called Lebesgue measure on $(0,1)$.

**Exercise 2.12** (The $\sigma$-algebra generated by a set of subsets of $\Omega$). (i) Let $\Omega$ be a set, and let $\{\mathcal{F}_i\}_{i \in I}$ be some collection of $\sigma$-algebras of subsets of $\Omega$, indexed by some index set $I$. Prove that the intersection of all the $\mathcal{F}_i$’s (i.e., the collection of subsets of $\Omega$ that are elements of all the $\mathcal{F}_i$’s) is also a $\sigma$-algebra.

(ii) Let $\Omega$ be a set, and let $\mathcal{A}$ be a collection of subsets of $\Omega$. Prove that there exists a unique $\sigma$-algebra $\sigma(\mathcal{A})$ of subsets of $\Omega$ that satisfies the following two properties:

1. $\mathcal{A} \subset \sigma(\mathcal{A})$ (in words, $\sigma(\mathcal{A})$ contains all the elements of $\mathcal{A}$).

2. $\sigma(\mathcal{A})$ is the minimal $\sigma$-algebra satisfying property 1 above, in the sense that if $\mathcal{F}$ is any other $\sigma$-algebra that contains all the elements of $\mathcal{A}$, then $\sigma(\mathcal{A}) \subset \mathcal{F}$. 

Hint for (ii): Let $(F_i)_{i \in I}$ be the collection of all $\sigma$-algebras of subsets of $\Omega$ that contain $A$. This is a non-empty collection, since it contains for example $\mathcal{P}(\Omega)$, the set of all subsets of $\Omega$. Any $\sigma$-algebra $\sigma(A)$ that satisfies the two properties above is necessarily a subset of any of the $F_i$’s, hence it is also contained in the intersection of all the $F_i$’s, which is a $\sigma$-algebra by part (i) of the exercise.

Definition 2.13. If $A$ is a collection of subsets of a set $\Omega$, the $\sigma$-algebra $\sigma(A)$ discussed above is called the $\sigma$-algebra generated by $A$.

Example 2.14. The space of infinite coin toss sequences. Another archetypical experiment in probability theory is that of a sequence of independent fair coin tosses, so let’s try to model this experiment with a suitable probability space. If for convenience we represent the result of each coin as a binary value of 0 or 1, then the sample space $\Omega$ is simply the set of infinite sequences of 0’s and 1’s, namely

$$\Omega = \{(x_1, x_2, x_3, \ldots) : x_i \in \{0, 1\}, i = 1, 2, \ldots \} = \{0, 1\}^\mathbb{N}.$$ 

What about the $\sigma$-algebra $\mathcal{F}$? We will take the same approach as we did in the previous example, which is to require certain natural sets to be events, and to take as our $\sigma$-algebra the $\sigma$-algebra generated by these “elementary” events. In this case, surely, for each $n \geq 1$, we would like the set

$$A_n(1) := \{x = (x_1, x_2, \ldots) \in \Omega : x_n = 1\} \tag{2}$$

to be an event (in words, this represents the event “the coin toss $x_n$ came out Heads”). Therefore we take $\mathcal{F}$ to be the $\sigma$-algebra generated by the collection of sets of this form.

Finally, the probability measure $P$ should conform to our notion of a sequence of independent fair coin tosses. Generalizing the notation in (2), for $a \in \{0, 1\}$ define

$$A_n(a) = \{x = (x_1, x_2, \ldots) \in \Omega : x_n = a\}.$$ 

Then $P$ should satisfy

$$P(A_n(a)) = \frac{1}{2},$$

representing the fact that the $n$-th coin toss is unbiased. But more generally, for any $n \geq 1$ and $(a_1, a_2, \ldots, a_n) \in \{0, 1\}^n$, since the first $n$ coin tosses are independent, $P$ should satisfy

$$P(A_1(a_1) \cap A_2(a_2) \cap \ldots \cap A_n(a_n)) = \frac{1}{2^n}. \tag{3}$$
As in the example of Lebesgue measure discussed above, the fact that a probability measure \( P \) on \( (\Omega, \mathcal{F}) \) that satisfies (3) exists and is unique follows from some slightly non-trivial facts from measure theory, and we will take it on faith for the time being. Below we quote the relevant theorem from measure theory, which generalizes the setting discussed in this example to the more general situation of a \textbf{product} of probability spaces.

\textbf{Theorem 2.15 (Products of probability spaces).} Let \( (\Omega_n, \mathcal{F}_n, P_n)_{n=1}^{\infty} \) be a sequence of probability spaces. Denote \( \Omega = \prod_{n=1}^{\infty} \Omega_n \) (the cartesian product of the outcome sets), and let \( \mathcal{F} \) be the \( \sigma \)-algebra of subsets of \( \Omega \) generated by sets which are of the form

\[
\{(x_1, x_2, \ldots) \in \Omega : x_n \in A\}
\]

for some \( n \geq 1 \) and set \( A \in \mathcal{F}_n \). Then there exists a unique probability measure \( P \) on \( (\Omega, \mathcal{F}) \) such that for any \( n \geq 1 \) and any finite sequence

\[
(A_1, A_2, \ldots, A_n) \in \mathcal{F}_1 \times \mathcal{F}_2 \times \ldots \times \mathcal{F}_n
\]

the equation

\[
P\left(\{(x_1, x_2, \ldots) \in \Omega : x_1 \in A_1, x_2 \in A_2, \ldots, x_n \in A_n\}\right) = \prod_{k=1}^{n} P_k(A_k)
\]

holds.

\textbf{Exercise 2.16.} Explain why the “infinite sequence of coin tosses” experiment is a special case of a product of probability spaces, and why the existence and uniqueness of a probability measure satisfying (3) follows from Theorem 2.15.

In an upcoming homework exercise we will show an alternative way of proving the existence of the probability space of infinite coin toss sequences using Lebesgue measure on \( (0, 1) \).
Chapter 3: Random variables

3.1 Random variables and their distributions

As we have seen, a probability space is an abstract concept that represents our intuitive notion of a probabilistic experiment. Such an experiment however can be very long (even infinite) and contain a lot of information. To make things more manageable, we consider numerical-valued functions on probability spaces, which we call random variables. However, not any function will do: a random variable has to relate in a nice way to the measurable space structure, so that we will be able to ask questions like “what is the probability that this random variable takes a value less than 8”, etc. This leads us to the following definitions.

Definition 3.1. If $(\Omega_1, F_1)$ and $(\Omega_2, F_2)$ are two measurable spaces, a function $X : \Omega_1 \rightarrow \Omega_2$ is called measurable if for any set $E \in F_2$, the set

$$X^{-1}(E) = \{\omega \in \Omega_1 : X(\omega) \in E\}$$

is in $F_1$.

Definition 3.2. If $(\Omega, F, P)$ is a probability space, a real-valued function $X : \Omega \rightarrow \mathbb{R}$ is called a random variable if it is a measurable function when considered as a function from the measurable space $(\Omega, F)$ to the measurable space $(\mathbb{R}, B)$, where $B$ is the Borel $\sigma$-algebra on $\mathbb{R}$, namely the $\sigma$-algebra generated by the intervals.

Exercise 3.3. Let $(\Omega_1, F_1)$ and $(\Omega_2, F_2)$ be two measurable spaces such that $F_2$ is the $\sigma$-algebra generated by a collection $A$ of subsets of $\Omega_2$. Prove that a function $X : \Omega_1 \rightarrow \Omega_2$ is measurable if and only if $X^{-1}(A) \in F_1$ for all $A \in A$.

It follows that the random variables are exactly those real-valued functions on $\Omega$ for which the question

“What is the probability that $a < X < b$?”

has a well-defined answer for all $a < b$. This observation makes it easier in practice to check if a given function is a random variable or not, since working with intervals is much easier than with the rather unwieldy (and mysterious, until you get used to them) Borel sets.
What can we say about the behavior of a random variable $X$ defined on a probability space $(\Omega, \mathcal{F}, P)$? All the information is contained in a new probability measure $\mu_X$ on the measurable space $(\mathbb{R}, \mathcal{B})$ that is induced by $X$, defined by

$$\mu_X(A) = P(X^{-1}(A)) = P(\omega \in \Omega : X(\omega) \in A).$$

The number $\mu_X(A)$ is the probability that $X$ “falls in $A$” (or “takes its value in $A$”).

**Exercise 3.4.** Verify that $\mu_X$ is a probability measure on $(\mathbb{R}, \mathcal{B})$. This measure is called the **distribution** of $X$, or sometimes referred to more fancifully as the **law** of $X$. In some textbooks it is denoted $\mathcal{L}_X$.

**Definition 3.5.** If $X$ and $Y$ are two random variables (possibly defined on different probability spaces), we say that $X$ and $Y$ are **identically distributed** (or **equal in distribution**) if $\mu_X = \mu_Y$ (meaning that $\mu_X(A) = \mu_Y(A)$ for any Borel set $A \subset \mathbb{R}$). We denote this

$$X \overset{d}{=} Y.$$

How can we check if two random variables are identically distributed? Once again, working with Borel sets can be difficult, but since the Borel sets are generated by the intervals, a simpler criterion involving just this generating family of sets exists. The following lemma is a consequence of basic facts in measure theory, which can be found in the Measure Theory appendix in [Dur2010].

**Lemma 3.6.** Two probability measures $\mu_1, \mu_2$ on the measurable space $(\mathbb{R}, \mathcal{B})$ are equal if only if they are equal on the generating set of intervals, namely if

$$\mu_1((a, b)) = \mu_2((a, b))$$

for all $-\infty \leq a < b < \infty$.

### 3.2 Distribution functions

Instead of working with distributions of random variables (which are probability measure on the measurable space $(\mathbb{R}, \mathcal{B})$ and themselves quite unwieldy objects), we will encode them in a simpler object called a **distribution function** (sometimes referred to as a **cumulative distribution function**, or c.d.f.).
**Definition 3.7.** The **cumulative distribution function** (or **c.d.f.**, or just **distribution function**) of a random variable $X$ defined on a probability space $(\Omega, \mathcal{F}, P)$ is the function $F_X : \mathbb{R} \to [0, 1]$ defined by

$$F_X(x) = P(X \leq x) = P(X^{-1}((-\infty, x])) = P(\{\omega \in \Omega : X(\omega) \leq x\}), \quad (x \in \mathbb{R}).$$

Note that we have introduced here a useful notational device that will be used again many times in the following sections: if $A$ is a Borel set, we will often write $\{X \in A\}$ as shorthand for the set $\{\omega \in \Omega : X(\omega) \in A\}$. In words, we may refer to this as “the event that $X$ falls in $A$”. When discussing its probability, we may omit the curly braces and simply write $P(X \in A)$. Of course, one should always remember that on the formal level this is just the set-theoretic inverse image of a set by a function!

**Theorem 3.8** (Properties of distribution functions). If $F = F_X$ is a distribution function, then it has the following properties:

(i) $F$ is nondecreasing.

(ii) $\lim_{x \to \infty} F(x) = 1$, $\lim_{x \to -\infty} F(x) = 0$.

(iii) $F$ is right-continuous, i.e., $F(x+) := \lim_{y \downarrow x} F(y) = F(x)$.

(iv) $F(x-) := \lim_{y \uparrow x} F(y) = P(X < x)$.

(v) $P(X = x) = F(x) - F(x-)$.

(vi) If $G = F_Y$ is another distribution function of a random variable $Y$, then $X$ and $Y$ are equal in distribution if and only if $F \equiv G$.

**Proof.** Exercise (recommended), or see page 9 of [Dur2010].

**Definition 3.9.** A function $F : \mathbb{R} \to [0, 1]$ satisfying properties (i)-(iii) in the previous theorem is called a **cumulative distribution function**, or just **distribution function**.

**Theorem 3.10.** If $F$ is a distribution function, then there exists a random variable $X$ such that $F = F_X$. 

18
This fact has a measure-theoretic proof similar to the proof of Theorem 2.11, but fortunately in this case, there is a more probabilistic proof that relies only on the existence of Lebesgue measure. (This is one of many examples of probabilistic ideas turning out to be useful to prove facts in analysis and measure theory). This involves the probabilistic concept of a quantile, (a generalization of the concepts of percentile and median that we frequently hear about in news reports).

**Definition 3.11.** If \( X \) is a random variable on a probability space \((\Omega, \mathcal{F}, P)\) and \(0 < p < 1\) is a number, then a real number \(x\) is called a \(p\)-quantile of \(X\) if the inequalities

\[
\begin{align*}
P(X \leq x) & \geq p, \\ P(X \geq x) & \geq 1 - p
\end{align*}
\]

hold.

Note that the question of whether \(t\) is a \(p\)-quantile of \(X\) can be answered just by knowing the distribution function \(F_X\) of \(X\): since \(P(X \leq x) = F_X(x)\) and \(P(X \geq x) = 1 - F(x-),\) we can write the conditions above as

\[
F_X(x-) \leq p \leq F_X(x).
\]

**Lemma 3.12.** A \(p\)-quantile for \(X\) always exists. Moreover, the set of \(p\)-quantiles of \(X\) is equal to the (possibly degenerate) closed interval \([a_p, b_p]\), where

\[
\begin{align*}
a_p &= \sup\{x : F_X(x) < p\}, \\ b_p &= \inf\{x : F_X(x) > p\}.
\end{align*}
\]

**Exercise 3.13.** Prove Lemma 3.12.

**Proof of Theorem 3.10.** Let \(((0, 1), \mathcal{B}, P)\) be the unit interval with Lebesgue measure, representing the experiment of drawing a uniform random number in \((0, 1)\). We shall construct our random variable \(X\) on this space. Inspired by the discussion of quantiles above, we define

\[
X(p) = \sup\{y : F(y) < p\}, \quad (0 < p < 1).
\]
If \( F \) were the distribution function of a random variable, then \( X(p) \) would be its (minimal) \( p \)-quantile.

Note that properties (i) and (ii) of \( F \) imply that \( X(p) \) is defined and finite for any \( p \) and that it is a monotone nondecreasing function on \((0, 1)\). In particular, it is measurable, so it is in fact a random variable on the probability space \(( (0, 1), \mathcal{B}, \mathbf{P}) \). We need to show that \( F \) is its distribution function. We will show that for each \( p \in (0, 1) \) and \( x \in \mathbb{R} \), we have that \( X(p) \leq x \) if and only if \( p \leq F(x) \). This will imply that for every \( x \in \mathbb{R} \) we have the equality of sets

\[
\{ p : X(p) \leq x \} = \{ p : p \leq F(x) \},
\]

and, applying \( \mathbf{P} \) to both sides of this equation we will get

\[
F_X(x) = \mathbf{P}(X \leq x) = \mathbf{P}(p : p \leq F(x)) = \mathbf{P}((0, F(x)])) = F(x)
\]

(since \( \mathbf{P} \) is Lebesgue measure).

To prove the claim, note that if \( p \leq F(x) \) then all elements of the set \( \{ y : F(y) < p \} \) satisfy \( y \leq x \), and therefore the supremum \( X(p) \) of this set also satisfies \( X(p) \leq x \). Conversely, if \( p > F(x) \), then, since \( F \) is right-continuous, we have \( p > F(x + \epsilon) \) for some \( \epsilon > 0 \). It follows that \( X(p) \geq x + \epsilon > x \) (since \( x + \epsilon \) is in the set \( \{ y : F(y) < p \} \)).

The function \( X \) defined in the proof above is sometimes referred to as the (lower) quantile function of the distribution \( F \). Note that if \( F \) is a strictly increasing function then \( X \) is simply its ordinary (set-theoretic) inverse function.

### 3.3 Examples

**Example 3.14. Indicator random variables** If \( A \) is an event in a probability space \(( \Omega, \mathcal{F}, \mathbf{P}) \), its **indicator random variable** is the r.v. \( 1_A \) defined by

\[
1_A(\omega) = \begin{cases} 
0 & \omega \notin A, \\
1 & \omega \in A.
\end{cases}
\]

The above discussion shows that to specify the behavior of a random variable, it is enough to specify its distribution function. Another useful concept is that of a **density function**.
If $F = F_X$ is a distribution function such that for some nonnegative function $f : \mathbb{R} \to \mathbb{R}$ we have
\[ F(x) = \int_{-\infty}^{x} f(y) \, dy, \quad (y \in \mathbb{R}), \tag{4} \]
then we say that $X$ has a density function $f$. Note that $f$ determines $F$ but is itself only determined by $F$ up to “small” changes that do not affect the integral in (4) (in measure-theoretic terminology we say that $f$ is determined “up to a set of measure 0”). For example, changing the value $f$ in a finite number of points results in a density function that is equally valid for computing $F$.

**Example 3.15. Uniform random variables.** We say that $X$ is a uniform random variable on $(0, 1)$ if it has the distribution function
\[ F(x) = \begin{cases} 
0 & x \leq 0, \\
x & 0 \leq x \leq 1, \\
1 & x \geq 1.
\end{cases} \]
Such a r.v. has as its density function the function
\[ f(x) = \begin{cases} 
1 & 0 \leq x \leq 1, \\
0 & \text{otherwise}.
\end{cases} \]

More generally, if $a < b$ we say that $X$ is a uniform random variable in the interval $(a, b)$ if it has the (respective) distribution and density functions
\[ F(x) = \begin{cases} 
0 & x \leq a, \\
\frac{x-a}{b-a} & a \leq x \leq b, \\
1 & x \geq b,
\end{cases} \quad f(x) = \begin{cases} 
\frac{1}{b-a} & a \leq x \leq b, \\
0 & \text{otherwise.}
\end{cases} \]

**Example 3.16. Exponential distribution.**
\[ F(x) = \begin{cases} 
0 & x \leq 0, \\
1 - e^{-x} & x \geq 0,
\end{cases} \quad f(x) = \begin{cases} 
0 & x < 0, \\
e^{-x} & x \geq 0.
\end{cases} \]
Example 3.17. Standard normal distribution. The normal (or gaussian) distribution is given in terms of its density function

\[ f(x) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2}. \]

The cumulative distribution function is denoted by

\[ \Phi(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{x} e^{-y^2/2} dy. \]

This integral cannot be evaluated explicitly in terms of more familiar functions, but \( \Phi \) is an important special function of mathematics nonetheless.
Chapter 4: Random vectors and independence

4.1 Random vectors

A random variable is a real-valued measurable function defined on a probability space $(\Omega, \mathcal{F}, P)$ (when we talk of $\mathbb{R}$ as a measurable space, it will always be taken to mean with the $\sigma$-algebra of Borel sets). Similarly, we now wish to talk about vector-valued measurable functions on a probability space, i.e., functions taking values in $\mathbb{R}^d$. First, we need to identify a good $\sigma$-algebra of subsets of $\mathbb{R}^d$. Risking some confusion, we will still call it the Borel $\sigma$-algebra and denote it by $\mathcal{B}$, or sometimes by $\mathcal{B}(\mathbb{R}^d)$.

**Definition 4.1.** The Borel $\sigma$-algebra on $\mathbb{R}^d$ is defined in one of the following equivalent ways:

(i) It is the $\sigma$-algebra generated by boxes of the form

$$(a_1, b_1) \times (a_2, b_2) \times \ldots \times (a_d, b_d).$$

(ii) It is the $\sigma$-algebra generated by the balls in $\mathbb{R}^d$.

(iii) It is the $\sigma$-algebra generated by the open sets in $\mathbb{R}^d$.

(iv) It is the minimal $\sigma$-algebra of subsets of $\mathbb{R}^d$ such that the coordinate functions $\pi_i : \mathbb{R}^d \to \mathbb{R}$ defined by

$$\pi_i(x) = x_i, \quad i = 1, 2, \ldots, d$$

are all measurable (where measurability is respect to the Borel $\sigma$-algebra on the target space $\mathbb{R}$).

**Exercise 4.2.** Check that the definitions above are indeed all equivalent.

**Definition 4.3.** A random (d-dimensional) vector (or vector random variable) $X = (X_1, X_2, \ldots, X_d)$ on a probability space $(\Omega, \mathcal{F}, P)$ is a function $X : \Omega \to \mathbb{R}^d$ that is measurable (as a function between the measurable spaces $(\Omega, \mathcal{F})$ and $(\mathbb{R}^d, \mathcal{B})$).

**Lemma 4.4.** $X = (X_1, \ldots, X_d)$ is a random vector if and only if $X_i$ is a random variable for each $i = 1, \ldots, d$. 

23
Proof. If \( X \) is a random vector then each of its coordinates \( X_i = \pi_i \circ X \) is a composition of two measurable functions and therefore (check!) measurable. Conversely, if \( X_1, \ldots, X_d \) are random variables then for any box \( E = (a_1, b_1) \times (a_2, b_2) \times \cdots \times (a_d, b_d) \subset \mathbb{R}^d \) we have

\[
X^{-1}(E) = \bigcap_{k=1}^d X_i^{-1}((a_i, b_i)) \in \mathcal{F}.
\]

Therefore by Definition 4.1 and Exercise 3.3, \( X \) is a random vector. \( \square \)

Exercise 4.5. (i) Prove that any continuous function \( f : \mathbb{R}^m \to \mathbb{R}^n \) is measurable (when each of the spaces is equipped with the respective Borel \( \sigma \)-algebra).

(ii) Prove that the composition \( g \circ f \) of measurable functions \( f : (\Omega_1, \mathcal{F}_1) \to (\Omega_2, \mathcal{F}_2) \) and \( g : (\Omega_2, \mathcal{F}_2) \to (\Omega_3, \mathcal{F}_3) \) (where \( \Omega_i, \mathcal{F}_i \) are measurable spaces for \( i = 1, 2, 3 \)) is a measurable function.

(iii) Deduce that the sum \( X_1 + \ldots + X_d \) of random variables is a random variable.

Exercise 4.6. Prove that if \( X_1, X_2, \ldots \) is a sequence of random variables (all defined on the same probability space, then the functions

\[
\inf_n X_n, \quad \sup_n X_n, \quad \limsup_n X_n, \quad \liminf_n X_n
\]

are all random variables. Note: Part of the question is to generalize the notion of random variable to a function taking values in \( \mathbb{R} = \mathbb{R} \cup \{-\infty, +\infty\} \), or you can solve it first with the additional assumption that all the \( X_i \)'s are uniformly bounded by some constant \( M \).

4.2 Multi-dimensional distribution functions

If \( X = (X_1, \ldots, X_d) \) is a \( d \)-dimensional random vector, we define its distribution to be the probability measure

\[
\mu_X(A) = \mathbf{P}(X^{-1}(A)) = \mathbf{P}(\omega \in \Omega : X(\omega) \in A), \quad A \in \mathcal{B}(\mathbb{R}^d),
\]

similarly to the one-dimensional case. The measure \( \mu_X \) is also called the joint distribution (or joint law) of the random variables \( X_1, \ldots, X_d \).

Once again, to avoid having to work with measures, we introduce the concept of a \( d \)-dimensional distribution function.
**Definition 4.7.** The $d$-dimensional distribution function of a $d$-dimensional random vector $X = (X_1, \ldots, X_d)$ (also called the joint distribution function of $X_1, \ldots, X_d$) is the function $F_X : \mathbb{R}^d \to [0, 1]$ defined by

$$F_X(x_1, x_2, \ldots, x_d) = \mathbb{P}(X_1 \leq x_1, X_2 \leq x_2, \ldots, X_d \leq x_d)$$

$$= \mu_X\left((-\infty, x_1] \times (-\infty, x_2] \times \ldots \times (-\infty, x_d]\right)$$

**Theorem 4.8** (Properties of distribution functions). If $F = F_X$ is a distribution function of a $d$-dimensional random vector, then it has the following properties:

(i) $F$ is nondecreasing in each coordinate.

(ii) For any $1 \leq i \leq d$, $\lim_{x_i \to -\infty} F(x) = 0$.

(iii) $\lim_{x \to (\infty, \ldots, \infty)} F(x) = 1$.

(iv) $F$ is right-continuous, i.e., $F(x+) := \lim_{y \downarrow x} F(y) = F(x)$, where here $y \downarrow x$ means that $y_i \downarrow x_i$ in each coordinate.

(v) For $1 \leq i \leq d$ and $a < b$, denote by $\Delta_{a,b}^x$ the differencing operator in the variable $x$, which takes a function $f$ of the real variable $x$ (and possibly also dependent on other variables) and returns the value

$$\Delta_{a,b}^x f = f(b) - f(a)$$

Then, for any real numbers $a_1 < b_1, a_2 < b_2, \ldots, a_d < b_d$, we have

$$\Delta_{a_1,b_1}^{x_1} \Delta_{a_2,b_2}^{x_2} \ldots \Delta_{a_d,b_d}^{x_d} F \geq 0.$$

**Proof.** See Chapter 1 in [Dur2010] or Appendix A.2 in [Dur2004].

**Theorem 4.9.** Any function $F$ satisfying the properties in Theorem 4.8 above is a distribution function of some random vector $X$.

**Proof.** See Chapter 1 in [Dur2010] or Appendix A.2 in [Dur2004].
4.3 Independence

Definition 4.10. Events $A, B \in \mathcal{F}$ in a probability space $(\Omega, \mathcal{F}, P)$ are called independent if

$$P(A \cap B) = P(A)P(B).$$

More generally, a family $\mathcal{A} = (A_i)_{i \in I}$ of events in a probability space $(\Omega, \mathcal{F}, P)$ is called an independent family if for any finite subset $A_{i_1}, A_{i_1}, \ldots, A_{i_k} \in \mathcal{A}$ of distinct events in the family we have that

$$P(A_{i_1} \cap A_{i_2} \cap \ldots \cap A_{i_k}) = \prod_{j=1}^{k} P(A_{i_j}).$$

Definition 4.11. Random variables $X, Y$ on a probability space $(\Omega, \mathcal{F}, P)$ are called independent if

$$P(X \in E, Y \in F) = P(X \in E)P(Y \in F)$$

for any Borel sets $E, F \subset \mathbb{R}$. In other words any two events representing possible statements about the behaviors of $X$ and $Y$ are independent events.

Definition 4.12. If $\Omega$ is a set and $X : \Omega \to \mathbb{R}$ is a function, the family of subsets of $\Omega$ defined by

$$\sigma(X) = \left\{ X^{-1}(A) : A \in \mathcal{B}(\mathbb{R}) \right\}$$

is a $\sigma$-algebra (check!) called the $\sigma$-algebra generated by $X$. It is easy to check that it is the minimal $\sigma$-algebra with which $\Omega$ can be equipped so as to make $X$ into a random variable.

Definition 4.13. If $(\Omega, \mathcal{F}, P)$ is a probability space, two $\sigma$-algebras $\mathcal{A}, \mathcal{B} \subset \mathcal{F}$ are called independent if any two events $A \in \mathcal{A}, B \in \mathcal{B}$ are independent events.

It follows from the above definitions that r.v.’s $X, Y$ are independent if and only if the $\sigma$-algebras $\sigma(X), \sigma(Y)$ generated by them are independent $\sigma$-algebras.

Definition 4.14. If $(\Omega, \mathcal{F}, P)$ is a probability space, $\mathcal{F}$ and $(\mathcal{F}_i)_{i \in I}$ is some family of sub-$\sigma$-algebras of $\mathcal{F}$ (i.e., $\sigma$-algebras that are subsets of $\mathcal{F}$, we say that $(\mathcal{F}_i)_{i \in I}$ is an independent family of $\sigma$-algebras if for any $i_1, i_2, \ldots, i_k \in I$ and events $A_1 \in \mathcal{F}_{i_1}, A_2 \in \mathcal{F}_{i_2}, \ldots, A_k \in \mathcal{F}_{i_k}$, the events $A_1, \ldots, A_k$ are independent.
Definition 4.15. A family \((X_i)_{i \in I}\) of random variables defined on some common probability space \((\Omega, \mathcal{F}, P)\) is called an independent family of random variables if the \(\sigma\)-algebras \(\{\sigma(X_i)\}_{i \in I}\) form an independent family of \(\sigma\)-algebras.

Unraveling these somewhat abstract definitions, we see that \((X_i)_{i \in I}\) is an independent family of r.v.’s if and only if we have

\[
P(X_{i_1} \in A_1, \ldots, X_{i_k} \in A_k) = \prod_{j=1}^k P(X_{i_j} \in A_j)
\]

for all indices \(i_1, \ldots, i_k \in I\) and Borel sets \(A_1, \ldots, A_k \in \mathcal{B}(\mathbb{R})\).

Theorem 4.16. If \((\mathcal{F}_i)_{i \in I}\) are a family of sub-\(\sigma\)-algebras of the \(\sigma\)-algebra of events \(\mathcal{F}\) in a probability space, and for each \(i \in I\), the \(\sigma\)-algebra \(\mathcal{F}_i\) is generated by a family \(\mathcal{A}_i\) of subsets of \(\Omega\), and each family \(\mathcal{A}_i\) is closed under taking the intersection of two sets (such a family is called a \(\pi\)-system), then the family \((\mathcal{F}_i)_{i \in I}\) is independent if and only if for each \(i_1, \ldots, i_k \in I\), any finite sequence of events \(A_1 \in \mathcal{A}_{i_1}, A_2 \in \mathcal{A}_{i_2}, \ldots, A_k \in \mathcal{A}_{i_k}\) is independent.

Proof. This uses Dynkin’s \(\pi - \lambda\) theorem from measure theory. See [Dur2010], Theorem 2.1.3, p. 39 or [Dur2004], Theorem (4.2), p. 24. \(\square\)

As a corollary, we get a convenient criterion for checking when the coordinates of a random vector are independent.

Lemma 4.17. If \(X_1, \ldots, X_d\) are random variables defined on a common probability space, then they are independent if and only if for all \(x_1, \ldots, x_d \in \mathbb{R}\) we have that

\[
F_{X_1,\ldots,X_d}(x_1, \ldots, x_d) = F_{X_1}(x_1)F_{X_2}(x_2)\ldots F_{X_d}(x_d).
\]

Exercise 4.18. (i) We say that a Riemann-integrable function \(f : \mathbb{R}^d \to [0, \infty)\) is a (d-dimensional, or joint) density function for a random vector \(X = (X_1, \ldots, X_d)\) if

\[
F_X(x_1, \ldots, x_d) = \int_{-\infty}^{x_1} \int_{-\infty}^{x_2} \ldots \int_{-\infty}^{x_d} f(u_1, \ldots, u_d) \, dx_d \ldots dx_1 \quad \forall x_1, \ldots, x_d \in \mathbb{R}.
\]

Show that if \(f\) is a density for \(X\) and can be written in the form

\[
f(x_1, \ldots, x_d) = f_1(x_1)f_2(x_2)\ldots f_d(x_d),
\]
then $X_1, \ldots, X_d$ are independent.

(ii) Show that if $X_1, \ldots, X_d$ are random variables taking values in a countable set $S$, then in order for $X_1, \ldots, X_d$ to be independent it is enough that for all $x_1, \ldots, x_d \in S$ we have

$$P(X_1 = x_1, \ldots, X_d = x_d) = P(X_1 = x_1) \cdots P(X_d = x_d).$$
Chapter 5: The Borel-Cantelli lemmas

Let \((\Omega, \mathcal{F}, P)\) be a probability space, and let \(A_1, A_2, A_3, \ldots \in \mathcal{F}\) be a sequence of events. We define the following events derived from the sequence \((A_n)_n:\)

\[
\limsup A_n = \bigcap_{N=1}^{\infty} \bigcup_{n=N}^{\infty} A_n, \\
\liminf A_n = \bigcup_{N=1}^{\infty} \bigcap_{n=N}^{\infty} A_n.
\]

What is the meaning of these events? If we think of the sequence \(A_n\) as representing a sequence of (not necessarily independent) probabilistic experiments, then we can translate the first event into words as

\[
\limsup A_n = \text{“the event that for all } N \geq 1 \text{ there is an } n \geq N \text{ such that } A_n \text{ occurred”} \\
= \text{“the event that infinitely many of the } A_n\text{’s occurred”}.
\]

For this reason, the event \(\limsup A_n\) is often denoted by \(\{A_n \text{ infinitely often}\}\) or \(\{A_n \text{ i.o.}\}\).

The definition of the event \(\liminf A_n\) can similarly be given meaning by writing

\[
\liminf A_n = \text{“the event that there exists an } N \geq 1 \text{ such that } A_n \text{ occurred for all } n \geq N” \\
= \text{“the event that all but finitely many of the } A_n\text{’s occurred”}.
\]

Exercise 5.1. Prove that for any \(\omega \in \Omega\) we have

\[
1_{\limsup A_n}(\omega) = \limsup_{n \to \infty} 1_{A_n}(\omega), \\
1_{\liminf A_n}(\omega) = \liminf_{n \to \infty} 1_{A_n}(\omega).
\]

Theorem 5.2 (Borel-Cantelli lemmas).

(i) If \(\sum_{n=1}^{\infty} P(A_n) < \infty\) then \(P(A_n \text{ i.o.}) = 0\).

(ii) If \(\sum_{n=1}^{\infty} P(A_n) = \infty\) and \((A_n)_{n=1}^{\infty}\) are independent then \(P(A_n \text{ i.o.}) = 1\).
Proof. We essentially already proved part (i) in the first lecture, but here is a more general repetition of the same argument.

\[
P(A_n \text{ i.o.) } = P \left( \bigcap_{N=1}^{\infty} \bigcup_{n=N}^{\infty} A_n \right) \leq \inf_{N \geq 1} P \left( \bigcup_{n=N}^{\infty} A_n \right) \leq \inf_{N \geq 1} \sum_{n=N}^{\infty} P(A_n).
\]

Since we assumed that \( \sum_{n=1}^{\infty} P(A_n) \), converges, this last expression is equal to 0.

Proof of (ii): Consider the complementary event that the \( A_n \)'s did not occur for infinitely many values of \( n \). Using De-Morgan’s laws, we get

\[
P(\{A_n \text{ i.o.}\}^c) = P \left( \left( \bigcap_{N=1}^{\infty} \bigcup_{n=N}^{\infty} A_n \right)^c \right) = P \left( \bigcup_{N=1}^{\infty} \bigcap_{n=N}^{\infty} A_n^c \right) \leq \sum_{N=1}^{\infty} P \left( \bigcap_{n=N}^{\infty} A_n^c \right).
\]

So, to show that this is 0 (under the assumptions that \( \sum_{n=1}^{\infty} P(A_n) = \infty \) and that the events are independent), we show that \( P \left( \bigcap_{N=1}^{\infty} A_n^c \right) = 0 \) for all \( N \geq 1 \). Since the events are independent, the probability of the intersection is the product of the probabilities, so we need to show that

\[
\prod_{n=N}^{\infty} (1 - P(A_n)) = 0,
\]

or equivalently (taking minus the logarithm) that

\[
- \sum_{n=N}^{\infty} \log(1 - P(A_n)) = \infty.
\]

But \(- \log(1 - x) \geq x \) for all \( x > 0 \), so this follows from the assumption that the series of probabilities diverges. \(\square\)
Chapter 6: A brief excursion into measure theory

Here we briefly mention some of the basic definitions and results from measure theory, and point out how we used them in the previous lectures. The relevant material is covered in Appendix A.1 in [Dur2010] (Appendix A.1 and A.2 in [Dur2004]). It is not required reading, but if you read it you are perhaps more likely to attain a good understanding of the material that is required...

Definition 6.1. (i) A $\pi$-system is a collection $\mathcal{P}$ of subsets of a set $\Omega$ that is closed under intersection of two sets, i.e., if $A, B \in \mathcal{P}$ then $A \cap B \in \mathcal{P}$.

(ii) A $\lambda$-system is a collection $\mathcal{L}$ of subsets of a set $\Omega$ such that: 1. $\Omega \in \mathcal{L}$; 2. If $A, B \in \mathcal{L}$ and $A \subseteq B$ then $B \setminus A \in \mathcal{L}$; 3. If $(A_n)_{n=1}^\infty$ are all in $\mathcal{L}$ and $A_n \uparrow A$ then $A \in \mathcal{L}$.

The following is a somewhat technical result that turns out to be quite useful:

Theorem 6.2 (Dynkin’s $\pi - \lambda$ theorem). If $\mathcal{P}$ is a $\pi$-system and $\mathcal{L}$ is a $\lambda$-system that contains $\mathcal{P}$ then $\sigma(\mathcal{P}) \subseteq \mathcal{L}$.

Lemma 6.3 (Uniqueness theorem). If the values of two probability measures $\mu_1$ and $\mu_2$ coincide on a collection $\mathcal{P}$ of sets, and $\mathcal{P}$ is a $\pi$-system (closed under finite intersection), then $\mu_1$ and $\mu_2$ coincide on the generated $\sigma$-algebra $\sigma(\mathcal{P})$.

The uniqueness theorem implies for example that to check if random variables $X$ and $Y$ are equal in distribution, it is enough to check that they have the same distribution functions.

Both of the above results are used in the proof of the following important theorem in measure theory:

Theorem 6.4 (Carathéodory’s extension theorem). Let $\mu$ be an almost-probability-measure defined on an algebra $\mathcal{A}$ of subsets of a set $\Omega$. That is, it satisfies all the axioms of a probability measure except it is defined on an algebra and not a $\sigma$-algebra; $\sigma$-additivity is satisfied whenever the countable union of disjoint sets in the algebra is also an element of the algebra. Then $\mu$ has a unique extension to a probability measure on the $\sigma$-algebra $\sigma(\mathcal{A})$ generated by $\mathcal{A}$.

Carathéodory’s extension theorem is the main tool used in measure theory for constructing measures: one always starts out by defining the measure on some relatively small family of
sets and then extending to the generated $\sigma$-algebra (after verifying $\sigma$-additivity, which often requires using topological arguments, e.g., involving compactness). Applications include:

- Existence and uniqueness of Lebesgue measure in $(0, 1), \mathbb{R}$ and $\mathbb{R}^d$.

- Existence and uniqueness of probability measures associated with a given distribution function in $\mathbb{R}$ (sometimes called “Lebesgue-Stieltjes measures in $\mathbb{R}$”). We proved existence instead by starting with Lebesgue measure and using quantile functions.

- Existence and uniqueness of Lebesgue-Stieltjes measures in $\mathbb{R}^d$ (i.e., measures associated with a $d$-dimensional joint distribution function). Here there is no good concept analogous to quantile functions, although there are other ways to construct such measures explicitly using ordinary Lebesgue measures.

- Product measures – this corresponds to probabilistic experiments which consist of several independent smaller experiments.

Note that Durrett’s book also talks about measures that are not probability measures, i.e., the total measure of the space is not 1 and may even be infinite. In this setting, the theorems above can be formulated in greater generality.

End of Part I
Chapter 7: Expected values

7.1 Construction of the expectation operator

We wish to define the notion of the expected value, or expectation, of a random variable \( X \), which will be denoted \( \mathbb{E}X \) (or \( \mathbb{E}(X) \)). In measure theory this is denoted \( \int XdP \) and is called the “Lebesgue integral”. It is one of the most important concepts in all of mathematical analysis! So time invested in understanding it is time well-spent.

The idea is simple. For bounded random variables, we want the expectation to satisfy three properties: First, the expectation of an indicator variable \( 1_A \), where \( A \) is an event, should be equal to \( P(A) \). Second, the expectation operator should be linear i.e., should satisfy \( \mathbb{E}(aX + bY) = a\mathbb{E}X + b\mathbb{E}Y \) for real numbers \( a, b \) and r.v.’s \( X, Y \). Third, it should be monotone, i.e., if \( X \leq Y \) (meaning \( X(\omega) \leq Y(\omega) \) for all \( \omega \in \Omega \)) then \( \mathbb{E}X \leq \mathbb{E}Y \).

For unbounded random variables, we will also require some kind of continuity, but let’s treat the case of bounded case first. It turns out that these properties determine the expectation/Lebesgue integral operator uniquely. Different textbooks may have some variation in how they construct it, but the existence and uniqueness are really the essential facts.

**Theorem 7.1.** Let \((\Omega, \mathcal{F}, P)\) be a probability space. Let \( B_\Omega \) denote the class of bounded random variables. There exists a unique operator \( \mathbb{E} \) that takes a r.v. \( X \in B_\Omega \) and returns a number in \( \mathbb{R} \), and satisfies:

1. If \( A \in \mathcal{F} \) then \( \mathbb{E}(1_A) = P(A) \).
2. If \( X, Y \in B_\Omega, a, b \in \mathbb{R} \) then \( \mathbb{E}(aX + bY) = a\mathbb{E}X + b\mathbb{E}Y \).
3. If \( X, Y \in B_\Omega \) and \( X \geq Y \) then \( \mathbb{E}(X) \geq \mathbb{E}(Y) \).

**Sketch of proof.** Call \( X \) a simple function if it is of the form \( X = \sum_{i=1}^{n} a_i 1_{B_i} \), where \( a_1, \ldots, a_n \in \mathbb{R} \) and \( B_1, \ldots, B_n \) are disjoint events. For such r.v.’s define \( \mathbb{E}(X) = \sum_{i=1}^{n} a_i P(B_i) \). Show that the linearity and monotonicity properties hold, and so far uniqueness clearly holds since we had no choice in how to define \( \mathbb{E}(X) \) for such functions if we wanted the properties
above to hold. Now for a general bounded r.v. $X$ with $|X| \leq M$, for any $\epsilon > 0$ it is possible to approximate $X$ from below and above by simple functions $Y \leq X \leq Z$ such that $E(Z - Y) < \epsilon$. This suggests defining

$$E(X) = \sup\{E(Y) : Y \text{ is a simple function such that } Y \leq X\}.$$  \hspace{1cm} (5)

By approximation, the construction is shown to still satisfy the properties in the Theorem and to be unique, since $E(X)$ is squeezed between $E(Y)$ and $E(Z)$, and these can be made arbitrarily close to each other.

We can now extend the definition of the expectation operator to non-negative random variables. In that case we still define $E(X)$ by eq. (5). This can be thought of as a kind of “continuity from below” axiom that is added to the properties 1–3 above, although we shall see that it can be reformulated in several equivalent ways. Note that now $E(X)$ may sometimes be infinite.

Finally, for a general random variable $X$, we decompose $X$ as a difference of two non-negative r.v.'s by writing

$$X = X_+ - X_-,$$

where $X_+ = \max(X, 0)$ is called the **positive part** of $X$ and $X_- = \max(-X, 0)$ is called the **negative part** of $X$.

We say that $X$ **has an expectation** if the two numbers $E(X_-), E(X_+)$ are not both $\infty$. In this case we define

$$E(X) = E(X_+) - E(X_-).$$

This is a number in $\mathbb{R} \cup \{-\infty, \infty\}$. If both $E(X_-), E(X_+)$ are $< \infty$, or in other words if $E(|X|) < \infty$ (since $|X| = X_+ + X_-)$, we say that $X$ has **finite expectation** or is **integrable**.

**Theorem 7.2.** Suppose $X, Y \geq 0$ or $X, Y \leq 0$ or $E(|X|, E(|Y|) < \infty$. Then:

1. If $X$ is a simple function then the definition (5) coincides with the original definition, namely $E(\sum_i a_i 1_{B_i}) = \sum_i a_i P(B_i)$.

2. $E(aX + bY + c) = aE(X) + bE(Y) + c$ for any real numbers $a, b, c$, where in the case where $E(X) = E(Y) = \pm \infty$, we require $a, b$ to have the same sign in order for the right-hand side of this identity to be well-defined.
3. If $X \geq Y$ then $EX \geq EY$.

Proof. See [Dur2010], section 1.4.

### 7.2 Properties

1. **Expectation is invariant under “almost-sure equivalence”:** If $X \leq Y$ almost surely, meaning $P(X \leq Y) = 1$, then by the definition we have $EX \leq EY$, since any simple function $Z$ such that $Z \leq X$ can be replaced with another simple function $Z'$ such that $Z' \leq Y$ and $Z = Z'$ almost surely. It follows also that if $X = Y$ almost surely then $EX = EY$.

2. **Triangle inequality:** $|EX| \leq E|X|$.

Proof.

$$|EX| = |EX_+ - EX_-| \leq EX_+ + EX_- = E|X|.$$ 

3. **Markov’s inequality** (Called Chebyshev’s inequality in [Dur2010]):

$$P(X \geq t) \leq \frac{EX}{t}.$$ 

Proof. Use monotonicity twice to deduce:

$$P(X \geq t) = E(1_{\{X \geq t\}}) \leq E\left[ \frac{1}{t}X1_{\{X \geq t\}} \right] \leq \frac{EX}{t}.$$
4. Variance: If $X$ has finite expectation, we define its variance to be
$$V(X) = E(X - EX)^2.$$ If $V(X) < \infty$, by expanding the square it is easy to rewrite the variance as
$$V(X) = E(X^2) - (EX)^2.$$ We denote $\sigma(X) = \sqrt{V(X)}$ and call this quantity the standard deviation of $X$. Note that if $a \in \mathbb{R}$ then $V(aX) = a^2V(X)$ and $\sigma(aX) = |a|\sigma(X)$.

5. Chebyshev’s inequality:
$$P(|X - EX| \geq t) \leq \frac{V(X)}{t^2}.$$ \textit{Proof.} Apply Markov’s inequality to $Y = (X - EX)^2$. \hfill \square

6. Cauchy-Schwartz inequality:
$$E|XY| \leq (EX^2EY^2)^{1/2}.$$ Equality holds if and only if $X$ and $Y$ are linearly dependent, i.e. $aX + bY \equiv 0$ holds for some $a, b \in \mathbb{R}$.

\textit{Proof.} Consider the function
$$p(t) = E(|X| + t|Y|)^2 = t^2EY^2 + 2tE|XY| + EX^2.$$ Since $p(t) = at^2 + bt + c$ is a quadratic polynomial in $t$ that satisfies $p(t) \geq 0$ for all $t$, its discriminant $b^2 - 4ac$ must be non-positive. This gives
$$(E|XY|)^2 - EX^2EY^2 \leq 0,$$ as claimed. The condition for equality is left as an exercise. \hfill \square

7. Jensen’s inequality: A function $\varphi : \mathbb{R} \rightarrow \mathbb{R}$ is called convex if it satisfies
$$\varphi(\alpha x + (1 - \alpha)y) \leq \alpha \varphi(x) + (1 - \alpha)\varphi(y)$$ for all $x, y \in \mathbb{R}$ and $\alpha \in [0, 1]$. If $\varphi$ is convex then
$$\varphi(EX) \leq E(\varphi(X)).$$ \textit{Proof.} See homework. \hfill \square
8. $L_p$-norm monotonicity: If $0 < r \leq s$ then

$$\left( \mathbb{E}|X|^r \right)^{1/r} \leq \left( \mathbb{E}|X|^s \right)^{1/s}.$$  \hspace{1em} (6)

**Proof.** Apply Jensen’s inequality to the r.v. $|X|^r$ with the convex function $\varphi(x) = x^{s/r}$. 

7.3 Convergence theorems for expectations

We want to study notions of continuity for the expectation operator. If $X_n \to X$ as $n \to \infty$, under what conditions do we have that $\mathbb{E}(X_n) \to \mathbb{E}X$? First we have to decide what “$X_n \to X$” actually means. We define two notions of convergence of a sequence of random variables to a limit.

**Definition 7.3.** Let $X, X_1, X_2, \ldots$ be random variables all defined on the same probability space. We say that $X_n$ converges in probability to $X$, and denote $X_n \overset{P}{\longrightarrow} X$, if for all $\epsilon > 0$ we have that

$$\mathbb{P}(|X_n - X| > \epsilon) \longrightarrow 0 \quad \text{as} \ n \to \infty.$$ 

**Definition 7.4.** With $X, X_1, X_2, \ldots$ as before, we say that $X_n$ converges almost surely to $X$ (or converges to $X$ with probability 1), and denote $X_n \overset{a.s.}{\longrightarrow} X$, if

$$\mathbb{P}(X_n \to X) = \mathbb{P}\left( \left\{ \omega \in \Omega : X(\omega) = \lim_{n \to \infty} X_n(\omega) \right\} \right) = 1.$$ 

**Exercise 7.5.** Show that $\{ \omega \in \Omega : X(\omega) = \lim_{n \to \infty} X_n(\omega) \}$ is an event and therefore has a well-defined probability. In other words, represent it in terms of countable union, intersection and complementation operations on simple sets that are known to be events. Hint: Use the $\epsilon - \delta$ definition of a limit.

**Lemma 7.6.** Almost sure convergence is a stronger notion of convergence than convergence in probability. In other words, if $X_n \overset{a.s.}{\longrightarrow} X$ then $X_n \overset{P}{\longrightarrow} X$, but the converse is not true.

**Exercise 7.7.** Prove Lemma 7.6. For the counterexample showing that convergence in probability does not imply almost sure convergence, consider the following sequence of random
variables defined on the space \(((0, 1), \mathcal{B}, \text{Lebesgue measure})\):

\[
\begin{align*}
1_{(0,1]}, \\
1_{(0,1/2]}, 1_{(1/2,1]}, \\
1_{(0,1/4]}, 1_{(1/4,2/4]}, 1_{(2/4,3/4]}, 1_{(3/4,1]}, \\
1_{(0,1/8]}, 1_{(1/8,2/8)}, 1_{(2/8,3/8)}, 1_{(3/8,4/8)}, 1_{(4/8,5/8)}, 1_{(5/8,6/8)}, 1_{(6/8,7/8)}, 1_{(7/8,1]}, \\
\ldots
\end{align*}
\]

We can now formulate the fundamental convergence theorems for Lebesgue integration.

**Theorem 7.8** (Bounded convergence theorem). If \(X_n\) is a sequence of r.v.’s such that \(|X_n| \leq M\) for all \(n\), and \(X_n \to X\) in probability, then \(\mathbb{E}X_n \to \mathbb{E}X\).

**Proof.** Fix \(\varepsilon > 0\). Then

\[
\begin{align*}
|\mathbb{E}X_n - \mathbb{E}X| &\leq \mathbb{E}|X_n - X| = \mathbb{E}|X_n - X|1_{\{|X_n - X| > \varepsilon\}} + \mathbb{E}|X_n - X|1_{\{|X_n - X| \leq \varepsilon\}} \\
&\leq 2M\mathbb{P}(|X_n - X| > \varepsilon) + \varepsilon \xrightarrow{n \to \infty} \varepsilon.
\end{align*}
\]

Since \(\varepsilon\) was an arbitrary positive number, this implies that \(|\mathbb{E}X_n - \mathbb{E}X| \to 0\), as claimed. \(\square\)

**Theorem 7.9** (Fatou’s lemma). If \(X_n \geq 0\) then \(\liminf_{n \to \infty} \mathbb{E}X_n \geq \mathbb{E}(\liminf_{n \to \infty} X_n)\).

To see that the inequality in the lemma can fail to be an equality, let \(U \sim U(0, 1)\), and define \(X_n = n1_{\{U \leq 1/n\}}\). Clearly \(\liminf_{n \to \infty} X_n = \lim_{n \to \infty} X_n \equiv 0\), but \(\mathbb{E}(X_n) = 1\) for all \(n\).

**Proof.** Let \(Y = \liminf_{n \to \infty} X_n\). Note that \(Y\) can be written as

\[
Y = \sup_{n \geq 1} \inf_{m \geq n} X_m
\]

(this is a general fact about the lim inf of a sequence of real numbers), or \(Y = \sup_n Y_n\), where we denote

\[
Y_n = \inf_{m \geq n} X_m.
\]

We have \(Y_n \leq X_n\), and as \(n \to \infty\), \(Y_n \to Y\) (in fact \(Y_n \uparrow Y\)) almost surely. Therefore \(\mathbb{E}Y_n \leq \mathbb{E}X_n\), so \(\liminf_{n \to \infty} \mathbb{E}Y_n \leq \liminf_{n \to \infty} \mathbb{E}X_n\), and therefore it is enough to show that

\[
\liminf_{n \to \infty} \mathbb{E}Y_n \geq \mathbb{E}Y.
\]
But for any $M$ we have that
\[ Y_n \wedge M \xrightarrow{a.s.} Y \wedge M, \]
and this is a sequence of uniformly bounded r.v.’s, therefore by the bounded convergence theorem we get that
\[ E(Y_n) \geq E(Y_n \wedge M) \xrightarrow{n \to \infty} E(Y \wedge M). \]
We therefore get that $\lim \inf_{n \to \infty} E(Y_n) \geq E(Y \wedge M)$ for any $M > 0$, which implies the result because of the following exercise.

**Exercise 7.10.** Let $Y \geq 0$ be a random variable. Prove that
\[ E(Y) = \sup_{M > 0} E(Y \wedge M). \]

**Theorem 7.11** (Monotone convergence theorem). If $0 \leq X_n \uparrow X$ as $n \to \infty$ then $E X_n \uparrow EX$.

*Proof.*
\[ EX = E[\lim inf_{n \to \infty} X_n] \leq \lim inf_{n \to \infty} E X_n \leq \lim sup_{n \to \infty} E X_n \leq \lim sup_{n \to \infty} E X = EX. \]

**Theorem 7.12** (Dominated convergence theorem). If $X_n \to X$ almost surely, $|X_n| \leq Y$ for all $n \geq 1$ and $E Y < \infty$, then $E X_n \to E X$.

*Proof.* Apply Fatou’s lemma separately to $Y + X_n$ and to $Y - X_n$.

### 7.4 Computing expected values

**Lemma 7.13.** If $X$ is a discrete r.v., that is, takes values in some countable set $S$, then
\[ EX = \sum_{s \in S} s P(X = s) \]
when the right-hand side is well-defined, i.e., when at least one of the numbers
\[ E(X_-) = \sum_{s \in S, s < 0} (-s) P(X = s), \quad E(X_+) = \sum_{s \in S, s \geq 0} s P(X = s) \]
is finite. It follows that for any function $g : \mathbb{R} \to \mathbb{R}$, we also have
\[ E(g(X)) = \sum_{s \in S} g(s) P(X = s). \]
Proof. If $S$ is finite then $X$ is a simple function, and can be written $X = \sum_{s \in S} s 1_{\{X = s\}}$, so this follows from the definition of $\mathbb{E}(\cdot)$ for simple functions. If $S$ is infinite this follows (check!) from the convergence theorems in the previous section by considering approximations to $X$ of the form $\sum_{s \in S, |s| < M} s 1_{\{X = s\}}$.

**Lemma 7.14.** If $X$ is a r.v. with a density function $f_X$, then

$$\mathbb{E}(X) = \int_{-\infty}^{\infty} x f_X(x) \, dx$$

when the right-hand side is well-defined, i.e., when at least one of the numbers

$$\mathbb{E}(X_-) = -\int_{-\infty}^{0} x f_X(x) \, dx, \quad \mathbb{E}(X_+) = \int_{0}^{\infty} x f_X(x) \, dx$$

is finite. Similarly, for any “reasonable” function $g$ we have

$$\mathbb{E}(g(X)) = \int_{-\infty}^{\infty} g(x) f_X(x) \, dx.$$ 

Proof. Fix $\epsilon > 0$, and approximate $X$ by a discrete r.v. $Y$, e.g.,

$$Y = \sum_{k=-\infty}^{\infty} k \epsilon 1_{\{k \epsilon < X \leq (k+1) \epsilon\}}.$$ 

Then $|\mathbb{E}(X) - \mathbb{E}(Y)| \leq \mathbb{E}|X - Y| \leq \epsilon$. By the previous lemma we have

$$\mathbb{E}(Y) = \sum_{k=-\infty}^{\infty} k \epsilon \mathbb{P}(k \epsilon < X \leq (k+1) \epsilon) = \sum_{k=-\infty}^{\infty} k \epsilon \int_{k \epsilon}^{(k+1) \epsilon} f_X(x) \, dx,$$

so the result for $\mathbb{E}X$ follows by letting $\epsilon \to 0$. For general functions $g(X)$ repeat this argument, and invoke the relevant convergence theorem to deduce that $\mathbb{E}(g(Y)) \to \mathbb{E}g(Y)$ as $\epsilon \to 0$.

**7.5 Expectation and independent random variables**

**Theorem 7.15.** (i) If $X, Y$ are independent r.v.’s then $\mathbb{E}(XY) = \mathbb{E}X \mathbb{E}Y$.

(ii) $X, Y$ are independent if and only if $\mathbb{E}[g(X)h(Y)] = \mathbb{E}g(X)\mathbb{E}h(Y)$ for all bounded measurable functions $g, h : \mathbb{R} \to \mathbb{R}$.
Sketch of proof. Part (i) follows either by approximation of $X, Y$ using simple functions, or using Fubini’s theorem, which you can read about in section 1.7 of [Dur2010] (Note that Fubini’s theorem in turn is proved by approximation using simple functions, so these two seemingly different approaches are really equivalent).

For part (ii), the “only if” follows from part (i) together with the observation that if $X, Y$ are independent then so are $g(X), h(Y)$. For the “if” part, observe that the function $1_{(a,b)}$ is a bounded measurable function, so in particular the condition $E[g(X)h(Y)] = E[g(X)]E[h(Y)]$ includes the information that $P(X \in I, Y \in J) = P(X \in I)P(Y \in J)$ for any two finite intervals $I, J$, which we already know is enough to imply independence.

**Theorem 7.16.** (i) If $X_1, X_2, \ldots, X_n$ are independent r.v.’s then $E(X_1 \ldots X_n) = \prod_{k=1}^n E[X_k]$. (ii) $X_1, \ldots, X_n$ are independent if and only if $E(\prod_{k=1}^n g_k(X_k)) = \prod_{k=1}^n E[g_k(X_k)]$ for all bounded measurable functions $g_1, \ldots, g_n : \mathbb{R} \to \mathbb{R}$.

The fact that expectation is multiplicative for independent random variables implies an important fact about the variance of a sum of independent r.v.’s. Let $X, Y$ be independent r.v.’s with finite variance. Then we get immediately that

$$V(X + Y) = E[((X - EX) + (Y - EY))^2]$$

$$= E(X - EX)^2 + E(Y - EY)^2 + 2E[(X - EX)(Y - EY)]$$

$$= V(X) + V(Y) + 0 = V(X) + V(Y).$$

More generally, if $X, Y$ are not necessarily independent, then we can define the covariance of $X$ and $Y$ by

$$\text{Cov}(X, Y) = E[(X - EX)(Y - EY)].$$

We then get the more general formula

$$V(X + Y) = V(X) + V(Y) + 2\text{Cov}(X, Y).$$

Repeating this computation with a sum of $n$ variables instead of just two, we get the following formula for the variance of a sum of r.v.’s.

**Lemma 7.17.** If $X_1, \ldots, X_n$ are r.v.’s with finite variance, then

$$V\left(\sum_{k=1}^n X_k\right) = \sum_{k=1}^n V(X_k) + 2 \sum_{1 \leq i < j \leq n} \text{Cov}(X_i, X_j).$$

41
Lemma 7.18 (Properties of the covariance). If \( X, Y \) are r.v.’s with finite variance, then:

1. \( \text{Cov}(X, Y) = \text{Cov}(Y, X) = \mathbb{E}(XY) - \mathbb{E}(X)\mathbb{E}(Y) \).
2. \( \text{Cov}(X, X) = \text{V}(X) \).
3. \( \text{Cov}(aX_1 + bX_2, Y) = a \text{Cov}(X_1, Y) + b \text{Cov}(X_2, Y) \)
4. \( \text{Cov}(X, aY_1 + bY_2) = a \text{Cov}(X, Y_1) + b \text{Cov}(X, Y_2) \)
5. If \( X, Y \) are independent then \( \text{Cov}(X, Y) = 0 \).
6. \( |\text{Cov}(X, Y)| \leq \sigma(X)\sigma(Y) \), with equality if and only if \( X \) and \( Y \) are linearly dependent.

Proof. Properties 1–5 are obvious. Property 6 follows by applying the Cauchy-Schwartz inequality to the r.v.’s \( X - \mathbb{E}X \) and \( Y - \mathbb{E}Y \).

If \( \text{Cov}(X, Y) = 0 \) we say that \( X \) and \( Y \) are uncorrelated, or orthogonal. This is a weaker condition than being independent, but because of the way the variance of a sum of r.v.’s behaves, it is still often useful for deriving bounds, as we shall see.

Define the correlation coefficient of \( X \) and \( Y \) by

\[ \rho(X, Y) = \frac{\text{Cov}(X, Y)}{\sigma(X)\sigma(Y)}. \]

This measures the correlation in units of the standard deviation of \( X \) and \( Y \) so does not depend on the choice of scale. From property 6 in the above lemma, we get that

\[ -1 \leq \rho(X, Y) \leq 1, \]

with equality on either side if and only if \( X \) and \( Y \) are linearly dependent.

7.6 Moments

For an integer \( k \geq 0 \), the \( k \)-th moment of a random variable \( X \) is the number \( \mathbb{E}(X^k) \). The \( k \)-th moment around a point \( c \in \mathbb{R} \) is the number \( \mathbb{E}(X - c)^k \). If \( c \) is not mentioned it is understood that the moment is around 0. The \( k \)-th central moment is the \( k \)-th moment around \( \mathbb{E}X \) (when it exists), i.e., \( \mathbb{E}(X - \mathbb{E}X)^k \). In this terminology, the variance is the second central moment.
The sequence of moments (usually around 0, or around \( \mathbb{E}X \)) often contains important information about the behavior of \( X \) and is an important computational and theoretical tool. Important special distributions often turn out to have interesting sequences of moments. Also note that by the monotonicity of the \( L_p \) norms (inequality (6) in Section 7.2), the set of values \( r \geq 0 \) such that \( \mathbb{E}(X^r) \) exists (one can also talk about \( r \)-th moments for non-integer \( r \), but that is much less commonly discussed) is an interval containing 0.

A nice characterization of the variance is that it is the minimal second moment. To compute the second moment around a point \( t \), we can write

\[
\mathbb{E}(X - t)^2 = \mathbb{E}[(X - \mathbb{E}X) - (t - \mathbb{E}X)]^2 \\
= \mathbb{E}(X - \mathbb{E}X)^2 + \mathbb{E}(t - \mathbb{E}X)^2 + 2(t - \mathbb{E}X)\mathbb{E}(X - \mathbb{E}X) \\
= \mathbb{V}(X) + (t - \mathbb{E}X)^2 \geq \mathbb{V}(X).
\]

So the function \( t \to \mathbb{E}(X-t)^2 \) is a quadratic polynomial that attains its minimum at \( t = \mathbb{E}X \), and the value of the minimum is \( \mathbb{V}(X) \). In words, the identity

\[
\mathbb{E}(X - t)^2 = \mathbb{V}(X) + (t - \mathbb{E}X)^2
\]

says that “the second moment around \( t \) is equal to the second moment around the mean \( \mathbb{E}X \) plus the square of the distance between \( t \) and the mean”. Note that this is analogous to (and mathematically equivalent to) the Huygens-Steiner theorem (also called the Parallel Axis theorem, see Wikipedia) from mechanics, which says that “the moment of inertia of a body with unit mass around a given axis \( L \) is equal to the moment of inertia around the line parallel to \( L \) passing through the center of mass of the body, plus the square of the distance between the two lines”. Indeed, the “moment” terminology seems to originate in this physical context.
Chapter 8: Laws of large numbers

Let $X_1, X_2, X_3, \ldots$ be a sequence of independent and identically distributed random variables. A common abbreviation for “independent and identically distributed” is i.i.d.. What this can mean is that we are taking repeated independent samples from some distribution, for example when doing a poll or an experiment in quantum mechanics (when doing a poll, it might be better to have the samples not be independent – after all, does it really make sense to call up the same person twice? But if the population is large the effect of having the samples be independent is negligible, and can make the analysis of the results a bit simpler).

Assume that $\mathbf{E}X_1$, the mean of $X_1$ (therefore of every $X_n$), is defined and finite, and denote it by $\mu$. In a real-life situation, we might not know what the mean is, and wish to estimate it. So we look at the sum of the first $n$ samples,

$$S_n = \sum_{k=1}^{n} X_k,$$

and use it to form the empirical average,

$$\bar{X}_n = \frac{1}{n} S_n = \frac{1}{n} \sum_{k=1}^{n} X_k.$$

The natural question is whether we can expect the empirical average to be close to the true mean $\mu = \mathbf{E}X_1$ as $n \to \infty$, and in what sense of “close”. A theorem or statement to that effect, making some assumptions, is called a law of large numbers. This can be generalized to a large extent to cases when the $X_n$’s are not identically distributed, or not independent, or both, etc. Thus, the “Law of Large Numbers” is not a single theorem in the normal sense of the word but rather a class of theorems, or even a “principle” or “meta-theorem” that you might hear a probabilist refer to in a somewhat vague, metaphorical way.

8.1 Weak laws of large numbers

**Theorem 8.1** (Weak Law of Large Numbers (WLLN)). If $\mathbf{E}|X_1| < \infty$ then

$$\frac{S_n}{n} \xrightarrow{\mathbb{P}} \mu.$$
Proof in the case of finite variance. In the most general case, proving this requires some work – we shall deduce it from its stronger cousin, the Strong Law of Large Numbers. However, if we assume that \( \sigma^2 = \mathbf{V}(X_1) < \infty \), the proof is extremely easy! It suffices to note that in this case \( \mathbf{V}(S_n) = n\sigma^2 \) (this is true even when the \( X_n \)'s are not independent but only uncorrelated), or \( \mathbf{V}(S_n/n) = \sigma^2/n \). From Chebyshev’s inequality we then have that for any \( \epsilon > 0 \),

\[
P(|n^{-1}S_n - \mu| > \epsilon) \leq \frac{\sigma^2}{n\epsilon^2} \xrightarrow{n\to\infty} 0.
\]  

(7)

\[
\square
\]

8.2 Strong laws of large numbers

Our goal in this section will be to prove:

**Theorem 8.2** (Strong Law of Large Numbers (SLLN)). If \( E|X_1| < \infty \) then

\[
\frac{S_n}{n} \xrightarrow{a.s.} \mu.
\]

As in the case of the weak law, it turns out that this is easier to prove when making more restrictive assumptions about the distribution of \( X \), and specifically about the existence of moments. So we will prove it several times, successively weakening our assumptions until we get to the most general (but least easy to prove) result.

Proof in the case of a finite fourth moment. To prove that \( S_n/n \to \mu \), we want to prove that \( P(|S_n/n - \mu| > \epsilon \text{ i.o.}) = 0 \). Looking at the bound (7), we see that if the bound \( \sigma^2/n\epsilon^2 \) were to form the \( n \)-th general term of a convergent series, then by the Borel-Cantelli lemma this would be enough to get the desired consequence. This is not the case, but if we assume that \( X_1 \) has a finite fourth moment, then we could do a similar trick that will give a convergent series. In that case, using Markov’s inequality we can get that

\[
P(|S_n/n - \mu| > \epsilon) = P\left(\left(\sum_{k=1}^{n} (X_k - \mu)\right)^4 > n^4\epsilon^4\right) \leq \frac{E(S_n - n\mu)^4}{n^4\epsilon^4}.
\]  

(8)
Denote $\hat{X}_k = X_k - \mu$, and $T_n = S_n - n\mu = \sum_{k=1}^n \hat{X}_k$. To bound $E(T_n^4)$, note that we can write

$$T_n^4 = \sum_{k=1}^n \hat{X}_k^4 + \binom{4}{1} \sum_{1 \leq i \neq j \leq n} \hat{X}_i^3 \hat{X}_j + \frac{1}{2} \binom{4}{2} \sum_{1 \leq i \neq j \leq n} \hat{X}_i^2 \hat{X}_j^2$$

$$+ \frac{1}{2} \binom{4}{2,1,1} \sum_{1 \leq i,j,k \leq n} \hat{X}_i^2 \hat{X}_j \hat{X}_k + \frac{1}{4!} \binom{4}{1,1,1,1} \sum_{1 \leq i,j,k,\ell \leq n} \hat{X}_i \hat{X}_j \hat{X}_k \hat{X}_\ell$$

(where $\binom{4}{2,1,1} = 4!/2!1!1!$, $\binom{4}{1,1,1,1} = 4!/1!1!1!1!$ are multinomial coefficients). Now take the expectations on both sides, and use the fact that $E(\hat{X}_k) = 0$ and that the $\hat{X}_k$'s are independent, to get

$$E(T_n^4) = nm_4 + 3n(n-1)m_2^2,$$

where we denote $m_2 = E(\hat{X}_k^2) = V(X_k)$, $m_4 = E(\hat{X}_k^4) < \infty$. This gives us the bound we wanted! In fact, all that matters is that $E(T_n^4) \leq Cn^2$ for some constant $C > 0$. Combining this with (8), we get that

$$P(\|S_n/n - \mu\| > \epsilon) \leq \frac{C}{n^2 \epsilon^4}.$$

In particular, we have that $\sum_{n=1}^\infty P(\|S_n/n - \mu\| > \epsilon) < \infty$, so by the Borel-Cantelli lemma, the probability of the event

$$A_\epsilon := \{|S_n/n - \mu| > \epsilon \text{ i.o.}\}$$

is 0. This is true for all $\epsilon > 0$, therefore the probability of

$$\{S_n/n \nrightarrow \mu\} \subset \bigcup_{\epsilon > 0} A_\epsilon = \bigcup_{n=1}^\infty A_{1/n}$$

is also 0, since it is contained in a countable union of events of probability 0.

\[\square\]

**Proof in the case of finite variance.** We are slowly refining our techniques to weaken the assumptions required to prove the SLLN. The following nice proof manages to harness the Chebyshev variance bound (7) after all to deduce the theorem in the case of r.v.’s with finite variance. Observe that while the series of terms on the right-hand side of (7) diverges, if we restrict it to a subsequence $n_k = k^2$, it will become a convergent series: $\sum_{k=1}^\infty \sigma^2/k^2 \epsilon^2 < \infty$. This implies, again by the Borel-Cantelli lemma, that

$$P(\|S_{n_k}/n_k - \mu\| > \epsilon \text{ i.o.}) = 0$$

46
for all $\epsilon > 0$ (the “i.o.” here refers to the “running index” $k$, not $n$). This implies as before that

$$P\left(\frac{S_{nk}}{n} \xrightarrow{a.s.} \mu\right) = 1.$$  

So, while we have not shown almost sure convergence of the empirical averages to the true mean for all values of $n$, at least we have done so for the subsequence $n_k = k^2$. But this subsequence is relatively dense. In particular, if we show that in between elements of the subsequence $n_k = k^2$, the empirical average cannot fluctuate too wildly, then the theorem would follow. This will again follow from a combination of variance-based (i.e., Chebyshev) bounds and the Borel-Cantelli lemma. Fix some $k$, and take an integer $n$ satisfying $n_k \leq n < n_{k+1}$. How likely is the $n$-th empirical average to deviate significantly from the $n_k$-th empirical average? Using the notation $T_n = S_n - n\mu$ as before, we have

$$P \left( \left| \frac{T_n}{n} - \frac{T_{nk}}{n} \right| > \epsilon \right) = P \left( \left| \frac{n_k T_n - nT_{nk}}{n \cdot n_k} \right| > \epsilon \right)$$

(by triangle ineq.) \leq P \left( \left| \frac{T_n - T_{nk}}{n_k} \right| > \epsilon/2 \right) + P \left( \left| \frac{T_n}{n} - \frac{n-n_k}{n \cdot n_k} \right| > \epsilon/2 \right)

(by Chebyshev's ineq.) \leq \frac{4\text{Var}(T_n - T_{nk})}{\epsilon^2 n_k^2} + \frac{4\text{Var}(T_n)(n-n_k)^2}{n^2 n_k^2}

\leq \frac{10k\sigma^2}{\epsilon^2 k^4} + \frac{20k^4\sigma^2}{k^8} < \frac{20\sigma^2}{k^3},

where we have denoted $\sigma^2 = \text{Var}(X_1)$.

The estimate that we obtained is valid for a single $n$. We are actually interested in the maximal fluctuation of the empirical averages $S_n/n$ from $S_{nk}/n_k$, when $n$ ranges in the interval $[n_k, n_{k+1})$. By a simple subadditivity argument, usually referred to as a union bound (i.e., bounding the probability of a union of events by the sum of the probabilities, which is the most naive bound you can imagine), we get easily that

$$P \left( \max_{n_k \leq n < n_{k+1}} \left| \frac{T_n}{n} - \frac{T_{nk}}{n_k} \right| > \epsilon \right) = P \left( \bigcup_{n_k \leq n < n_{k+1}} \left\{ \left| \frac{T_n}{n} - \frac{T_{nk}}{n_k} \right| > \epsilon \right\} \right)$$

\leq \sum_{n=n_k}^{n_{k+1}-1} P \left( \left| \frac{T_n}{n} - \frac{T_{nk}}{n_k} \right| > \epsilon \right) < \frac{20\sigma^2 \cdot 2k}{k^3} = \frac{40\sigma^2}{k^2}.

Once again, we have obtained as our bound the general term of a convergent series! Denoting

$$A_{k,\epsilon} = \left\{ \max_{n_k \leq n < n_{k+1}} \left| \frac{T_n}{n} - \frac{T_{nk}}{n_k} \right| > \epsilon \right\},$$

47
by the Borel-Cantelli lemma this implies that for any $\epsilon > 0$, $P(A_{k, \epsilon} \text{ i.o.}) = 0$ (with the “i.o.” qualifier again referring to the running index $k$). What about the chance that this will happen for some $\epsilon > 0$? After all, there are so many $\epsilon$’s out there... But no, we also get that

$$P\left(\bigcup_{\epsilon > 0} \{A_{k, \epsilon} \text{ i.o.}\}\right) = P\left(\bigcup_{m=1}^{\infty} \{A_{k,1/m} \text{ i.o. (w.r.t. $k$)}\}\right) = 0,$$

by subadditivity for countable unions and the fact that $A_{k, \epsilon} \subset A_{k, \epsilon'}$ if $\epsilon > \epsilon'$.

Finally, combining our two main results, namely that the two events $E_1 = \{S_{n_k}/n_k \xrightarrow{n \to \infty} \mu\}$ and $E_2 = \left(\bigcup_{m=1}^{\infty} \left\{\max_{n_k \leq n < n_k+1} \frac{|T_n - T_{n_k}|}{n_k} > \frac{1}{m} \text{ for infinitely many } k's\right\}\right)^c$ both have probability 1, we get that their intersection $E_1 \cap E_2$ also has probability 1. But we have the event inclusion

$$E_1 \cap E_2 \subset \left\{\frac{S_n}{n} \xrightarrow{n \to \infty} \mu\right\}$$

(if the conditions in both the events $E_1, E_2$ occur, then $S_n/n$ must converge to $\mu$), so this latter event also has probability 1.

The above proof was a little involved, but is based on a few simple ideas: 1. Use Chebyshev bounds together with the Borel-Cantelli lemma. 2. Break up the event $\{S_n/n \rightarrow \mu\}$ in a clever way into events which can be managed using this technique, namely (in this case) the weaker convergence along the subsequence $n_k = k^2$, and separately the control of the fluctuations of the empirical averages in each range $[n_k, n_{k+1})$ between successive elements of the subsequence.

An extra benefit of the above proof is that it doesn’t use the full power of the assumption that the $X_n$’s are independent. In fact, everything is based on variance computations of sums of the $X_k$’s, so the proof works equally well for uncorrelated random variables!

**Theorem 8.3** (SLLN for uncorrelated r.v.’s with finite variance). If $X_1, X_2, \ldots$ are a sequence of uncorrelated and identically distributed r.v.’s with finite variance, then

$$\frac{1}{n} \sum_{k=1}^{n} X_k \xrightarrow{a.s.} E X_1.$$
Finally, we turn to the proof of the full SLLN for an i.i.d. sequence (Theorem 8.2), assuming only a finite first moment. Etemadi's 1981 proof presented in [Dur2010] is based on a similar idea of proving convergence first for a subsequence, and introduces another useful technique, that of truncation.

**Proof of Theorem 8.2.** First, observe that it is enough to prove the theorem in the case where $X_1 \geq 0$, since in the general case we may decompose each $X_n$ into its positive and negative parts, and this gives two i.i.d. sequences of nonnegative r.v.'s. The validity of the SLLN for each of the two sequences implies the result for their difference.

Second, for each $n \geq 1$ let $Y_n = X_n - 1_{\{X_n \leq n\}}$ (“$X_n$ truncated at $n$”), and denote $T_n = Y_1 + Y_2 + \ldots + Y_n$. Since $E(X_1) < \infty$, by a homework exercise we know that $\sum_{n=1}^{\infty} P(X_n > n) < \infty$, which by the Borel-Cantelli lemma implies that $P(X_n > n \text{ i.o.}) = P(X_n \neq Y_n \text{ i.o.}) = 0$. It follows that the event

$$\left\{ \sup_{n \to \infty} |S_n - T_n| = \infty \right\}$$

has probability 0, and therefore the even smaller event

$$\left\{ \limsup_{n \to \infty} \left| \frac{S_n}{n} - \frac{T_n}{n} \right| > 0 \right\} = \left\{ \limsup_{n \to \infty} \left| \left( \frac{S_n}{n} - \mu \right) - \frac{T_n - E(T_n)}{n} \right| > 0 \right\},$$

has probability 0 (the equivalence between these last two events follows from the observation that $E(Y_n) \uparrow \mu$ by the monotone/dominated convergence theorems, and therefore also $E(T_n)/n \to \mu$ as $n \to \infty$ since $(E(T_n))_{n=1}^{\infty}$ is the sequence of arithmetic averages of the $E(Y_n)$’s). So we have shown that to prove the theorem, it is enough to prove that

$$P\left( \frac{T_n - ET_n}{n} \to 0 \right) = 1.$$

Now, to prove this, as before we establish a.s. convergence first along a subsequence $n_k$, this time taking $n_k = \lceil \alpha^k \rceil$ where $\alpha > 1$. (Here, $\lceil x \rceil$ denotes the “floor” function, namely the largest integer $\leq x$). This is done by again combining the Borel-Cantelli lemma with a Chebyshev variance bound, except that showing that the sum of the bounds gives a convergent series requires more work than before. We have

$$P\left( \left| \frac{T_{n_k}}{n_k} - \frac{E(T_{n_k})}{n_k} \right| > \epsilon \right) \leq \frac{V(T_{n_k})}{\epsilon^2 n_k^2} = \frac{1}{\epsilon^2 n_k^2} \sum_{m=1}^{n_k} V(Y_m).$$

49
Therefore

\[ \sum_{k=1}^{\infty} \mathbb{P} \left( \left| \frac{T_{n_k}}{n_k} - \mathbb{E}(T_{n_k}) \right| > \epsilon \right) \leq \sum_{k=1}^{\infty} \frac{1}{\epsilon^2 n_k^2} \sum_{m=1}^{n_k} \mathbb{V}(Y_m) = \frac{1}{\epsilon^2} \sum_{m=1}^{\infty} \mathbb{V}(Y_m) \sum_{n_k \geq m} \frac{1}{n_k^2} \leq \frac{1}{\epsilon^2} \sum_{m=1}^{\infty} \mathbb{V}(Y_m) \frac{1}{m^2} (1 + \alpha^{-2} + \alpha^{-4} + \alpha^{-6} + \ldots) = \frac{1}{\epsilon^2 (1 - \alpha^{-2})} \sum_{m=1}^{\infty} \frac{\mathbb{V}(Y_m)}{m^2} \]  

(9)

Lemma 8.4. We have

\[ \sum_{m=1}^{\infty} \frac{\mathbb{V}(Y_m)}{m^2} \leq 4\mathbb{E}X_1 < \infty. \]

Exercise 8.5. Prove this. You can use the formula \( \mathbb{E}(Z) = \int_0^\infty \mathbb{P}(Z > x) \, dx \) that’s valid for any nonnegative r.v. \( Z \).

It follows that the infinite sum on the left-hand side of (9) converges, and therefore by the Borel-Cantelli lemma, we have that

\[ \mathbb{P} \left( \left| \frac{T_{n_k}}{n_k} - \mathbb{E}(T_{n_k}) \right| > \epsilon \text{ infinitely often (w.r.t. } k) \right) = 0. \]

Since this is true for all \( \epsilon > 0 \), using the standard trick we get that

\[ \mathbb{P} \left( \frac{T_{n_k}}{n_k} - \frac{\mathbb{E}(T_{n_k})}{n_k} \xrightarrow{k \to \infty} 0 \right) = \mathbb{P} \left( \frac{T_{n_k}}{n_k} \xrightarrow{k \to \infty} \mu \right) = 1. \]

The last step is now to show that convergence along this subsequence forces \( (T_n - \mathbb{E}T_n)/n \) to behave well between successive \( n_k \)'s. Observe that if \( n_k \leq n < n_{k+1} \) then

\[ \frac{T_{n_k}}{n_{k+1}} \leq \frac{T_n}{n} \leq \frac{T_{n_{k+1}}}{n_k}. \]

Since \( n_k = \lfloor \alpha^k \rfloor \), in the limit this gives that almost surely the bounds

\[ \frac{1}{\alpha \mu} \leq \liminf_{n \to \infty} \frac{T_n}{n} \leq \limsup_{n \to \infty} \frac{T_n}{n} \leq \alpha \mu \]

hold. Since \( \alpha > 1 \) was arbitrary, the intersection of these events for \( \alpha = 1 + 1/d, \ d = 1, 2, \ldots \), implies that

\[ \mathbb{P} \left( \frac{T_n}{n} \to \mu \right) = 1, \]

which finishes the proof. \( \square \)
Solution to Exercise 8.5.

\[ \sum_{m=1}^{\infty} \frac{\text{Var}(Y_m)}{m^2} \leq \sum_{m=1}^{\infty} \frac{1}{m^2} \mathbb{E}(Y_m^2) = \sum_{m=1}^{\infty} \frac{1}{m^2} \mathbb{E}(X_m^2 1_{X_m \leq m}) \]

\[ = \sum_{m=1}^{\infty} \frac{1}{m^2} \int_0^{\infty} \mathbb{P}(X_m^2 1_{X_m \leq m} > t) \, dt \]

\[ = \sum_{m=1}^{\infty} \frac{1}{m^2} \int_0^{\infty} \mathbb{P}(\sqrt{t} \leq X_m \leq m) \, dt \]

\[ = \sum_{m=1}^{\infty} \frac{1}{m^2} \int_0^{m^2} \mathbb{P}(\sqrt{t} \leq X_1 \leq m) \, dt \]

\[ \leq \sum_{m=1}^{\infty} \frac{1}{m^2} \int_0^{m^2} \mathbb{P}(X_1 \geq \sqrt{t}) \, dt \]

\[ = \int_0^{\infty} \left( \sum_{m \geq \sqrt{t}} \frac{1}{m^2} \right) \mathbb{P}(X_1 \geq \sqrt{t}) \, dt \]

\[ \leq \int_0^{\infty} \frac{2}{\sqrt{t}} \mathbb{P}(X_1 \geq \sqrt{t}) \, dt = 4 \int_0^{\infty} \mathbb{P}(X_1 \geq u) \, du = 4 \mathbb{E}(X_1) \]
Chapter 9: Applications and further examples

9.1 The Weierstrass approximation theorem

As an application of WLLN (or, rather, of Chebyshev’s inequality), we prove the following theorem in analysis, which seems to have no connection to probability whatsoever.

Theorem 9.1 (The Weierstrass approximation theorem). If \( f : [0,1] \rightarrow \mathbb{R} \) is a continuous function, then \( f \) can be uniformly approximated by polynomials. That is, for any \( \epsilon > 0 \) there exists a polynomial \( p \) such that

\[
||f - p|| := \max_{x \in [0,1]} |f(x) - p(x)| < \epsilon.
\]

Proof. Let \( f : [0,1] \rightarrow \mathbb{R} \) be a continuous function. Define the sequence of Bernstein polynomials of \( f \) by

\[
B_n(x) = B_n^f(x) = \sum_{k=0}^{n} f\left(\frac{k}{n}\right) \binom{n}{k} x^k (1-x)^{n-k}.
\]

We claim that \( ||B_n - f|| \rightarrow 0 \) as \( n \rightarrow \infty \), which will prove the theorem. We will prove this by giving a probabilistic interpretation to \( B_n \). Indeed, fix \( x \in [0,1] \), and let \( X_1, X_2, \ldots \) be a sequence of i.i.d. r.v.’s with the Bernoulli distribution \( \text{Binom}(1, x) \). Denote \( S_n = \sum_{k=1}^{n} X_k \). Then it is easy to see that

\[
B_n(x) = \mathbb{E}_x \left[ f\left(\frac{S_n}{n}\right) \right],
\]

where the notation “\( \mathbb{E}_x \)” just means taking the expectation, while at the same time highlighting the fact that the distribution of \( S_n \) depends on the parameter \( x \).

Now the idea is that since the law of large numbers implies that \( S_n/n \) is with high probability close to its mean \( x \), and \( f \) is a continuous function, then \( f(S_n/n) \) should with high probability be close to \( f(x) \), and therefore also the average value of \( f(S_n/n) \), namely \( B_n(x) \), should be close to \( f(x) \), which is what we want. However, we want to make this claim uniformly in \( x \), so instead of invoking the WLLN (Theorem 8.1) we have to go back and look “under the hood” at Chebyshev’s inequality which we used to prove it. We estimate \( |B_n(x) - f(x)| \) as follows. Fix some arbitrary \( \epsilon > 0 \). Let \( \delta > 0 \) be such that for any \( u, v \in [0,1] \), if \( |u - v| < \delta \) then \( |f(u) - f(v)| < \epsilon \) (this is guaranteed to exist because \( f \) is
uniformly continuous on \([0, 1]\)). Then
\[
|B_n(x) - f(x)| = \left| \mathbb{E}_x f \left( \frac{S_n}{n} \right) - f(x) \right| \leq \mathbb{E}_x \left| f \left( \frac{S_n}{n} \right) - f(x) \right|
\]
\[
= \mathbb{E}_x \left[ \left| f \left( \frac{S_n}{n} \right) - f(x) \right| 1_{\{|\frac{S_n}{n} - x| > \delta\}} \right] + \mathbb{E}_x \left[ \left| \frac{S_n}{n} - f(x) \right| 1_{\{|\frac{S_n}{n} - x| \leq \delta\}} \right]
\]

In this last expression, each of the two expectations is small for a different reason. The second expectation is bounded by \(\epsilon\), since on the event that \(|S_n/n - x| \leq \delta\), we have that \(|f(S_n/n) - f(x)| < \epsilon\). To bound the first expectation, denote \(M = \|f\| := \max_{x \in [0,1]} |f(x)| < \infty\). Then, by bounding the difference of \(f\)-values by \(2M\) and then using Chebyshev’s inequality, we get
\[
\mathbb{E}_x \left[ \left| f \left( \frac{S_n}{n} \right) - f(x) \right| 1_{\{|\frac{S_n}{n} - x| > \epsilon\}} \right] \leq 2M \cdot \mathbb{P}_x \left( \left| \frac{S_n}{n} - x \right| > \epsilon \right) \leq \frac{2M \sigma^2(X_1)}{n \epsilon^2} = \frac{2M x(1-x)}{n \epsilon^2}
\]

This bound converges to 0, not just for a single \(x\) but (fortunately for us) uniformly in \(x \in [0, 1]\), since it is bounded from above by \(M/(2n \epsilon^2)\). So we have shown that
\[
\|B_n - f\| = \max_{x \in [0,1]} |B_n(x) - f(x)| \leq \epsilon + \frac{M}{2n \epsilon^2}.
\]
It follows that \(\limsup_{n \to \infty} \|B_n - f\| \leq \epsilon\), and since \(\epsilon\) was an arbitrary positive number the result follows.

9.2 Infinite expectations and triangular arrays

After treating the “classical” case of an i.i.d. sequence with finite expectations, let’s turn to slightly more exotic situations. First, what happens if the expectation is infinite? For the strong law, the following result shows that we have no hope of having convergence in a meaningful sense.

**Theorem 9.2** (Converse to SLLN). If \(X_1, X_2, \ldots\), is an i.i.d. sequence of r.v.’s with \(\mathbb{E}|X_1| = \infty\), then
\[
\mathbb{P} \left( \exists \lim_{n \to \infty} \frac{1}{n} \sum_{k=1}^{n} \right) = 0.
\]

**Proof.** See homework.

What about the weak law? It turns out that a weak law can still hold in certain situations with infinite expectations, although one has to consider a generalized empirical average where
the sum of the first \( n \) samples is divided by a quantity growing faster than \( n \). Rather than develop a complete theory, we will consider the particular example of the **St. Petersburg Lottery**. In this example, the winning in a single round of lottery is an integer-valued random variable with the following distribution:

\[
P(X = 2^k) = 2^{-k}, \quad k = 1, 2, 3, \ldots
\]

Let \( X_1, X_2, \ldots \), be an i.i.d. sequence with the same distribution, and let \( S_n = \sum_{k=1}^{n} X_k \). How much should you agree to pay to be allowed to play this lottery \( n \) times? (Even the seemingly simple case \( n = 1 \) of this question has been a subject of quite some debate by economists! See [http://en.wikipedia.org/wiki/St._Petersburg_paradox](http://en.wikipedia.org/wiki/St._Petersburg_paradox). In other words, how big should we expect \( S_n \) to be, with probability close to 1?

**Theorem 9.3.**

\[
\frac{S_n}{n \log_2 n} \xrightarrow{n \to \infty} 1.
\]

In other words, to be allowed to pay the game \( n \) times when \( n \) is large (and assuming the payoff is in dollars), it may be considered reasonable to pay exactly (or even better, slightly less than) \( \log_2 n \) dollars per round played. For example, if \( n = 1024 \) you would be paying $10 per round.

**Proof.** The proof uses a truncation idea similar to the one we saw in the proof of SLLN, except that for each \( n \) we will truncate the first \( n \) variables at a level which is a function of \( n \). Denote \( b_n = n \log_2 n \), \( Y_{n,k} = X_k \mathbb{1}_{\{X_k < b_n\}} \), \( T_n = \sum_{k=1}^{n} Y_{n,k} \), and \( a_n = \mathbb{E}(T_n) \). We will prove that

\[
\frac{S_n - a_n}{b_n} \xrightarrow{n \to \infty} 0. \tag{10}
\]

First we check that this is enough, by estimating \( a_n \):

\[
a_n = \sum_{k=1}^{n} \mathbb{E}(Y_{n,k}) = \sum_{k=1}^{n} \mathbb{E}(X_k \mathbb{1}_{\{X_k < b_n\}}) = \sum_{k=1}^{n} \left( \frac{1}{2} \cdot 2 + \frac{1}{4} \cdot 4 + \frac{1}{8} \cdot 8 + \ldots + \frac{1}{2^{m_n}} \cdot 2^{m_n} \right)
\]

where \( m_n \) is the largest integer such that \( 2^{m_n} \leq b_n \), or in other words \( m_n = \lfloor \log_2 n + \log_2 \log_2 n \rfloor \), which gives

\[
a_n = \sum_{k=1}^{n} \left[ \log_2 n + \log_2 \log_2 n \right] = n \log_2 n + O(n \log_2 \log_2 n),
\]

54
so $a_n$ indeed behaves like $n \log_2 n$ up to first-order asymptotics. Now to prove (10), note that for any $\epsilon > 0$,

$$
P \left( \left| \frac{S_n - a_n}{b_n} \right| > \epsilon \right) \leq P(T_n \neq S_n) + P \left( \left| \frac{T_n - a_n}{b_n} \right| > \epsilon \right). \tag{11}$$

In this bound, the first term is bounded by

$$
\sum_{k=1}^{n} P(Y_{n,k} \neq X_k) = \sum_{k=1}^{n} P(X_k > b_n) \leq \sum_{k=1}^{n} \frac{2}{b_n} \leq \frac{2}{\log_2 n} \quad n \to \infty.
$$

To bound the second term, use Chebyshev’s inequality and the fact that $V(Y_{n,k}) \leq E(Y_{n,k}^2)$ to write

$$
P \left( \left| \frac{T_n - a_n}{b_n} \right| > \epsilon \right) \leq \frac{V(T_n)}{\epsilon^2 b_n^2} \leq \frac{1}{\epsilon^2 b_n^2} \sum_{k=1}^{n} E(Y_{n,k}^2)
$$

$$
\leq \frac{1}{\epsilon^2 b_n^2} \sum_{k=1}^{n} \left( \frac{1}{2} \cdot 2^2 + \frac{1}{4} \cdot 4^2 + \frac{1}{8} \cdot 8^2 + \ldots + \frac{1}{2^{m_n}} \cdot 2^{2m_n} \right)
$$

$$
\leq \frac{1}{\epsilon^2 b_n^2} \sum_{k=1}^{n} 2 \cdot 2^{m_n} \leq \frac{2}{\epsilon^2 b_n^2} \sum_{k=1}^{n} b_n = \frac{2}{\epsilon^2 \log_2 n} \quad n \to \infty.
$$

We conclude that the left-hand side of (11) converges to 0, as $n \to \infty$, which finishes the proof. \qed

Another twist on laws of large numbers comes when we replace the notion of an i.i.d. sequence by a more general notion of a triangular array. In this case, for each $n$ we have a sequence $X_{n,1}, X_{n,2}, \ldots, X_{n,n}$ of independent, but not necessarily identically distributed, and we denote $S_n = \sum_{k=1}^{n} X_{n,k}$ – this is the sum of the samples in the $n$-th experiment. Here, for each $n$ there could be a separate experiment involving $n$ different r.v.’s, and the r.v.’s $X_{n,k}$ and $X_{m,j}$ for $n \neq m$ are not even assumed to be defined on the same probability space, let alone to be independent of each other.

Again, instead of giving general conditions for a law of large numbers to hold, consider the following example of the so-called coupon collector’s problem: A brand of breakfast cereals comes with a small toy chosen uniformly at random from a set of $n$ possible kinds of toys. A collector will buy more boxes of cereals until she has collected all $n$ different toys. Denote by $T_n$ the number of boxes she ends up buying. What can we say about the size of $T_n$? Fortunately, we can represent it as a sum of independent r.v.’s, by writing

$$
T_n = X_{n,1} + X_{n,2} + X_{n,3} + \ldots + X_{n,n},
$$
where

\[ X_{n,1} = \text{number of boxes purchased to get one kind of toy} = 1, \]
\[ X_{n,2} = \text{number of boxes purchased after having one toy to get a different kind}, \]
\[ X_{n,3} = \text{number of boxes purchased after having two kinds of toys to get a third kind}, \]
\[ \vdots \]
\[ X_{n,n} = \text{number of boxes purchased after having } n-1 \text{ kinds of toys to get the last kind}. \]

Clearly these r.v.'s are independent. Furthermore, \( X_{n,k} \) is a geometric r.v. with parameter \( p_{n,k} = \frac{n-k+1}{n} \). This gives us that

\[
E(T_n) = \sum_{k=1}^{n} E(X_{n,k}) = \sum_{k=1}^{n} \frac{n}{n-k+1} = n \left( \frac{1}{n} + \frac{1}{n-1} + \ldots + \frac{1}{2} + \frac{1}{1} \right) = nH_n,
\]

where \( H_n = \sum_{k=1}^{n} \frac{1}{k} \) is the \( n \)-th harmonic number, and

\[
\text{Var}(T_n) = \sum_{k=1}^{n} \text{Var}(X_{n,k}) = \sum_{k=1}^{n} \frac{k-1}{n} \left( \frac{n}{n-k+1} \right)^2 \leq n^2 \sum_{k=1}^{n} \frac{1}{k^2} \leq 2n^2
\]

(in this example, we only need a bound for \( \text{Var}(T_n) \), but it is possible also to get more precise asymptotics for this quantity). It follows using Chebyshev’s inequality that for each \( \epsilon > 0 \),

\[
P \left( \frac{T_n - nH_n}{n \log n} > \epsilon \right) \leq \frac{\text{Var}(T_n)}{\epsilon^2 n^2 (\log n)^2} \leq \frac{2}{\epsilon^2 (\log n)^2} \overset{n \to \infty}{\longrightarrow} 0,
\]

so \( (T_n - nH_n)/(n \log n) \) converges in probability to 0, and therefore we get that

\[
\frac{T_n}{n \log n} \overset{P}{\longrightarrow} 1.
\]

The lesson to be learned from the above examples is that some naturally-occurring problems in real life lead to more complicated situations than can be modeled with an i.i.d. sequence with finite mean; but often such problems can be analyzed anyway using the same ideas and techniques that we developed. In probability textbooks you can find a general treatment of various conditions under which a triangular array of independent random variables satisfies a (strong or weak) law of large numbers.
9.3 Random series of independent samples

We now look at the related topic of infinite series of independent r.v.’s. When can such a series be said to converge? A key technical result that will help us answer this question in some cases is the following beautiful inequality due to Kolmogorov.

**Theorem 9.4 (Kolmogorov’s maximal inequality).** Assume that $X_1, X_2, \ldots, X_n$ are independent r.v.’s with finite variances, and let $S_k = \sum_{j=1}^{k} X_j$. Then

$$
P \left( \max_{1 \leq k \leq n} |S_k - E(S_k)| > t \right) \leq \frac{V(S_n)}{t^2} = \frac{\sum_{k=1}^{n} \sigma^2(X_k)}{t^2}.
$$

Before we start the proof, note that the bound on the right-hand side is the usual variance bound that follows from Chebyshev’s inequality; except that the event on the left-hand side whose probability this quantity bounds is a much bigger event than the usual deviation event $\{ |S_n - E(S_n)| > t \}$ for which we know the Chebyshev bound holds!

**Proof.** We may assume without loss of generality that $E(X_k) = 0$ for all $k$. Denote

$$A = \left\{ \max_{1 \leq k \leq n} |S_k| > t \right\},$$

and define events $A_1, A_2, \ldots, A_n$ by

$$A_k = \left\{ |S_k| \geq t, \max_{1 \leq j < k} |S_j| < t \right\}.$$

In words, $A_k$ is the event that the sequence of cumulative sums $(S_j)_{j=1}^{n}$ exceeded $t$ in absolute value for the first time at time $k$. Note that these events are disjoint and their union is the event $A$ whose probability we are trying to bound. As a consequence, we can lower-bound the variance $V(S_n) = E(S_n^2)$ of $S_n$, as follows:

$$E(S_n^2) \geq E(S_n^2 1_A) = \sum_{k=1}^{n} E(S_n^2 1_{A_k}) = \sum_{k=1}^{n} E((S_k + (S_n - S_k))^2 1_{A_k})$$

$$= \sum_{k=1}^{n} \left[ E(S_k^2 1_{A_k}) + E((S_n - S_k)^2 1_{A_k}) + 2E((S_k 1_{A_k})(S_n - S_k)) \right].$$

In this last expression, the terms $E((S_k 1_{A_k})(S_n - S_k))$ are equal to 0, since $S_k 1_{A_k}$ is a random variable that depends only on $X_1, \ldots, X_k$ and hence independent of $S_n - S_k$, which
depends only on the values of $X_{k+1}, \ldots, X_n$, which causes the expectation of their product to be equal to the product of the expectations, which is 0. Furthermore, the middle terms $E[(S_n - S_k)^2 1_{A_k}]$ are all nonnegative, and each of the first terms $E(S_k^2 1_{A_k})$ satisfies
\[
E(S_k^2 1_{A_k}) \geq E(t^2 1_{A_k}) = t^2 P(A_k),
\]
since on the event $A_k$ we know that $S_k^2$ is at least $t^2$ (look again at the definition of $A_k$). Combining these observations, we get that
\[
V(S_n) \geq t^2 \sum_{k=1}^n P(A_k) = t^2 P(A),
\]
which is exactly the claim that was to be proved. \qed

As a corollary, we get a result on convergence of random series.

**Theorem 9.5.** Let $X_1, X_2, \ldots$ be a sequence of independent r.v.'s such that $E(X_n) = 0$ for all $n$, and assume that $\sum_{n=1}^\infty V(X_n) < \infty$. Then the random series $\sum_{n=1}^\infty X_n$ converges almost surely.

**Proof.** Denote as usual $S_n = \sum_{k=1}^n X_k$. We have the following equality of events:
\[
\left\{ \sum_{n=1}^\infty X_n \text{ converges} \right\} = \left\{ \left( \sum_{n=1}^N X_n \right)_{N \geq 1} \text{ is a Cauchy sequence} \right\} = \bigcap_{\epsilon > 0} \bigcup_{N \geq 1} \bigcap_{n \geq N} \left\{ |S_n - S_N| < \epsilon \right\}.
\]
Or, put differently, we can look at the complement of this event and represent it as
\[
\left\{ \sum_{n=1}^\infty X_n \text{ does not converge} \right\} = \bigcup_{\epsilon > 0} \bigcap_{N \geq 1} \bigcup_{n \geq N} \left\{ |S_n - S_N| \geq \epsilon \right\} = \bigcup_{\epsilon > 0} \bigcap_{N \geq 1} \left\{ \sup_{n \geq N} |S_n - S_N| \geq \epsilon \right\}.
\]
This form is exactly suitable for an application of the Kolmogorov’s maximal inequality, except that here we have an infinite sequence of partial sums instead of a finite maximum.
However, by the “continuity from below” property of probability measures, we see that it does not matter. More precisely, for any $\epsilon > 0$ and $N \geq 1$, we have

$$P \left( \sup_{n \geq N} |S_n - S_N| \geq \epsilon \right) = \lim_{M \to \infty} P \left( \sup_{N \leq n \leq M} |S_n - S_N| \geq \epsilon \right) \leq \lim_{M \to \infty} \frac{V(S_M - S_N)}{\epsilon^2} = \frac{1}{\epsilon^2} \sum_{n=N}^{\infty} V(X_n).$$

Therefore also

$$P \left( \bigcap_{N \geq 1} \left\{ \sup_{n \geq N} |S_n - S_N| \geq \epsilon \right\} \right) \leq \inf_{N \geq 1} P \left( \sup_{n \geq N} |S_n - S_N| \geq \epsilon \right) \leq \inf_{N \geq 1} \frac{1}{\epsilon^2} \sum_{n=N}^{\infty} V(X_n) = 0,$$

because of our assumption that the sum of the variances converges. Finally, this is true for all $\epsilon > 0$, so by the usual trick of replacing an uncountably-infinite intersection by a countable one (provided that the particular form of the event in question warrants this!), we get the claim that

$$P \left( \sum_{n=1}^{\infty} X_n \text{ does not converge} \right) = 0.$$

One could ask whether the sufficient condition given by the theorem above is also necessary (it is). More generally, what happens for random variables with non-zero expectations? What happens for r.v.’s with infinite expectations, or infinite variances? Kolmogorov formulated a general theorem that gives a necessary and sufficient condition for a series of independent random variables to converge almost surely.

**Theorem 9.6 (The Kolmogorov three-series theorem).** If $X_1, X_2, \ldots$ is a sequence of independent random variables, then the random series $\sum_{n=1}^{\infty} X_n$ converges almost surely if and only if the following three conditions hold:

1. $\sum_{n=1}^{\infty} P(|X_n| > 1) < \infty.$
2. The series $\sum_{n=1}^{\infty} E(X_n 1_{\{|X_n| \leq 1\}})$ converges.
3. $\sum_{n=1}^{\infty} V(X_n 1_{\{|X_n| \leq 1\}}) < \infty.$
If one of the conditions does not hold, then series $\sum X_n$ diverges almost surely.

We postpone the proof of Theorem 9.6 until later; we will prove it in Section 14.2 as an application of a generalized version of the central limit theorem. Note that since the convergence of the series $\sum X_n$ is equivalent to the convergence of $\sum aX_n$ for any constant $a$, the value 1 chosen for the truncation of $X_n$ in the theorem is arbitrary and can be replaced by any other constant.

**Example 9.7.** Let $(c_n)_{n=1}^\infty$ be a sequence of real numbers. Consider the series with random signs associated with the sequence $(c_n)$, which we denote $\sum_{n=1}^\infty \pm c_n$, and which more precisely represents the series
$$\sum_{n=1}^\infty c_n X_n,$$
where $X_1, X_2, \ldots$ is a sequence of i.i.d. r.v.’s taking the values $-1, +1$ with respective probabilities $1/2, 1/2$. By Theorem 9.5 it follows that if $\sum_{n=1}^\infty c_n^2 < \infty$ then the series $\sum_{n=1}^\infty \pm c_n$ converges almost surely. From Theorem 9.6, one can check easily that this condition is also necessary, in other words that the series with random series converges a.s. if and only if the series of squares $\sum c_n^2$ converges. Thus, for example, the harmonic series with random signs $\sum \pm \frac{1}{n}$ converges a.s., but the analogous series of square root reciprocals $\sum \pm \frac{1}{\sqrt{n}}$ diverges a.s. Compare this to the series with alternating signs $\sum \frac{(-1)^n}{n}$ and $\sum \frac{(-1)^n}{\sqrt{n}}$, both of which are known to converge! Try to develop your intuition by thinking about the reasons why the behavior for series with alternating signs and that for random signs is not the same.

**End of Part II**
Chapter 10: Stirling’s formula and the de Moivre-Laplace theorem

We start with a motivating example that was also historically the first instance in which the phenomenon that came to be known as the Central Limit Theorem was observed. Let $X_1, X_2, \ldots$ be an i.i.d. of $\text{Binom}(1, p)$ random variables, and let $S_n = \sum_{k=1}^{n} X_k$, a r.v. with distribution $\text{Binom}(n, p)$.

**Theorem 10.1** (The de Moivre-Laplace theorem). For any $t \in \mathbb{R}$,

$$
\Pr \left( \frac{S_n - np}{\sqrt{np(1-p)}} \leq t \right) \xrightarrow{n \to \infty} \Phi(t) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{t} e^{-x^2/2} \, dx.
$$

Since this is such a concrete example, the proof will simply require us to estimate a sum of the form $\sum_{0 \leq k \leq t} (\binom{n}{k})p^k(1-p)^{n-k}$. Knowing how to estimate such sums is a useful skill in its own right. Since the binomial coefficients are involved, we also need some preparation related to Stirling’s formula.

**Lemma 10.2.** The limit $C = \lim_{n \to \infty} \frac{n!}{\sqrt{n(n/e)^n}}$ exists.

**Proof.**

\[
\log n! = \sum_{k=1}^{n} \log k = \sum_{k=1}^{n} \int_{1}^{k} \frac{dx}{x} = \int_{1}^{n} \frac{n - \lfloor x \rfloor}{x} \, dx \\
= \int_{1}^{n} \frac{n + \frac{1}{2} + (\{x\} - \frac{1}{2}) - x}{x} \, dx = (n + 1/2) \log n - n + 1 + \int_{1}^{n} \frac{\{x\} - \frac{1}{2}}{x} \, dx \\
= (n + 1/2) \log n - n + 1 + \int_{1}^{\infty} \frac{\{x\} - \frac{1}{2}}{x} \, dx + o(1),
\]

where the last integral converges because $\int_{1}^{\infty} (\{x\} - \frac{1}{2}) \, dx$ is bounded and $1/x$ goes to $0$ as $x \to \infty$. \(\square\)

Note that an easy consequence of Lemma 10.2 is that $\binom{2n}{n} = (1 + o(1))2^{2n}/C\sqrt{n/2}$. We shall now use this to find the value of $C$. 

61
Lemma 10.3. Let \( f : \mathbb{R} \to \mathbb{R} \) be an \( n+1 \) times continuously-differentiable function. Then for all \( x \in \mathbb{R} \), we have

\[
f(x) = f(0) + f'(0)x + \frac{f''(0)}{2}x^2 + \ldots + \frac{f^{(n)}(0)}{n!}x^n + R_n(x),
\]

where

\[
R_n(x) = \frac{1}{n!} \int_0^x f^{(n+1)}(t)(x-t)^n \, dt.
\]

Proof. This follows by induction on \( n \), using integration by parts.

Lemma 10.4. \( C = \sqrt{2\pi} \).

Proof. Apply Lemma 10.3 with \( f(x) = (1 + x)^{2n+1} \) to compute \( R_n(1) \):

\[
\frac{1}{2^{2n+1}} R_n(1) = \frac{1}{2^{2n+1}} \cdot \frac{1}{n!} \int_0^1 (2n+1)(2n) \cdots (n+1)(1+t)(1-t)^n \, dt
\]

\[
= \frac{2(2n)}{2^{2n+1}} \left( n + \frac{1}{2} \right) \int_0^1 (1-t^2)^n \, dt = \frac{(2n)\sqrt{n}}{2^{2n}} (1 + \frac{1}{2n}) \int_0^{\sqrt{n}} \left( 1 - \frac{u^2}{n} \right)^n \, du
\]

\[
\xrightarrow{n \to \infty} \frac{\sqrt{2}}{C} \int_0^\infty e^{-u^2} \, du = \frac{\sqrt{2}}{C} \cdot \frac{\sqrt{\pi}}{2}.
\]

The convergence of the integrals is justified by the fact that \( (1 - u^2/n)^n \leq e^{-u^2} \) for all \( 0 \leq u \leq \sqrt{n} \), and \( (1 - u^2/n)^n \to e^{-u^2} \) as \( n \to \infty \), uniformly on compact intervals. To finish the proof, note that

\[
\frac{1}{2^{2n+1}} R_n(1) = \sum_{n<k \leq 2n+1} \frac{(2n+1)}{2^{2n+1}} = \frac{1}{2}
\]

(this is the probability that a Binom(2n + 1, 1/2) random variable takes a value \( > n \)). Therefore \( C = \sqrt{2\pi} \), as claimed.

Corollary 10.5 (Stirling’s formula). \( \lim_{n \to \infty} \frac{n!}{\sqrt{2\pi n (n/e)^n}} = 1. \)

Note that the proof is based on computing \( \mathbb{P}(S_{2n+1} > n) \) in two different ways, when \( S_{2n+1} \sim \text{Binom}(2n+1, 1/2) \). This is just the special case \( p = 1/2, t = 0 \) of Theorem 10.1! In this very special case, by symmetry the probability is equal to 1/2; on the other hand, Lemma 10.3 enables us to relate this to the asymptotic behavior of \( n! \) and to (half of) the gaussian integral \( \int_{-\infty}^{\infty} e^{-x^2} \, dx \). The evaluation of the constant \( C \) in Stirling’s formula is the
part that is attributed to James Stirling. The form that appears in Lemma 10.2 is due to Abraham de Moivre (1733).

With this preparation, it is now possible to apply the same technique to prove Theorem 10.1. Instead of the function \( f(x) = (1+x)^{2n+1} \), take the function \( g(x) = (1-p+x)^n \sum_{k=0}^{n} \binom{n}{k}p^k(1-p)^{n-k}x^k \), and compute the remainder \( R_k(1) \) of the Taylor expansion of \( g \), where \( k \approx np + t\sqrt{np}(1-p) \). This should converge to \( 1 - \Phi(t) \), and indeed, this follows without too much difficulty from Lemma 10.3. The computation is left as an exercise. We also sketch another way of proving Theorem 10.1 by directly approximating the probabilities \( \binom{n}{k}p^k(1-p)^{n-k} \) by Gaussian densities.

**Sketch of Proof of Theorem 10.1.** Denote \( q = 1-p \). For a large \( n \), let \( k \) be approximately equal to \( np + t\sqrt{npq} \), and use Stirling’s formula to estimate the probability \( P(S_n = k) \), as follows:

\[
P(S_n = k) = \binom{n}{k}p^kq^{n-k} = (1 + o(1)) \frac{\sqrt{2\pi n}(n/e)^n p^k q^{n-k}}{\sqrt{2\pi k(k/e)^k} \sqrt{2\pi(n-k)((n-k)/e)^{n-k}}}
\]

\[
= \frac{1 + o(1)}{\sqrt{2\pi npq}} \left( \frac{np}{k} \right)^k \left( \frac{nq}{n-k} \right)^{n-k}
\]

\[
= \frac{1 + o(1)}{\sqrt{2\pi npq}} \left( 1 + \frac{t\sqrt{q}}{\sqrt{np}} \right)^{-k} \left( 1 - \frac{t\sqrt{p}}{\sqrt{np}} \right)^{-(n-k)}.
\]

Taking the logarithm of the product of the last two factors, using the facts that \( k \approx np + t\sqrt{npq} \), \( n-k \approx nq - t\sqrt{npq} \), and that \( \log(1+x) = x - x^2/2 + O(x^3) \) when \( x \to 0 \), we see that

\[
\log \left[ \left( 1 + \frac{t\sqrt{q}}{\sqrt{np}} \right)^{-k} \left( 1 - \frac{t\sqrt{p}}{\sqrt{np}} \right)^{-(n-k)} \right]
\]

\[
= -(np + t\sqrt{npq}) \log \left( 1 + \frac{t\sqrt{q}}{\sqrt{np}} \right) - (nq - t\sqrt{npq}) \log \left( 1 - \frac{t\sqrt{p}}{nq} \right)
\]

\[
= -(np + t\sqrt{npq}) \left( \frac{t\sqrt{q}}{\sqrt{np}} - \frac{t^2q}{2np} \right) - (nq - t\sqrt{npq}) \left( -\frac{t\sqrt{p}}{\sqrt{npq}} - \frac{t^2p}{2np} \right) + O \left( \frac{t^3}{\sqrt{n}} \right)
\]

\[
= -t\sqrt{npq} - t^2q + t^2q - t\sqrt{npq} - t^2p + \frac{t^2p}{2} + O \left( \frac{t^3}{\sqrt{n}} \right)
\]

\[
= -\frac{t^2}{2} + O \left( \frac{t^3}{\sqrt{n}} \right).
\]
It follows that
\[ P(S_n = k) = \frac{1 + o(1)}{\sqrt{2\pi npq}} e^{-t^2/2} \]
In other words, the individual probabilities for \( S_n \) approximate a normal density! From here, it is not too hard to show that the probability
\[ P \left( a \leq \frac{S_n - np}{\sqrt{npq}} \leq b \right) = \sum_{np + a\sqrt{npq} \leq k \leq np + b\sqrt{npq}} P(S_n = k) \]
is approximately a Riemann sum for the integral \((2\pi)^{-1/2} \int_a^b e^{-x^2/2} dx = \Phi(b) - \Phi(a)\). In fact, this is true since for \(a, b\) fixed and \(k\) ranging between \(np + a\sqrt{npq}\) and \(np + b\sqrt{npq}\), the error concealed by the \(o(1)\) term is uniformly small (smaller than any \(\epsilon > 0\), say, when \(n\) is sufficiently large), since this error term originates with three applications of Stirling’s approximation formula (for \(n!\), for \(k!\) and for \((n - k)!\)) followed by the log function second-order Taylor expansion above.

One lesson that can be learned from this proof is that doing computations for specific distributions can be messy! So we might be better off looking for more general, and therefore more conceptual, techniques for proving convergence to the normal distribution, that require less explicit computations; fortunately such techniques exist, and will lead us to the much more general central limit theorem.
Chapter 11: Convergence in distribution

11.1 Definition

Since we will be talking about convergence of the distribution of random variables to the normal distribution, it makes sense to develop the general theory of convergence of distributions to a limiting distribution.

**Definition 11.1.** Let \((F_n)_{n=1}^{\infty}\) be a sequence of distribution functions. We say that \(F_n\) converges to a limiting distribution function \(F\), and denote this by \(F_n \Rightarrow F\), if \(F_n(x) \to F(x)\) as \(n \to \infty\) for any \(x \in \mathbb{R}\) which is a continuity point of \(F\). If \(X, (X_n)_{n=1}^{\infty}\) are random variables, we say that \(X_n\) converges in distribution to \(X\) (or, interchangeably, converges in distribution to \(F_X\)) if \(F_{X_n} \Rightarrow F_X\).

This definition, which may seem unnatural at first sight, will become more reasonable after we prove the following lemma.

**Lemma 11.2.** The following are equivalent:

1. \(X_n \Rightarrow X\).

2. \(\mathbb{E}f(X_n) \to \mathbb{E}f(X)\) for any bounded continuous function \(f : \mathbb{R} \to \mathbb{R}\).

3. There exists a r.v. \(Y\) and a sequence \((Y_n)_{n=1}^{\infty}\) of r.v.’s, all defined on some probability space \((\Omega, \mathcal{F}, \mathbb{P})\) such that \(Y_n \to Y\) a.s., \(Y\) is equal in distribution to \(X\), and each \(Y_n\) is equal in distribution to the respective \(X_n\).

**Proof.** Proof that 2 \(\Rightarrow\) 1: Assume that \(\mathbb{E}f(X_n) \to \mathbb{E}f(X)\) for any bounded continuous function \(f : \mathbb{R} \to \mathbb{R}\), and fix \(x \in \mathbb{R}\). For any \(t \in \mathbb{R}\) and \(\epsilon > 0\), define a function \(g_{t,\epsilon} : \mathbb{R} \to \mathbb{R}\) by

\[
g_{t,\epsilon}(u) = \begin{cases} 1 & u < t, \\ \frac{t-u+\epsilon}{\epsilon} & u \leq t \leq t+\epsilon, \\ 0 & u > t+\epsilon. \end{cases}
\]

Then we have that

\[
\mathbb{E}(g_{x-\epsilon,\epsilon}(X_n)) \leq F_{X_n}(x) = \mathbb{E}(1_{(-\infty,x]}(X_n)) \leq \mathbb{E}(g_{x,\epsilon}(X_n))
\]
Letting $n \to \infty$ gives the chain of inequalities

$$F_X(x - \epsilon) \leq \mathbb{E}(g_{x-\epsilon}(X)) \leq \liminf_{n \to \infty} F_{X_n}(x) \leq \limsup_{n \to \infty} F_{X_n}(x) \leq \mathbb{E}(g_{x,\epsilon}(X)) \leq F_X(x + \epsilon).$$

Now if $x$ is a point of continuity of $F_X$, letting $\epsilon \downarrow 0$ gives that $\lim_{n \to \infty} F_{X_n}(x) = F_X(x)$.

Proof that $3 \implies 2$: this follows immediately by applying the bounded convergence theorem to the sequence $g(Y_n)$.

Proof that $1 \implies 3$: Take $(\Omega, \mathcal{F}, P) = ((0,1), \mathcal{B}(0,1), \text{Leb})$. For each $n \geq 1$, let $Y_n(x) = \sup\{y : F_{X_n}(y) < x\}$ be the lower quantile function of $X_n$, as discussed in a previous lecture, and similarly let $Y(x) = \sup\{y : F_X(y) < x\}$ be the lower quantile function of $X$. Then as we previously showed, we have $F_Y \equiv F_X$ and $F_{Y_n} \equiv F_{X_n}$ for all $n$. It remains to show that $Y_n(x) \to Y(x)$ for almost all $x \in (0,1)$. In fact, we show that this is true for all but a countable set of $x$’s. Denote $Y^*(x) = \inf\{y : F_X(y) > x\}$ (the upper quantile function of $X$). As we have seen, we always have $Y(x) \leq Y^*(x)$, and $Y(x) = Y^*(x)$ for all $x \in (0,1)$ except on a countable set of $x$’s (the exceptional $x$’s correspond to intervals where $F_X$ is constant; these intervals are disjoint and each one contains a rational point).

Let $x \in (0,1)$ be such that $Y(x) = Y^*(x)$. This means that for any $y < Y(x)$ we have $F_X(y) < x$, and for any $z > Y(x)$ we have $F_X(z) > x$. Now, take a $y < Y(x)$ which is a continuity point of $F_X$. Then $F_{X_n}(y) \to F_X(y)$ as $n \to \infty$, so also $F_{X_n}(y) < x$ for sufficiently large $n$, which means (by the definition of $Y_n$) that $Y_n(x) \geq y$ for such large $n$. This establishes that $\liminf_{n \to \infty} Y_n(x) \geq Y(x)$, since we have continuity points $y < Y(x)$ that are arbitrarily close to $Y(x)$.

Similarly, take a $z > Y(x)$ which is a continuity point of $F_X$. Then $F_{X_n}(z) \to F_X(z)$ as $n \to \infty$, so also $F_{X_n}(z) > x$ for large $n$, which implies that $Y_n(x) \leq z$. Again, by taking continuity points $z > Y(x)$ that are arbitrarily close to $Y(x)$ we get that $\limsup_{n \to \infty} Y_n(x) \leq Y(x)$. Combining these last two results shows that $Y_n(x) \to Y(x)$ which was what we wanted.

\[ \square \]

11.2 Examples

1. Normal convergence: We showed that if $X_1, X_2, \ldots$ are i.i.d. Binom$(1, p)$ r.v.’s and $S_n = \sum_{k=1}^n X_k$, then

$$\frac{S_n - n\mathbb{E}(X_1)}{\sqrt{n\sigma(X_1)}} \implies N(0, 1).$$
Similarly, using explicit computations (see the homework) it is not too difficult to see that this is also true when $X_1 \sim \text{Poisson}(1)$, $X_1 \sim \text{Exp}(1)$, and in other specific examples. The central limit theorem generalizes this claim to any i.i.d. sequence with finite variance.

2. **Waiting for rare events:** If for each $0 < p < 1$ we have a r.v. $X_p \sim \text{Geom}_0(p)$, then $\Pr(X_p \geq n) = (1 - p)^{n-1}$. It follows that

$$
\Pr(pX_p > x) = (1 - p)^{\lfloor x/p \rfloor} \to e^{-x}, \quad (x > 0),
$$

so

$$
pX_p \to \text{Exp}(1) \quad \text{as } p \downarrow 0.
$$

3. **Pólya’s urn:** Let $X_n$ be the number of white balls in the Pólya urn experiment after starting with one white ball and one black ball and performing the experiment for $n$ steps (so that there are $n+2$ balls). In a homework exercise we showed that $X_n$ is a discrete uniform r.v. on $\{1, 2, \ldots, n+1\}$. It follows easily that the proportion of white balls in the urn converges in distribution:

$$
\frac{X_n}{n+2} \to U(0, 1).
$$

4. **Gumbel distribution:** If $X_1, X_2, \ldots$ are i.i.d. $\text{Exp}(1)$ random variables, and $M_n = \max(X_1, \ldots, X_n)$, we showed in a homework exercise that

$$
\Pr(M_n - \log n \leq x) \to e^{-e^{-x}}, \quad x \to \infty
$$

It follows that

$$
M_n - \log n \to F
$$

where $F(x) = \exp(-e^{-x})$ is called the Gumbel distribution.

### 11.3 Compactness and tightness

**Theorem 11.3** (Helly’s selection theorem). If $(F_n)_{n=1}^{\infty}$ is a sequence of distribution functions, then there is a subsequence $F_{n_k}$ and a right-continuous, nondecreasing function $H : \mathbb{R} \to [0, 1]$ such that

$$
F_{n_k}(x) \to H(x)
$$

holds for any $x \in \mathbb{R}$ which is a continuity point of $H$. 67
Note. The subsequential limit $H$ need not be a distribution function, since it may not satisfy the properties $\lim_{x \to -\infty} H(x) = 0$ or $\lim_{x \to \infty} H(x) = 1$. For example, taking $F_n = F_{X_n}$, where $X_n \sim U[-n,n]$, we see that $F_n(x) \to 1/2$ for all $x \in \mathbb{R}$. For a more interesting example, take $G_n = (F_n + F_{Z_n})/2$ where $F_n$ are as in the previous example, and $Z_n$ is some sequence of r.v.’s that converges in distribution.

Proof. First, note that we can find a subsequence $(n_k)_{k=1}^{\infty}$ such that $F_{n_k}(r)$ converges to a limit $G(r)$ at least for any rational number $r$. This is done by combining the compactness of the interval $[0, 1]$ (which implies that for any specific $a \in \mathbb{R}$ we can always take a subsequence to make the sequence of numbers $F_n(a)$ converge to a limit) with a diagonal argument (for some enumeration $r_1, r_2, r_3, \ldots$ of the rationals, first take a subsequence to force convergence at $r_1$; then take a subsequence of that subsequence to force convergence at $r_2$, etc.; now form a subsequence whose $k$-th term is the $k$-th term of the $k$-th subsequence in this series).

Now, use $G(\cdot)$, which is defined only on the rationals and not necessarily right-continuous (but is nondecreasing), to define a function $H : \mathbb{R} \to \mathbb{R}$ by

$$H(x) = \inf\{G(r) : r \in \mathbb{Q}, r > x\}.$$ 

This function is clearly nondecreasing, and is also right-continuous, since we have

$$\lim_{x_n \uparrow x} H(x_n) = \inf\{G(r) : r \in \mathbb{Q}, r > x_n \text{ for some } n\} = \inf\{G(r) : r \in \mathbb{Q}, r > x\} = H(x).$$

Finally, let $x$ be a continuity point of $H$. To show that $F_{n_k}(x) \to H(x)$, fix some $\epsilon > 0$ and let $r_1, r_2, s$ be rationals such that $r_1 < r_2 < x < s$ and

$$H(x) - \epsilon < H(r_1) \leq H(r_2) \leq H(x) \leq H(s) < H(x) + \epsilon.$$ 

Then since $F_{n_k}(r_2) \to G(r_2) \geq H(r_1)$, and $F_{n_k}(s) \to G(s) \leq H(s)$, it follows that for sufficiently large $k$ we have

$$H(x) - \epsilon < F_{n_k}(r_2) \leq F_{n_k}(x) \leq F_{n_k}(s) < H(x) + \epsilon.$$ 

Therefore

$$H(x) - \epsilon < \liminf_{n \to \infty} F_{n_k}(x) \leq \limsup_{n \to \infty} F_{n_k}(x) \leq H(x) + \epsilon,$$

and since $\epsilon$ was arbitrary this proves the claim. \qed
Theorem 11.3 can be thought of as a kind of compactness property for probability distributions, except that the subsequential limit guaranteed to exist by the theorem is not a distribution function. To ensure that we get a distribution function, it turns out that a certain property called tightness has to hold.

**Definition 11.4.** A sequence \((\mu_n)_{n=1}^\infty\) of probability measures on \((\mathbb{R}, B)\) is called tight if for any \(\epsilon > 0\) there exists an \(M > 0\) such that

\[
\liminf_{n \to \infty} \mu_n([-M, M]) \geq 1 - \epsilon.
\]

A sequence of distribution functions \((F_n)_{n=1}^\infty\) is called tight if the associated probability measures determined by \(F_n\) form a tight sequence, or, more explicitly, if for any \(\epsilon > 0\) there exists an \(M > 0\) such that

\[
\limsup_{n \to \infty} (1 - F_n(M) + F_n(-M)) < \epsilon.
\]

A sequence of random variables is called tight if the sequence of their distribution functions is tight.

**Theorem 11.5.** If \((F_n)_{n=1}^\infty\) is a tight sequence of distribution functions, then there exists a subsequence \((F_{n_k})_{k=1}^\infty\) and a distribution function \(F\) such that \(F_{n_k} \Rightarrow F\). In fact, any subsequential limit \(H\) as guaranteed to exist in the previous theorem is a distribution function.

**Exercise 11.6.** Prove that the converse is also true, i.e., if a sequence is not tight then it must have at least one subsequential limit \(H\) (in the sense of the subsequence converging to \(H\) at any continuity point of \(H\)) that is not a proper distribution function. In particular, it is worth noting that a sequence that converges in distribution is tight.

**Proof.** Let \(H\) be a nondecreasing, right-continuous function that arises as a subsequential limit-in-distribution of a subsequence \(F_{n_k}\), that we know exists by Theorem 11.3. To show that \(H\) is a distribution function, fix \(\epsilon > 0\), and let \(M > 0\) be the constant guaranteed to exist in the definition of tightness. Let \(x < -M\) be a continuity point of \(H\). We have

\[
H(x) = \lim_{k \to \infty} F_{n_k}(x) \leq \limsup_{k \to \infty} F_{n_k}(-M) \leq \limsup_{k \to \infty} (F_{n_k}(-M) + (1 - F_{n_k}(M))) < \epsilon,
\]

so this shows that \(\lim_{x \to -\infty} H(x) = 0\). Similarly, let \(x > M\) be a continuity point of \(H\). Then

\[
H(x) = \lim_{k \to \infty} F_{n_k}(x) \geq \liminf_{k \to \infty} F_{n_k}(M) \geq \liminf_{k \to \infty} (F_{n_k}(M) - F_{n_k}(-M)) > 1 - \epsilon,
\]

which shows that \(\lim_{x \to \infty} H(x) = 1\). \(\Box\)
The condition of tightness is not very restrictive, and in practical situations it is usually quite easy to verify. The following lemma gives an example that is relevant for our purposes.

**Lemma 11.7.** If $X_1, X_2, \ldots$ are r.v.’s such that $\mathbb{E}X_n = 0$ and $\mathbb{V}(X_n) < C$ for all $n$, then $(X_n)_n$ is a tight sequence.

**Proof.** Use Chebyshev’s inequality:

$$\mathbb{P}(|X_n| > M) \leq \frac{\mathbb{V}(X_n)}{M^2} \leq \frac{C}{M^2},$$

so, if $\epsilon > 0$ is given, taking $M = \sqrt{C/\epsilon}$ ensures that the left-hand side is bounded by $\epsilon$. \qed
Chapter 12: Characteristic functions

12.1 Definition and basic properties

A main tool in our proof of the central limit theorem will be that of characteristic functions. The basic idea will be to show that

\[ \mathbb{E} \left[ g \left( \frac{S_n - n \mu}{\sqrt{n \sigma}} \right) \right] \xrightarrow{n \to \infty} \mathbb{E} g(N(0,1)) \]

for a sufficiently large family of functions \( g \). It turns out that the family of functions of the form

\[ g_t(x) = e^{itx}, \quad (t \in \mathbb{R}), \]

is ideally suited for this purpose. (Here and throughout, \( i = \sqrt{-1} \)).

Definition 12.1. The characteristic function of a r.v. \( X \), denoted \( \varphi_X \), is defined by

\[ \varphi_X(t) = \mathbb{E} \left( e^{itX} \right) = \mathbb{E}(\cos(tX)) + i\mathbb{E}(\sin(tX)), \quad (t \in \mathbb{R}). \]

Note that we are taking the expectation of a complex-valued random variable (which is a kind of two-dimensional random vector, really). However, the main properties of the expectation operator (linearity, the triangle inequality etc.) that hold for real-valued random variables also hold for complex-valued ones, so this will not pose too much of a problem.

Here are some simple properties of characteristic functions. For simplicity we denote \( \varphi = \varphi_X \) where there is no risk of confusion.

1. \( \varphi(0) = \mathbb{E}e^{i0\cdot X} = 1. \)

2. \( \varphi(-t) = \mathbb{E}e^{-itX} = \overline{\mathbb{E}(e^{itX})} = \overline{\varphi(t)} \) (where \( \overline{z} \) denotes the complex conjugate of a complex number \( z \)).

3. \( |\varphi(t)| \leq \mathbb{E} |e^{itX}| = 1 \) by the triangle inequality.

4. \( |\varphi(t) - \varphi(s)| \leq \mathbb{E} |e^{itX} - e^{isX}| = \mathbb{E} |e^{isX} (e^{i(t-s)X} - 1)| = \mathbb{E} |e^{i(t-s)X} - 1|. \) Note also that \( \mathbb{E} |e^{iuX} - 1| \to 0 \) as \( u \downarrow 0 \) by the bounded convergence theorem. It follows that \( \varphi \) is a uniformly continuous function on \( \mathbb{R} \).

5. \( \varphi_{aX}(t) = \mathbb{E}e^{iatX} = \varphi_X(at), \quad (a \in \mathbb{R}). \)
6. $\varphi_{X+b}(t) = Ee^{it(X+b)} = e^{ibt}\varphi_X(t), \ (b \in \mathbb{R})$.

7. **Important:** If $X, Y$ are independent then

$$
\varphi_{X+Y}(t) = E(e^{it(X+Y)}) = E(e^{itX})E(e^{itY}) = \varphi_X(t)\varphi_Y(t).
$$

Note that this is the main reason why characteristic functions are such a useful tool for studying the distribution of a sum of independent random variables.

A **note on terminology.** If $X$ has a density function $f$, then the characteristic function can be computed as

$$
\varphi_X(t) = \int_{-\infty}^{\infty} f_X(x)e^{itx} \, dx.
$$

In all other branches of mathematics, this would be called the **Fourier transform** of $f$. So the concept of a characteristic function generalizes the Fourier transform. If $\mu$ is the distribution measure of $X$, some authors write

$$
\varphi_X(t) = \int_{-\infty}^{\infty} e^{itx}d\mu(x)
$$

(which is an example of a **Lebesgue-Stieltjes integral**) and call this the **Fourier-Stieltjes transform** (or just the Fourier transform) of the measure $\mu$.

### 12.2 Examples

No study of characteristic functions is complete without “dirtying your hands” a little to compute the characteristic function for some important cases. The following exercise is highly recommended

**Exercise 12.2.** Compute the characteristic functions for the following distributions.

1. **Coin flips:** Compute $\varphi_X$ when $P(X = -1) = P(X = 1) = 1/2$ (this comes out slightly more symmetrical than the usual Bernoulli r.v. for which $P(X = 0) = P(X = 1) = 1/2$).

\footnote{Well, more or less – it is really the inverse Fourier transform; but it will be the Fourier transform if we replace $t$ by $-t$, so that is almost the same thing}
2. **Symmetric random walk:** Compute \( \varphi_{S_n} \) where \( S_n = \sum_{k=1}^{n} X_k \) is the sum of \( n \) i.i.d. copies of the coin flip distribution above.

3. **Poisson distribution:** \( X \sim \text{Poisson}(\lambda) \).

4. **Uniform distribution:** \( X \sim U[a,b] \), and in particular \( X \sim [-1,1] \) which is especially symmetric and useful in applications.

5. **Exponential distribution:** \( X \sim \text{Exp}(\lambda) \).

6. **Symmetrized exponential:** A r.v. \( Z \) with density function \( f_Z(x) = e^{-|x|} \). Note that this is the distribution of the exponential distribution after being “symmetrized” in either of two ways: (i) We showed that if \( X, Y \sim \text{Exp}(1) \) are independent then \( X - Y \) has density \( e^{-|x|} \); (ii) alternatively, it is the distribution of an “exponential variable with random sign”, namely \( \varepsilon \cdot X \) where \( X \sim \text{Exp}(1) \) and \( \varepsilon \) is a random sign (same as the coin flip distribution mentioned above) that is independent of \( X \).

The normal distribution has the nice property that its characteristic function is equal, up to a constant, to its density function.

**Lemma 12.3.** If \( Z \sim N(0,1) \) then

\[
\varphi_Z(t) = e^{-t^2/2}.
\]

**Proof.**

\[
\varphi_Z(t) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{itx} e^{-x^2/2} dx = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-t^2/2} e^{(x-it)^2/2} dx = e^{-t^2/2} \left( \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{(x-it)^2/2} dx \right).
\]

As Durrett suggests in his “physics proof” (p. 92 in [Dur2010], 91 in [Dur2004]), the expression in parentheses is 1, since it is the integral of a normal density with mean \( it \) and variance 1. This is a nonsensical argument, of course (\( it \) being an imaginary number), but the claim is true, easy and is proved in any complex analysis course using contour integration.

Alternatively, let \( S_n = \sum_{k=1}^{n} X_k \) where \( X_1, X_2, \ldots \) are i.i.d. coin flips with \( \text{P}(X_k) = -1 = \text{P}(X_k) = 1 = 1/2 \). We know from the de Moivre-Laplace theorem (Theorem 10.1) that

\[
S_n/\sqrt{n} \implies N(0,1),
\]

73
so that
\[
\varphi_{S_n/\sqrt{n}}(t) = \mathbb{E}\left(e^{itS_n/\sqrt{n}}\right) \xrightarrow{n \to \infty} \varphi_Z(t), \quad (t \in \mathbb{R}),
\]
since the function \(x \to e^{itx}\) is bounded and continuous. On the other hand, from the exercise above it is easy to compute that \(\varphi_{S_n}(t) = \cos^n(t)\), which implies that
\[
\varphi_{S_n/\sqrt{n}}(t) = \cos^n \left( \frac{t}{\sqrt{n}} \right) = \left( 1 - \frac{t^2}{2n} + O \left( \frac{t^4}{n^2} \right) \right)^n \xrightarrow{n \to \infty} e^{-t^2/2}.
\]

As a consequence, let \(X \sim N(0, \sigma_1^2)\) and \(Y \sim N(0, \sigma_2^2)\) be independent, and let \(Z = X+Y\). Then
\[
\varphi_X(t) = e^{-\sigma_1^2 t^2/2}, \quad \varphi_Y(t) = e^{-\sigma_2^2 t^2/2},
\]
so \(\varphi_Z(t) = e^{-(\sigma_1^2 + \sigma_2^2)/2}\). This is the same as \(\varphi_W(t)\), where \(W \sim N(0, \sigma_1^2 + \sigma_2^2)\). It would be nice if we could deduce from this that \(Z \sim N(0, \sigma_1^2 + \sigma_2^2)\) (we already proved this fact in a homework exercise, but it’s always nice to have several proofs of a result, especially an important one like this one). This naturally leads us to an important question about characteristic functions, which we consider in the next section.

### 12.3 The inversion formula

A fundamental question about characteristic functions is whether they contain all the information about a distribution, or in other words whether knowing the characteristic function determines the distribution uniquely. This question is answered (affirmatively) by the following theorem, which is a close cousin of the standard inversion formula from analysis for the Fourier transform.

**Theorem 12.4** (The inversion formula). If \(X\) is a r.v. with distribution \(\mu_X\), then for any \(a < b\) we have
\[
\lim_{T \to \infty} \frac{1}{2\pi} \int_{-T}^{T} \frac{e^{-iat} - e^{-ibt}}{it} \varphi_X(t) \, dt = \mu_X((a, b)) + \frac{1}{2} \mu_X(\{a, b\})
\]
\[
= P(a < X < b) + \frac{1}{2} P(X = a) + \frac{1}{2} P(X = b).
\]
Proof. Throughout the proof, denote $\varphi(t) = \varphi_X(t)$ and $\mu = \mu_X$. For convenience, we use the notation of Lebesgue-Stieltjes integration with respect to the measure $\mu$, remembering that this really means taking the expectation of some function of the r.v. $X$. Denote

$$I_T = \int_{-T}^{T} \frac{e^{-iat} - e^{-ibt}}{it} \varphi(t) \, dt = \int_{-T}^{T} \int_{-\infty}^{\infty} \frac{e^{-iat} - e^{-ibt}}{it} e^{itx} \, d\mu(x) \, dt. \quad (12)$$

Since $\frac{e^{-iat} - e^{-ibt}}{it}$ is a bounded function of $t$ (it is bounded in absolute value by $b - a$), it follows by Fubini’s theorem that we can change the order of integration, so

$$I_T = \int_{-\infty}^{\infty} \int_{-T}^{T} \frac{e^{-iat} - e^{-ibt}}{it} e^{itx} \, dt \, d\mu(x)
= \int_{-\infty}^{\infty} \left[ \int_{-T}^{T} \frac{\sin(t(x-a))}{t} \, dt - \int_{-T}^{T} \frac{\sin(t(x-b))}{t} \, dt \right] \, d\mu(x)
= \int_{-\infty}^{\infty} \left( R(x-a,T) - R(x-b,T) \right) \, d\mu(x),$$

where we denote $R(\theta,T) = \int_{-T}^{T} \sin(\theta t) \, dt$. Note that in the notation of expectations this can be written as $I_T = \mathbb{E}(R(X-a,T) - R(X-b,T))$. This can be simplified somewhat; in fact, observe also that

$$R(\theta, T) = 2 \text{sgn}(\theta) \int_{0}^{\pi \theta / T} \frac{\sin x}{x} \, dx = 2 \text{sgn}(\theta) S(|\theta|T),$$

where we denote $S(x) = \int_{0}^{x} \frac{\sin(u)}{u} \, du$ and $\text{sgn}(\theta)$ is 1 if $\theta > 0$, $-1$ if $\theta < 0$ and 0 if $\theta = 0$. By a standard convergence test for integrals, the improper integral $\int_{0}^{\infty} \frac{\sin u}{u} \, du = \lim_{x \to \infty} S(x)$ converges; denote its value by $C/4$. Thus, we have shown that $R(\theta, T) \to 2 \text{sgn}(\theta)C$ as $T \to \infty$, hence that

$$R(x-a, T) - R(x-b, T) \to \begin{cases} C & a < x < b, \\ C/2 & x = a \text{ or } x = b, \\ 0 & x < a \text{ or } x > b. \end{cases}$$

Furthermore, the function $R(x-a, T) - R(x-b, T)$ is bounded in absolute value by $2 \sup_{x \geq 0} S(x)$. It follows that we can apply the bounded convergence theorem in (12) to get that

$$I_T \to \begin{cases} \mathbb{E}(1_{a < X < b}) + (C/2) \mathbb{E}(1_{X = a}) + 1_{X = b}) = C\mu((a,b)) + (C/2)\mu\{a,b\}. \end{cases} \quad (13)$$
This is just what we claimed, minus the fact that \( C = 2\pi \). This fact is a well-known integral evaluation from complex analysis. We can also deduce it in a self-contained manner, by applying what we proved to a specific measure \( \mu \) and specific values of \( a \) and \( b \) for which we can evaluate the limit in (12) directly. This is not entirely easy to do, but one possibility, involving an additional limiting argument, is outlined in the next exercise; see also Exercise 1.7.5 on p. 35 in [Dur2010], (Exercise 6.6, p. 470 in Appendix A.6 of [Dur2004]) for a different approach to finding the value of \( C \).

Exercise 12.5. \((\text{Recommended for aspiring analysts...})\) For each \( \sigma > 0 \), let \( X_\sigma \) be a r.v. with distribution \( \text{N}(0, \sigma^2) \) and therefore with density \( f_{X}(x) = (\sqrt{2\pi}\sigma)^{-1}e^{-x^2/2\sigma^2} \) and characteristic function \( \varphi_{X}(t) = e^{-\sigma^2t^2/2} \). For fixed \( \sigma \), apply Theorem 12.4 in its weak form given by (13) (that is, without the knowledge of the value of \( C \)), with parameters \( X = X_\sigma \), \( a = -1 \) and \( b = 1 \), to deduce the identity

\[
\frac{C}{\sqrt{2\pi}\sigma} \int_{-1}^{1} e^{-x^2/2\sigma^2} \, dx = \int_{-\infty}^{\infty} \frac{2\sin t}{t} e^{-\sigma^2 t^2/2} \, dt.
\]

Now multiply both sides by \( \sigma \) and take the limit as \( \sigma \to \infty \). For the left-hand side this should give in the limit (why?) the value \( (2C)/\sqrt{2\pi} \). For the right-hand side this should give \( 2\sqrt{2\pi} \). Justify these claims and compare the two numbers to deduce that \( C = 2\pi \).

The following theorem shows that the inversion formula can be written as a simpler connection between the characteristic function and the density function of a random variable, in the case when the characteristic function is integrable.

Theorem 12.6. If \( \int_{-\infty}^{\infty} |\varphi_{X}(t)| \, dt < \infty \), then \( X \) has a bounded and continuous density function \( f_{X} \), and the density and characteristic function are related by

\[
\varphi_{X}(t) = \int_{-\infty}^{\infty} f_{X}(x)e^{itx} \, dx,
\]

\[
f_{X}(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \varphi_{X}(t)e^{-itx} \, dt.
\]

In the lingo of Fourier analysis, this is known as the \textbf{inversion formula for Fourier transforms}.

\textbf{Proof.} This is a straightforward corollary of Theorem 12.4. See p. 95 in either [Dur2010] or [Dur2004]. \qed
12.4 The continuity theorem

**Theorem 12.7.** Let \((X_n)_{n=1}^\infty\) be r.v.’s. Then:

(i) If \(X_n \xrightarrow{d} X\) for some r.v. \(X\), then \(\varphi_{X_n}(t) \to \varphi_X(t)\) for all \(t \in \mathbb{R}\).

(ii) If the limit \(\varphi(t) = \lim_{n \to \infty} \varphi_{X_n}(t)\) exists for all \(t \in \mathbb{R}\), and \(\varphi\) is continuous at 0, then \(\varphi \equiv \varphi_X\) for some r.v. \(X\), and \(X_n \xrightarrow{d} X\).

**Proof.** Part (i) follows immediately from the fact that convergence in distribution implies that \(Eg(X_n) \to Eg(X)\) for any bounded continuous function. It remains to prove the less trivial claim in part (ii). Assume that \(\varphi_{X_n}(t) \to \varphi(t)\) for all \(t \in \mathbb{R}\) and that \(\varphi\) is continuous at 0. First, we show that the sequence \((X_n)_{n=1}^\infty\) is tight. Fixing an \(M > 0\), we can bound the probability \(P(|X_n| > M)\), as follows:

\[
P(|X_n| > M) = E(1_{|X_n| > M}) \leq E\left[2 \left(1 - \frac{M}{2|X_n|}\right) 1_{|X_n| > M}\right] \leq E\left[2 \left(1 - \frac{\sin(2X_n/M)}{2X_n/M}\right) 1_{|X_n| > M}\right].
\]

But this last expression can be related to the behavior of the characteristic function near 0. Denote \(\delta = 2/M\). Reverting again to the Lebesgue-Stieltjes integral notation, we have

\[
E\left[2 \left(1 - \frac{\sin(2X_n/M)}{2X_n/M}\right) 1_{|X_n| > M}\right] = 2 \int_{|x| > 2/\delta} \left(1 - \frac{\sin(\delta x)}{\delta x}\right) d\mu_{X_n}(x)
\]

\[
\leq 2 \int_{-\infty}^{\infty} \left(1 - \frac{\sin(\delta x)}{\delta x}\right) d\mu_{X_n}(x) = \int_{-\infty}^{\infty} \frac{1}{\delta} \left(\int_{-\delta}^{\delta} (1 - e^{itx}) dt\right) d\mu_{X_n}(x).
\]

Now use Fubini’s theorem to get that this bound can be written as

\[
\frac{1}{\delta} \int_{-\delta}^{\delta} \int_{-\infty}^{\infty} (1 - e^{itx}) d\mu_{X_n}(x) dt = \frac{1}{\delta} \int_{-\delta}^{\delta} (1 - \varphi_{X_n}(t)) dt \xrightarrow{n \to \infty} \frac{1}{\delta} \int_{-\delta}^{\delta} (1 - \varphi(t)) dt
\]

(the convergence follows from the bounded convergence theorem). So we have shown that

\[
\limsup_{n \to \infty} P(|X_n| > M) \leq \frac{1}{\delta} \int_{-\delta}^{\delta} (1 - \varphi(t)) dt.
\]

But, because of the assumption that \(\varphi(t) \to \varphi(0) = 1\) as \(t \to 0\), it follows that if \(\delta\) is sufficiently small then \(\delta^{-1} \int_{-\delta}^{\delta} (1 - \varphi(t)) dt < \epsilon\), where \(\epsilon > 0\) is arbitrary; so this establishes the tightness claim.
Finally, to finish the proof, let \((n_k)_{k=1}^\infty\) be a subsequence (guaranteed to exist by tightness) such that \(X_{n_k} \Rightarrow Y\) for some r.v. \(Y\). Then \(\varphi_{X_{n_k}}(t) \to \varphi_Y(t) = \varphi(t)\) as \(k \to \infty\) for all \(t \in \mathbb{R}\), so \(\varphi \equiv \varphi_Y\). This determines the distribution of \(Y\), which means that the limit in distribution is the same no matter what convergent in distribution subsequence of the sequence \((X_n)_n\) we take. But this implies that \(X_n \Rightarrow Y\) (why? The reader is invited to verify this last claim; it is best to use the definition of convergence in distribution in terms of expectations of bounded continuous functions).

\[\square\]

12.5 Moments

The final step in our lengthy preparation for the proof of the central limit theorem will be to tie the behavior of the characteristic function \(\varphi_X(t)\) near \(t = 0\) to the moments of \(X\). Note that, computing formally without regards to rigor, we can write

\[
\varphi_X(t) = \mathbf{E}(e^{itX}) = \mathbf{E}\left[\sum_{n=0}^{\infty} \frac{i^n t^n X^n}{n!}\right] = \sum_{n=0}^{\infty} \frac{i^n \mathbf{E}X^n}{n!} t^n.
\]

So it appears that the moments of \(X\) appear as (roughly) the coefficients in the Taylor expansion of \(\varphi_X\) around \(t = 0\). However, for CLT we don’t want to assume anything beyond the existence of the second moment, so a (slightly) more delicate estimate is required.

**Lemma 12.8.** \(\left| e^{ix} - \sum_{m=0}^{n} \frac{(ix)^m}{m!} \right| \leq \min\left(\frac{|x|^{n+1}}{(n+1)!}, \frac{2|x|^n}{n!}\right)\).

**Proof.** Start with the identity

\[
R_n(x) := e^{ix} - \sum_{m=0}^{n} \frac{(ix)^m}{m!} = \frac{i^{n+1}}{n!} \int_0^x (x-s)^n e^{is} ds,
\]

which follows from Lemma 10.3 that we used in the proof of Stirling’s formula. Taking the absolute value and using the fact that \(|e^{is}| = 1\) gives

\[
|R_n(x)| \leq \frac{1}{n!} \int_0^x |x-s|^n ds = \frac{|x|^{n+1}}{n!}.
\]

(14)

To get a bound that is better-behaved for large \(x\), note that

\[
R_n(x) = R_{n-1}(x) - \frac{(ix)^n}{n!} = R_{n-1}(x) - \frac{i^n}{(n-1)!} \int_0^x (x-s)^{n-1} ds
\]

\[= \frac{i^n}{(n-1)!} \int_0^x (x-s)^{n-1}(e^{is} - 1) ds.
\]

78
So, since $|e^{is} - 1| \leq 2$, we get that

$$|R_n(x)| \leq \frac{2}{(n-1)!} \int_0^x |x - s|^{n-1} \, ds = \frac{2|x|^n}{(n-1)!}. \quad (15)$$

Combining (14) and (15) gives the claim.

Now let $X$ be a r.v. with $E|X|^n < \infty$. Letting $x = tX$ in Lemma 12.8, taking expectations and using the triangle inequality, we get that

$$\left| \varphi_X(t) - \sum_{m=0}^n \frac{i^m E X^m}{m!} t^m \right| \leq E \left[ \min \left( \frac{|t|^{n+1} |X|^{n+1}}{(n+1)!}, \frac{2|t|^n |X|^n}{n!} \right) \right]. \quad (16)$$

Note that in this minimum of two terms, when $t$ is very small the first term gives a better bound, but when taking expectations we need the second term to ensure that the expectation is finite if $X$ is only assumed to have a finite $n$-th moment.

**Theorem 12.9.** If $X$ is a r.v. with mean $\mu = E X$ and $V(X) < \infty$ then

$$\varphi_X(t) = 1 + i\mu t - \frac{EX^2}{2} t^2 + o(t^2) \quad \text{as } t \to 0.$$

**Proof.** By (16) above, we have

$$\frac{1}{t^2} \left| \varphi_X(t) - \left( 1 + i\mu t - \frac{EX^2}{2} t^2 \right) \right| \leq E \left[ \min \left( |t| \cdot |X|^3/6, |X|^2 \right) \right].$$

As $t \to 0$, the right-hand side converges to 0 by the dominated convergence theorem. \qed
Chapter 13: Central limit theorems

13.1 The case of i.i.d. r.v.’s

We are now ready to prove:

**Theorem 13.1** (The central limit theorem). Let $X_1, X_2, \ldots$ be an i.i.d. sequence of r.v.’s with finite variance. Denote $\mu = \mathbb{E}X_1$, $\sigma = \sigma(X_1)$ and $S_n = \sum_{k=0}^{n} X_k$. Then as $n \to \infty$ we have the convergence in distribution

$$\frac{S_n - n\mu}{\sqrt{n}\sigma} \Rightarrow N(0,1).$$

**Proof.** For convenience, denote $\hat{X}_k = (X_k - \mu)/\sigma$ and $\hat{S}_n = \sum_{k=0}^{n} \hat{X}_k$. Then

$$\varphi_{\hat{S}_n/\sqrt{n}}(t) = \varphi_{\hat{S}_n}(t/\sqrt{n}) = \prod_{k=1}^{n} \varphi_{\hat{X}_k}(t/\sqrt{n}) = \left(\varphi_{\hat{X}_1}(t/\sqrt{n})\right)^n.$$ 

Note that $\mathbb{E}\hat{X}_1 = 0$ and $\mathbb{V}(\hat{X}_1) = \mathbb{E}\hat{X}_1^2 = 1$. Therefore by Theorem 12.9, $\varphi_{\hat{X}_1}$ satisfies

$$\varphi_{\hat{X}_1}(u) = 1 - \frac{u^2}{2} + o(u^2)$$

as $u \to 0$. It follows that

$$\varphi_{\hat{S}_n/\sqrt{n}}(t) = \left(1 - \frac{t^2}{2n} + o\left(\frac{t^2}{n}\right)\right)^n \xrightarrow{n \to \infty} e^{-t^2/2}$$

for any $t \in \mathbb{R}$. Using the continuity theorem (Theorem 12.7) and our previous computations, it follows that $\hat{S}_n \Rightarrow N(0,1)$, as claimed.

13.2 Generalizations

The CLT can be generalized in many ways. None of the assumptions (independence, identical distributions, even finite variance) are entirely necessary. A central paradigm of probability theory is that any random quantity that arises as a sum of many small contributions that are either independent or not too strongly dependent, will converge to the normal distribution in some asymptotic limit. Thousands of examples exist, but there is no single all-encompassing theorem that includes all of them as a special case. Rather, probabilists have a toolbox of
tricks and techniques that they try to apply in order to prove normal convergence in any given situation. Characteristic functions are among the more useful techniques. Another important technique, the so-called **moment method**, involves the direct use of moments:

If we can show that \( E(W_n^k) \to E(Z^k) \), where \((W_n)_{n=1}^\infty\) is the (normalized) sequence being studied, and \( Z \sim N(0,1) \), then by Theorem 3.3.12 in [Dur2010] (p. 105) or Theorem (3.12) in [Dur2004] (p. 109), that implies that \( W_n \Rightarrow N(0,1) \).

We now discuss several examples of interesting generalizations of CLT.

### 13.2.1 Triangular arrays

**Theorem 13.2** (Lindeberg-Feller CLT for triangular arrays). Let \((X_{n,k})_{1 \leq k \leq n < \infty}\) be a triangular array of r.v.’s. Denote \( S_n = \sum_{k=1}^n X_{n,k} \) (the sum of the \( n \)-th row). Assume that:

1. For each \( n \), the r.v.’s \((X_{n,k})_{k=1}^n\) are independent.
2. \( E(X_{n,k}) = 0 \) for all \( n, k \).
3. \( V(S_n) = \sigma_n^2 \to \sigma^2 < \infty \) as \( n \to \infty \).
4. For all \( \epsilon > 0 \), \( \lim_{n \to \infty} \sum_{k=1}^n E\left(X_{n,k}^2 I(\{|X_{n,k}| > \epsilon\})\right) = 0 \).

Then \( S_n \Rightarrow N(0,\sigma^2) \) as \( n \to \infty \).

**Proof.** See [Dur2010], p. 110–111 or [Dur2004], p. 115–116. The proof uses the characteristic function technique and is a straightforward extension of the proof for the i.i.d. case. \(\square\)

**Example 13.3.** (Record times and cycles in permutations). Let \( X_1, X_2, \ldots \) be i.i.d. \( U(0,1) \) r.v.’s. Let \( A_n \) be the event that \( \{X_n = \max(X_1, \ldots, X_n)\} \) (in this case, we say that \( n \) is a record time). Let \( S_n = \sum_{k=1}^n 1_{A_k} \) be the number of record times up to time \( n \). We saw in a homework exercise that the \( A_k \)'s are independent events and \( P(A_k) = 1/k \). This implies that \( E(S_n) = \sum_{k=1}^n \frac{1}{k} = H_n \) (the \( n \)-th harmonic number) and \( V(S_n) = \sum_{k=1}^n \frac{k-1}{k^2} \). Note that both \( E(S_n) \) and \( V(S_n) \) are approximately equal to \( \log n \), with an error term that is \( O(1) \). Now taking \( X_{n,k} = (1_{A_k} - k^{-1})/\sqrt{V(S_n)} \) in Theorem 13.2, it is easy to check that the assumptions of the theorem hold. It follows that

\[
\frac{S_n - H_n}{\sigma(S_n)} \Rightarrow N(0,1).
\]
Equivalently, because of the asymptotic behavior of $E(S_n)$ and $V(S_n)$ it is also true that
\[
\frac{S_n - \log n}{\sqrt{\log n}} \implies N(0, 1).
\]

**Note:** $S_n$ describes the distribution of another interesting statistic on random permutations. It is not too difficult to show by induction (using an amusing construction often referred to as the **Chinese restaurant process**) that if $\sigma \in S_n$ is a uniformly random permutation on $n$ elements, then the number of cycles in $\sigma$ is a random variable which is equal in distribution to $S_n$.

13.2.2 Erdös-Kac theorem

**Theorem 13.4** (Erdös-Kac theorem (1940)). Let $g(m)$ denote the number of prime divisors of an integer $k$ (for example, $g(28) = 2$). For each $n \geq 1$, let $X_n$ be a uniformly random integer chosen in $\{1, 2, \ldots, n\}$, and let $Y_n = g(X_n)$ be the number of prime divisors of $X_n$. Then we have
\[
\frac{Y_n - \log \log n}{\sqrt{\log \log n}} \implies N(0, 1).
\]
In other words, for any $x \in \mathbb{R}$ we have
\[
\frac{1}{n} \# \left\{ 1 \leq k \leq n : g(k) \leq \log \log n + k \sqrt{\log \log n} \right\} \xrightarrow{n \to \infty} \Phi(x).
\]

Note that $Y_n$ can be written in the form $\sum_{p \leq n} 1_{\{p \mid X_n\}}$, namely the sum over all primes $p \leq n$ of the indicator of the event that $X_n$ is divisible by $p$. The probability that $X_n$ is divisible by $p$ is roughly $1/p$, at least if $p$ is significantly smaller than $n$. Therefore we can expect $Y_n$ to be on the average around
\[
\sum_{\text{prime } p \leq n} \frac{1}{p},
\]
a sum that is known (thanks to Euler) to behave roughly like $\log \log n$. The Erdös-Kac theorem is intuitively related to the observation that these indicators $1_{\{p \mid X_n\}}$ for different $p$’s are also close to being independent (a fact which follows from the Chinese remainder theorem). Of course, they are only approximately independent, and making these observations
precise is the challenge to proving the theorem. In fact, many famous open problems in
number theory (even the Riemann Hypothesis, widely considered to be the most important
open problem in mathematics) can be formulated in terms of a statement about approxi-
mate independence (in some loose sense) of some arithmetic sequence relating to the prime
numbers.

13.2.3 The Euclidean algorithm

As a final example from number theory, consider the following problem: For some \( n \geq 1 \),
choose \( X_n \) and \( Y_n \) independently and uniformly at random in \( \{1, 2, \ldots, n\} \), and compute their
greatest common divisor (g.c.d.) using the Euclidean algorithm. Let \( N_n \) be the number of
division (with remainder) steps that were required. For example, if \( X = 58 \) and \( Y = 24 \) then
the application of the Euclidean algorithm would result in the sequence of steps

\[
(58, 24) \rightarrow (24, 10) \rightarrow (10, 4) \rightarrow (4, 2) \rightarrow (2, 0),
\]

so 4 division operations were required (and the g.c.d. is 2).

**Theorem 13.5** (CLT for the number of steps in the Euclidean algorithm; D. Hensley (1992)).

There exists a constant \( \sigma_\infty \) (which has a very complicated definition) such that

\[
\frac{N_n - \frac{12 \log 2}{\pi^2} \log n}{\sigma_\infty \sqrt{\log n}} \Rightarrow N(0, 1).
\]

Hensley’s theorem was in recent years significantly generalized and the techniques ex-
tended by Brigitte Vallée, a French mathematician. The fact that the average value of \( N_n \) is
approximately \( (12 \log 2 / \pi^2) \log n \) was previously known from work of Heilbronn and Dixon
in 1969–1970, using ideas dating back to Gauss, who discovered the probability distribution
now called the “Gauss measure”. This is the probability distribution on \((0, 1)\) with den-
sity \( \frac{1}{\log 2(1+x)} \), which Gauss found (but did not prove!) describes the limiting distribution
of the ratio of a pair of independent \( U(0,1) \) random variables after many iterations of the
Chapter 14: Additional topics

14.1 The Kolmogorov 0-1 law

In this section we prove a well-known and easy result due to Kolmogorov, the Kolmogorov 0-1 law. This will be useful in the next section.

**Theorem 14.1** (Kolmogorov 0-1 law). Let $X_1, X_2, \ldots$ be a sequence of independent random variables in some probability space $(\Omega, \mathcal{F}, P)$. An event $A \in \mathcal{F}$ is called a tail event if

$$A \in \sigma(X_n, X_{n+1}, \ldots)$$

for all $n$. That is, one can tell whether $A$ occurred or not by looking at the sequence $X_1, X_2, \ldots$, and the occurrence of $A$ is unaffected by changing a finite number of $X_k$’s. (Note that the set of tail events is a $\sigma$-algebra, called the tail $\sigma$-algebra of the sequence, and denoted $\mathcal{T}$; formally, $\mathcal{T} = \cap_{n \geq 1} \sigma(X_n, X_{n+1}, \ldots)$). Then for any tail event $A$ we have that $P(A) = 0$ or $P(A) = 1$.

**Proof.** It will be enough to prove the somewhat strange statement that the tail event $A$ is independent of itself, since in that case we’ll have

$$P(A) = P(A \cap A) = P(A)P(A) = P(A)^2,$$

which would imply the claim, since the only solutions to the equation $x^2 = x$ are $x = 0$ and $x = 1$. The fact that a tail event is independent of itself is a consequence of the following two claims: 1. If $A \in \sigma(X_1, \ldots, X_n)$ and $B \in \sigma(X_{n+1}, X_{n+2}, \ldots)$ then $A$ and $B$ are independent. This follows by observing that $\cup_{k \geq 1} \sigma(X_{n+1}, X_{n+2}, \ldots, X_{n+k})$ is a $\pi$-system generating $\sigma(X_{n+1}, X_{n+2}, \ldots)$, and for $B$ in the $\pi$-system the claim is trivial. 2. If $A \in \sigma(X_1, X_2, \ldots)$ and $B \in \mathcal{T}$ then $A$ and $B$ are independent. The fact that is true when $A \in \sigma(X_1, \ldots, X_n)$ for some $n$ follows from claim 1. But $\cup_{n \geq 1} \sigma(X_1, \ldots, X_n)$ is a $\pi$-system generating $\sigma(X_1, X_2, \ldots)$, so the same is true also for $A$ in the generated $\sigma$-algebra. □

**Example 14.2.** The events \(\{\lim_{(275,629),(340,645)}n \rightarrow \infty X_n \text{ exist}\}\) and \(\{\sum_{n=1}^{\infty} X_n \text{ converges}\}\) are tail events.
14.2 The Kolmogorov three-series theorem

As a further application of the Lindeberg-Feller central limit theorem, we prove the Kolmogorov three-series theorem (Theorem 9.6).

Proof of Theorem 9.6. Denote \( Y_n = X_n 1_{\{|X_n| \leq 1\}} \). Assume that the eponymous three series

\[
\sum_{n=1}^{\infty} P(|X_n| > 1) = \sum_{n=1}^{\infty} P(X_n \neq Y_n), \tag{17}
\]

\[
\sum_{n=1}^{\infty} E(Y_n), \tag{18}
\]

\[
\sum_{n=1}^{\infty} V(Y_n) \tag{19}
\]

all converge. Applying Theorem 9.5 to the random variables \( Y_n - E(Y_n) \), from the assumption that (19) converges we infer that the series \( \sum_{n=1}^{\infty} (Y_n - E(Y_n)) \) converges almost surely. Since (18) converges, this also means that \( \sum_n Y_n \) converges almost surely. Since (17) converges we get using the first Borel-Cantelli lemma that the event \( \{X_n \neq Y_n \text{ i.o.}\} \) has probability 0. Outside this event, the series \( \sum_n X_n \) converges if and only if \( \sum_n Y_n \) converges, so \( \sum_n X_n \) also converges almost surely.

Next, for the converse claim, assume that \( \sum_n X_n \) converges with positive probability. By the Kolmogorov 0-1 law, it therefore converges a.s. We need to show that the series (17), (18), (19) converge.

First, note that (17) must converge, since if it doesn’t, the second Borel-Cantelli lemma implies that the event \( \{|X_n| > 1 \text{ i.o.}\} \) has probability one, which would imply that \( \sum X_n \) diverges almost surely.

Second, assume by contradiction that (19) diverges, or equivalently that

\[
v_n := \sum_{k=1}^{n} V(Y_n) \to \infty \text{ as } n \to \infty.
\]

We apply Theorem 13.2 to the triangular array

\[
X_{n,k} = v_n^{-1/2} (Y_k - EY_k).
\]

Assumptions 1, 2 and 3 of the theorem are trivially satisfied (with \( \sigma^2 = \sum_{k=1}^{n} V(X_{n,k}) = 1 \) for all \( n \)). For assumption 4, note that \( |X_{n,k}| \leq 2v_n^{-1/2} \), so \( X_{n,k} 1_{\{|X_{n,k}| > \epsilon\}} = 0 \) for all \( k \) if
\(v_n > 4/\epsilon^2\), which holds for \(n\) large enough. Thus, the assumptions of the theorem are valid and hence we obtain the conclusion that \(S_n = \sum_{k=1}^{n} X_{n,k} \implies N(0,1)\) as \(n \to \infty\). Define a sequence (of numbers, not random variables)

\[
t_n = v_n^{-1/2} \sum_{k=1}^{n} EY_k = S_n - v_n^{-1/2} \sum_{k=1}^{n} Y_k,
\]

and note that on the event \(\{\sum_{n} X_n \text{ converges}\}\) (in which case clearly \(\sum_{n} Y_n\) also converges), which we assumed has probability 1, \(S_n - t_n = v_n^{-1/2} \sum_{k=1}^{n} Y_k \to 0\) as \(n \to \infty\). This is easily seen to be in contradiction to the convergence in distribution of \(S_n\) to a limiting distribution of a non-constant random variable. So we have shown that (19) converges.

Finally, having shown that (19) converges, we conclude from Theorem 9.5 that the series \(\sum_{n} (Y_n - E(Y_n))\) converges almost surely. We already saw that on the event where \(\{\sum_{n} X_n \text{ converges}\}\), which we assumed has positive probability, also \(\sum_{n} Y_n\) converges, and therefore the series \(\sum_{n} E(Y_n) = \sum (Y_n - (Y_n - E(Y_n)))\) also converges.

14.3 The Poisson limit law

The Poisson distribution is the one-parameter family of distributions \(\text{Poisson}(\lambda), \lambda > 0\), where \(X \sim \text{Poisson}(\lambda)\) is a discrete random variable satisfying

\[
P(X = k) = e^{-\lambda} \frac{\lambda^k}{k!}, \quad k = 0, 1, 2, \ldots
\]

This distribution arises naturally as measuring the number of successful coin tossing experiments when one performs a large number of independent coin tosses with equal bias, as long as the expected number of successes remains bounded away from 0 and \(\infty\). That is, if \(X_1, X_2, \ldots, X_n\) denote i.i.d. Bernoulli random variables with bias \(p = p(n)\) (which is a function of \(n\)), and \(S_n = \sum_{k=1}^{n}\), then if \(n \cdot p(n) \to \lambda\) as \(n \to \infty\), it is a simple exercise to check that

\[
S_n \implies \text{Poisson}(\lambda).
\]

As in the case of the Central Limit Theorem, it turns out that the i.i.d. condition can be significantly weakened, so in fact the Poisson distribution arises almost universally as the limit law for counting numbers of “rare events,” i.e., sums of indicator functions of many
independent or weakly correlated events each of which has a small chance of success, in the asymptotic regime in which the expected number of successes converges to a constant. For this reason, the Poisson distribution is considered an excellent model for many real-life phenomena, e.g.:

- The number of typographical errors in a web page or book chapter.
- The number of radioactive particles emitted from a chunk of radioactive material in a unit of time.
- The number of cars passing a point on a remote desert road in an hour.
- The number of incandescent light-bulbs burning out in your house each month.
- Etc. (try to think of more examples from science or your daily life...)

Our goal is to prove the following generalization of (20), analogous to the Lindeberg-Feller extension of the Central Limit Theorem. The technique used in the proof is also similar and uses characteristic functions.

**Theorem 14.3.** Let \((X_{n,m})_{1 \leq m \leq n}\) be a triangular array of random variables such that for each \(n \geq 1\), the random variables \(X_{n,1}, \ldots, X_{n,n}\) are independent, and each \(X_{n,m}\) satisfies

\[
P(X_{n,m} = 1) = p_{n,m}, \quad P(X_{n,m} = 0) = 1 - p_{n,m}.
\]

Denote \(S_n = \sum_{m=1}^{n} X_m\). Assume that the biases \((p_{n,m})_{n,m}\) satisfy the following conditions:

(i) \(E S_n = \sum_{m=1}^{n} p_{n,m} \to \lambda \in (0, \infty)\) as \(n \to \infty\).

(ii) \(\max_{1 \leq m \leq n} p_{n,m} \to 0\) as \(n \to \infty\).

Then \(S_n \implies \text{Poisson}(\lambda)\).

**Proof.** Let \(\varphi_{n,m}(t) = \varphi_{X_{n,m}}(t) = E(\exp(itX_{n,m})) = (1 - p_{n,m}) + p_{n,m}e^{it}\) denote the characteristic function of \(X_{n,m}\). The ch. f. of \(S_n\) is then

\[
\varphi_{S_n} = \prod_{k=1}^{n} \varphi_{n,m}(t) = \prod_{k=1}^{n} ((1 - p_{n,m}) + p_{n,m}e^{it}).
\]
Our goal is to show that $\varphi_{S_n}(t) \to \varphi_{Z}(t)$ where $Z \sim \text{Poisson}(\lambda)$. From a past homework computation we know that

$$\varphi_{Z}(t) = \sum_{k=0}^{\infty} e^{-\lambda} \frac{\lambda^k}{k!} e^{ikt} = \exp(\lambda(e^{it} - 1)) = \lim_{n \to \infty} \prod_{m=1}^{n} \exp(p_{n,m}(e^{it} - 1))$$

(by assumption (i)),

so let us investigate how closely $\prod_{m=1}^{n} \varphi_{n,m}(t)$ is approximated by $\prod_{m=1}^{n} \exp(p_{n,m}(e^{it} - 1))$.

Note that for any $0 \leq p \leq 1$, we have

$$|\exp(p(e^{it} - 1))| = \exp(p \Re(e^{it} - 1)) \leq \exp(0) = 1,$$

$$|1 - p + pe^{it}| = |1 + p(e^{it} - 1)| \leq 1 \text{ (a convex combination of 1 and } e^{it}).$$

We therefore get using the exercise below that

$$\left| \prod_{m=1}^{n} \exp\left(p_{n,m}(e^{it} - 1)\right) - \prod_{m=1}^{n} \left(1 + p_{n,m}(e^{it} - 1)\right) \right|$$

$$\leq \sum_{m=1}^{n} \left| \exp\left(p_{n,m}(e^{it} - 1)\right) - \left(1 + p_{n,m}(e^{it} - 1)\right) \right|$$

$$\leq 10 \sum_{m=1}^{n} p_{n,m}^2 |e^{it} - 1|^2$$

$$\leq 40 \left( \max_{1 \leq m \leq n} p_{n,m} \right) \sum_{m=1}^{n} p_{n,m} \to 0 \text{ as } n \to \infty.$$

This is exactly what was needed to finish the proof.

Exercise 14.4. (i) Let $z_1, \ldots, z_n, w_1, \ldots, w_n$ be complex numbers such that $|z_m|, |w_m| \leq 1$ for all $1 \leq m \leq n$. Prove that

$$\left| \prod_{m=1}^{n} z_m - \prod_{m=1}^{n} w_m \right| \leq \sum_{m=1}^{n} |z_m - w_m|.$$

(ii) Prove that if $z$ is a complex number with $|z| \leq 2$ then

$$|\exp(z) - (1 + z)| \leq 10|z|^2.$$
Exercises

1. (a) If $(\Omega, \mathcal{F}, P)$ is a probability space and $A, B \in \mathcal{F}$ are events such that $P(B) \neq 0$, the conditional probability of $A$ given $B$ is denoted $P(A|B)$ and defined by

$$P(A|B) = \frac{P(A \cap B)}{P(B)}.$$

Prove the total probability formula: if $A, B_1, B_2, \ldots, B_k \in \mathcal{F}$ such that $\Omega$ is the disjoint union of $B_1, \ldots, B_k$ and $P(B_i) \neq 0$ for $1 \leq i \leq k$, then

$$P(A) = \sum_{i=1}^{k} P(B_i)P(A|B_i). \quad \text{(TPF)}$$

(b) An urn initially contains one white ball and one black ball. At each step of the experiment, a ball is drawn at random from the urn, then put back and another ball of the same color is added. Prove that the number of white balls that are in the urn after $N$ steps is a uniform random number in $\{1, 2, \ldots, N+1\}$. That is, the event that the number of white balls after step $N$ is equal to $k$ has probability $1/(N + 1)$ for each $1 \leq k \leq N + 1$. (Note: The idea is to use (TPF), but there is no need to be too formal about constructing the relevant probability space — you can assume an intuitive notion of probabilities.)

2. If $\Omega = \{1, 2, 3\}$, list all the possible $\sigma$-algebras of subsets of $\Omega$.

3. Let $(\Omega, \mathcal{F})$ be a measurable space. A pre-probability measure is a function $P : \mathcal{F} \to [0, 1]$ that satisfies

$$P(\emptyset) = 0, \quad P(\Omega) = 1. \quad \text{(P1)}$$

If a pre-probability measure $P$ satisfies

$$A_1, A_2, \ldots \in \mathcal{F} \text{ are pairwise disjoint} \implies P(\cup_{n=1}^{\infty} A_n) = \sum_{n=1}^{\infty} P(A_n). \quad \text{(P2)}$$

then we say that it is $\sigma$-additive. If it satisfies

$$A_1, \ldots, A_n \in \mathcal{F} \text{ are pairwise disjoint} \implies P(\cup_{k=1}^{n} A_k) = \sum_{k=1}^{n} P(A_k). \quad \text{(P3)}$$
then we say that it is additive. Recall that we defined a probability measure to be a pre-probability measure that is $\sigma$-additive.

We say that a pre-probability measure satisfies the continuity properties if it satisfies

$$
(A_n)_{n=1}^{\infty} \subseteq \mathcal{F}, \ A_n \subset A_{n+1} \ \forall n \implies P(\bigcup_{n=1}^{\infty} A_n) = \lim_{n \to \infty} P(A_n), \quad \text{(CONT1)}
$$

$$
(A_n)_{n=1}^{\infty} \subseteq \mathcal{F}, \ A_n \supset A_{n+1} \ \forall n \implies P(\bigcap_{n=1}^{\infty} A_n) = \lim_{n \to \infty} P(A_n). \quad \text{(CONT2)}
$$

Prove that a probability measure satisfies the continuity properties, and that an additive pre-probability measure that satisfies the first continuity property (CONT1) ("continuity from below") is $\sigma$-additive, and is therefore a probability measure.

4. (a) A coin has some bias $p \in (0, 1)$, so when tossed it comes up Heads with probability $p$, or Tails with probability $1 - p$. Suppose the coin is tossed $N$ times independently, and let $A_{N,k}$ denote the event that the result came up Heads exactly $k$ times. Refresh your memory concerning why the Binomial Distribution Formula, which says that

$$
P(A_{N,k}) = \binom{N}{k} p^k (1 - p)^{N-k}, \quad \text{(BINOM)}
$$

is true. You may submit a short written explanation to test your understanding, but it is not required.

(b) A group of $N$ prisoners is locked up in a prison, each in a separate cell with no ability to communicate with the other prisoners. Each cell contains a mysterious on/off electrical switch. One evening the warden visits each of the prisoners and presents them with the following dilemma: During the night each prisoner must choose whether to leave his switch in the on or off position. If at midnight exactly one of the switches is in the on position, all the prisoners will be set free in the morning; otherwise they will all be executed!

The prisoners cannot coordinate their actions, but they are all rational, know calculus and probability theory, and each is equipped with a random number generator. Find the strategy that the prisoners will take to maximize their chance of survival, and compute what that chance is, as a function of $N$ and in the limit when $N$ is very large. For extra fun, try to guess in advance how big or small you expect the survival likelihood to be, and see how your guess measures up to the actual result.
5. (a) Let \( \Omega \) be a set, and let \( S = \{ F_i \}_{i \in I} \) be some collection of \( \sigma \)-algebras of subsets of \( \Omega \), indexed by some index set \( I \) (note that \( S \) is a set of subsets of \( \Omega \) - try to avoid dizziness!). Prove that the intersection of all the \( F_i \)'s (i.e., the collection of subsets of \( \Omega \) that are elements of all the \( F_i \)'s) is also a \( \sigma \)-algebra.

(b) Let \( \Omega \) be a set, and let \( A \) be a collection of subsets of \( \Omega \). Prove that there exists a unique \( \sigma \)-algebra \( \sigma(\mathcal{A}) \) of subsets of \( \Omega \) that satisfies the following two properties:

(i) \( A \subset \sigma(\mathcal{A}) \) (in words, \( \sigma(\mathcal{A}) \) contains all the elements of \( A \)).

(ii) \( \sigma(\mathcal{A}) \) is the minimal \( \sigma \)-algebra satisfying property 1 above, in the sense that if \( F \) is any other \( \sigma \)-algebra that contains all the elements of \( A \), then \( \sigma(\mathcal{A}) \subset F \).

The \( \sigma \)-algebra \( \sigma(\mathcal{A}) \) is called the \( \sigma \)-algebra generated by \( \mathcal{A} \).

**Hint for (b).** Let \((\mathcal{F}_i)_{i \in I}\) be the collection of all \( \sigma \)-algebras of subsets of \( \Omega \) that contain \( \mathcal{A} \). This is a non-empty collection, since it contains for example \( \mathcal{P}(\Omega) \), the set of all subsets of \( \Omega \). Any \( \sigma \)-algebra \( \sigma(\mathcal{A}) \) that satisfies the two properties above is necessarily a subset of any of the \( \mathcal{F}_i \)'s, hence it is also contained in the intersection of all the \( \mathcal{F}_i \)'s, which is a \( \sigma \)-algebra by part (a) of the question.

6. (a) Let \( X \) be a random variable with distribution function \( F_X \) and piecewise continuous density function \( f_X \). Let \([a, b] \subset \mathbb{R}\) be an interval (possibly infinite) such that \( \mathbb{P}(X \in [a, b]) = 1 \),

and let \( g : [a, b] \to \mathbb{R} \) be a monotone (strictly) increasing and differentiable function. Prove that the random variable \( Y = g(X) \) (this is the function on \( \Omega \) defined by \( Y(\omega) = g(X(\omega)) \), in other words the composition of the two functions \( g \) and \( X \)) has density function

\[
 f_Y(x) = \begin{cases} 
 \frac{f_X(g^{-1}(x))}{g'(g^{-1}(x))} & x \in (g(a), g(b)), \\
 0 & \text{otherwise}. 
\end{cases}
\]

(b) If \( \lambda > 0 \), we say that a random variable has the exponential distribution with parameter \( \lambda \) if

\[
 F_X(x) = \begin{cases} 
 0 & x < 0, \\
 1 - e^{-\lambda x} & x \geq 0, 
\end{cases}
\]
and denote this $X \sim \text{Exp}(\lambda)$. Find an algorithm to produce a random variable with \text{Exp}(\lambda) distribution using a random number generator that produces uniform random numbers in $(0, 1)$. In other words, if $U \sim U(0, 1)$, find a function $g : (0, 1) \to \mathbb{R}$ such that the random variable $X = g(U)$ has distribution \text{Exp}(\lambda).

(c) We say that a non-negative random variable $X \geq 0$ has the **lack of memory property** if it satisfies that

$$P(X \geq t \mid X \geq s) = P(X \geq t - s) \quad \text{for all } 0 < s < t.$$ 

Prove that exponential random variables have the lack of memory property.

(d) Prove that any non-negative random variable that has the lack of memory property has the exponential distribution with some parameter $\lambda > 0$. (This is easier if one assumes that the function $G(x) = P(X \geq x)$ is differentiable on $[0, \infty)$, so you can make this assumption if you fail to find a more general argument).

7. (a) Prove the **inclusion-exclusion principle**: If $A_1, \ldots, A_n$ are events in a probability space $(\Omega, \mathcal{F}, P)$, then

$$P\left(\bigcup_{k=1}^{n} A_k\right) = s_1 - s_2 + s_3 - s_4 + s_5 - \ldots + (-1)^{n-1}s_n,$$

where

$$s_1 = P(A_1) + P(A_2) + \ldots + P(A_n) = \sum_{k=1}^{n} P(A_k),$$

$$s_2 = \sum_{1 \leq k_1 < k_2 \leq n} P(A_{k_1} \cap A_{k_2}),$$

$$s_3 = \sum_{1 \leq k_1 < k_2 < k_3 \leq n} P(A_{k_1} \cap A_{k_2} \cap A_{k_3}),$$

$$\vdots$$

$$s_d = \sum_{1 \leq k_1 < \ldots < k_d \leq n} P(A_{k_1} \cap A_{k_2} \cap \ldots \cap A_{k_d}),$$

$$\vdots$$

$$s_n = P(A_1 \cap A_2 \cap \ldots \cap A_n).$$
(b) $N$ letters addressed to different people are inserted at random into $N$ envelopes that are labelled with the names and addresses of the $N$ recipients, such that all $N!$ possible matchings between the letters and envelopes are equally likely. What is the probability of the event that no letter will arrive at its intended destination? Compute this probability for any $N$, and in the limit when $N \to \infty$.

8. Let $F$ be the distribution function

$$F(x) = \begin{cases} 
0 & x < 0, \\
\frac{1}{3} + \frac{1}{6}x & 0 \leq x < 1, \\
\frac{1}{2} & 1 \leq x < 2, \\
1 - \frac{1}{4}e^{2-x} & x \geq 2.
\end{cases}$$

Compute the lower and upper quantile functions of $F$, defined by

$$X_* (p) = \sup \{ x : F(x) < p \},$$

$$X^* (p) = \inf \{ x : F(x) > p \},$$

$(0 < p < 1)$.

A recommended way is to plot $F$ on paper and then figure out the quantiles by “eyeballing”. Of course, the answer should be spelled out in precise formulas.

9. A drunken archer shoots at a target hanging on a wall 1 unit of distance away. Since he is drunk, his arrow ends up going in a random direction at an angle chosen uniformly in $(-\pi/2, \pi/2)$ (an angle of 0 means he will hit the target precisely) until it hits the wall. Ignoring gravity and the third dimension, compute the distribution function (and density function if it exists) of the random distance from the hitting point of the arrow to the target.

10. (a) Let $(\Omega_1, \mathcal{F}_1, \mathbb{P}_1)$ be a probability space, let $(\Omega_2, \mathcal{F}_2)$ be a measurable space, and let $f : \Omega_1 \to \Omega_2$ be a measurable function. Verify that the function $\mathbb{P}_2 : \mathcal{F}_2 \to [0, 1]$ defined by

$$\mathbb{P}_2(A) = \mathbb{P}_1(f^{-1}(A))$$

is a probability measure. This probability measure is called the push-forward measure of $\mathbb{P}_1$ under $f$. 93
(b) For a real number $x$, denote the integer part of $x$ by

$$|x| = \sup\{n \in \mathbb{Z} : n \leq x\},$$

and denote the fractional part of $x$ by

$$\{x\} = x - |x|.$$

Let $((0, 1), \mathcal{B}, \mathbf{P})$ be the unit interval with the $\sigma$-algebra of Borel subsets and the Lebesgue probability measure, corresponding to the experiment of choosing a uniform random number in $(0, 1)$. Define a sequence of functions $R_1, R_2, \ldots : (0, 1) \to \mathbb{R}$ by

$$R_n(x) = \begin{cases} 0 & 0 \leq \{2^{n-1}x\} < 1/2, \\ 1 & 1/2 \leq \{2^{n-1}x\} < 1. \end{cases}$$

For any $n \in \mathbb{N}$ and $a_1, a_2, \ldots, a_n \in \{0, 1\}$, denote by $B_n(a_1, \ldots, a_n)$ the set

$$B_n(a_1, \ldots, a_n) = \{x \in (0, 1) : R_1(x) = a_1, R_2(x) = a_2, \ldots, R_n(x) = a_n\}.$$

Find a good explicit description for this set (“the set of all $x$’s such that ...”), and deduce from it that

$$\mathbf{P}(B_n(a_1, \ldots, a_n)) = \frac{1}{2^n}.$$

(c) Define a function $f : (0, 1) \to \{0, 1\}^\mathbb{N}$ by

$$f(x) = (R_1(x), R_2(x), R_3(x), \ldots).$$

Prove that $f$ is a measurable function when the space $\{0, 1\}^\mathbb{N}$ is equipped with the $\sigma$-algebra generated by the sets

$$A_n(1) = \{(x_1, x_2, \ldots) \in \{0, 1\}^\mathbb{N} : x_n = 1\}.$$

(d) Prove that the push-forward of Lebesgue measure under $f$ is the probability measure corresponding to the random experiment of an infinite sequence of fair coin tosses.
11. Let $X$ be an exponential r.v. with parameter $\lambda$, i.e., $F_X(x) = (1-e^{-\lambda x})1_{[0,\infty)}(x)$. Define random variables

\begin{align*}
Y &= \lfloor X \rfloor := \sup\{n \in \mathbb{Z} : n \leq x\} \quad \text{("the integer part of $X""),} \\
Z &= \{X\} := X - \lfloor X \rfloor \quad \text{("the fractional part of $X"").}
\end{align*}

(a) Compute the (1-dimensional) distributions of $Y$ and $Z$ (in the case of $Y$, since it’s a discrete random variable it is most convenient to describe the distribution by giving the individual probabilities $P(Y = n), n = 0, 1, 2, \ldots$; for $Z$ one should compute either the distribution function or density function).

(b) Show that $Y$ and $Z$ are independent. (Hint: check that $P(Y = n, Z \leq t) = P(Y = n)P(Z \leq t)$ for all $n$ and $t$.)

12. (a) Let $X, Y$ be independent r.v.’s. Define $U = \min(X, Y)$, $V = \max(X, Y)$. Find expressions for the distribution functions $F_U$ and $F_V$ in terms of the distribution functions of $X$ and $Y$.

(b) Assume that $X \sim \text{Exp}(\lambda), Y \sim \text{Exp}(\mu)$ (and are independent as before). Prove that $\min(X, Y)$ has distribution $\text{Exp}(\lambda + \mu)$. Try to give an intuitive explanation in terms of the kind of real-life phenomena that the exponential distribution is intended to model (e.g., measuring the time for a light-bulb to burn out, or for a radioactive particle to be emitted from a chunk of radioactive material).

(c) Let $X_1, X_2, \ldots$ be a sequence of independent r.v.’s, all of them having distribution $\text{Exp}(1)$. For each $n \geq 1$ denote

\begin{align*}
M_n &= \max(X_1, X_2, \ldots, X_n) - \log n.
\end{align*}

Compute for each $n$ the distribution function of $M_n$, and find the limit (if it exists)

\begin{align*}
F(x) &= \lim_{n \to \infty} F_{M_n}(x).
\end{align*}

13. If $X, Y$ are r.v.’s with a joint density $f_{X,Y}$, the identity

\begin{align*}
P((X, Y) \in A) &= \iint_A f_{X,Y}(x, y) \, dx \, dy
\end{align*}
holds for all “reasonable” sets $A \subset \mathbb{R}^2$ (in fact, for all Borel-measurable sets, but that requires knowing what that integral means for a set such as $\mathbb{R}^2 \setminus \mathbb{Q}^2$...). In particular, if $X, Y$ are independent and have respective densities $f_X$ and $f_Y$, so $f_{X,Y}(x, y) = f_X(x) f_Y(y)$, then

$$F_{X+Y}(t) = P(X + Y \leq t) = \int_{-\infty}^{t} \int_{-\infty}^{t-x} f_X(x) f_Y(y) \, dy \, dx.$$ 

Differentiating with respect to $t$ gives (assuming without justification that it is allowed to differentiate under the integral):

$$f_{X+Y}(t) = \int_{-\infty}^{\infty} f_X(x) f_Y(t-x) \, dx.$$ 

Use this formula to compute the distribution of $X+Y$ when $X$ and $Y$ are independent r.v.’s with the following (pairs of) distributions:

(a) $X \sim U[0,1], \ Y \sim U[0,2]$.
(b) $X \sim \text{Exp}(1), \ Y \sim \text{Exp}(1)$.
(c) $X \sim \text{Exp}(1), \ -Y \sim \text{Exp}(1)$.

14. Let $(A_n)_{n=1}^{\infty}$ be a sequence of events in a probability space. Show that

$$1_{\limsup_n A_n} = \limsup_n 1_{A_n}.$$ 

(The lim-sup on the left refers to the lim-sup operation on events; on the right it refers to the lim-sup of a sequence of functions; the identity is an identity of real-valued functions on $\Omega$, i.e., should be satisfied for each individual point $\omega \in \Omega$ in the sample space). Similarly, show (either separately or by relying on the first claim) that

$$1_{\liminf_n A_n} = \liminf_n 1_{A_n}.$$ 

(b) Let $U$ be a uniform random variable in $(0,1)$. For each $n \geq 1$ define an event $A_n$ by

$$A_n = \{U < 1/n\}.$$ 

Note that $\sum_{n=1}^{\infty} P(A_n) = \infty$. However, compute $P(A_n \ i.o.)$ and show that the conclusion of the second Borel-Cantelli lemma does not hold (of course, one of the assumptions of the lemma also doesn’t hold, so there’s no contradiction).
15. If $P,Q$ are two probability measures on a measurable space $(\Omega,\mathcal{F})$, we say that $P$ is \textbf{absolutely continuous with respect to} $Q$, and denote this $P << Q$, if for any $A \in \mathcal{F}$, if $Q(A) = 0$ then $P(A) = 0$.

Prove that $P << Q$ if and only if for any $\epsilon > 0$ there exists a $\delta > 0$ such that if $A \in \mathcal{F}$ and $Q(A) < \delta$ then $P(A) < \epsilon$.

\textbf{Hint.} Apply a certain famous lemma.

\textbf{Note.} The intuitive meaning of the relation $P << Q$ is as follows: suppose there is a probabilistic experiment, and we are told that one of the measures $P$ or $Q$ governs the statistical behavior of the outcome, but we don’t know which one. (This is a situation that arises frequently in real-life applications of probability and statistics.) All we can do is perform the experiment, observe the result, and make a guess. If $P << Q$, any event which is observable with positive probability according to $P$ also has positive $Q$-probability, so we can never rule out $Q$ as the correct measure, although we may get an event with $Q(A) > 0$ and $P(A) = 0$ that enables us to rule out $P$. If we also have the symmetric relation $Q << P$, then we can’t rule out either of the measures.

16. A function $\varphi : (a,b) \to \mathbb{R}$ is called \textbf{convex} if for any $x,y \in (a,b)$ and $\alpha \in [0,1]$ we have

\[ \varphi(\alpha x + (1-\alpha)y) \leq \alpha \varphi(x) + (1-\alpha)\varphi(y). \]

(a) Prove that an equivalent condition for $\varphi$ to be convex is that for any $x < z < y$ in $(a,b)$ we have

\[ \frac{\varphi(z) - \varphi(x)}{z-x} \leq \frac{\varphi(y) - \varphi(z)}{y-z}. \]

Deduce using the mean value theorem that if $\varphi$ is twice continuously differentiable and satisfies $\varphi'' \geq 0$ then it is convex.

(b) Prove \textbf{Jensen’s inequality}, which says that if $X$ is a random variable such that $\mathbb{P}(X \in (a,b)) = 1$ and $\varphi : (a,b) \to \mathbb{R}$ is convex, then

\[ \varphi(\mathbb{E}X) \leq \mathbb{E}(\varphi(X)). \]

\textbf{Hint.} Start by proving the following property of a convex function: If $\varphi$ is convex then at any point $x_0 \in (a,b)$, $\varphi$ has a \textbf{supporting line}, that is, a linear function
$y(x) = ax + b$ such that $y(x_0) = \varphi(x_0)$ and such that $\varphi(x) \geq y(x)$ for all $x \in (a, b)$ (to prove its existence, use the characterization of convexity from part (a) to show that the left-sided derivative of $\varphi$ at $x_0$ is less than or equal to the right-sided derivative at $x_0$; the supporting line is a line passing through the point $(x_0, \varphi(x_0))$ whose slope lies between these two numbers). Now take the supporting line function at $x_0 = EX$ and see what happens.

17. If $X$ is a random variable satisfying $a \leq X \leq b$, prove that
\[ V(X) \leq \frac{(b - a)^2}{4}, \]
and identify when equality holds.

18. Let $X_1, X_2, \ldots$ be a sequence of i.i.d. (independent and identically distributed) random variables with distribution $U(0, 1)$. Define events $A_1, A_2, \ldots$ by
\[ A_n = \{X_n = \max(X_1, X_2, \ldots, X_n)\} \]
(if $A_n$ occurred, we say that $n$ is a record time).

(a) Prove that $A_1, A_2, \ldots$ are independent events.

**Hint.** for each $n \geq 1$, let $\pi_n$ be the random permutation of $(1, 2, \ldots, n)$ obtained by forgetting the values of $(X_1, \ldots, X_n)$ and only retaining their respective order. In other words, define
\[ \pi_n(k) = \#\{1 \leq j \leq n : X_j \leq X_k\}. \]
By considering the joint density $f_{X_1, \ldots, X_n}$ (a uniform density on the $n$-dimensional unit cube), show that $\pi_n$ is a uniformly random permutation of $n$ elements, i.e. $P(\pi_n = \sigma) = 1/n!$ for any permutation $\sigma \in S_n$. Deduce that the event $A_n = \{\pi_n(n) = n\}$ is independent of $\pi_{n-1}$ and therefore is independent of the previous events $(A_1, \ldots, A_{n-1})$, which are all determined by $\pi_{n-1}$.

(b) Define
\[ R_n = \sum_{k=1}^{n} 1_{A_k} = \#\{1 \leq k \leq n : k \text{ is a record time}\}, \quad (n = 1, 2, \ldots). \]
Compute $E(R_n)$ and $V(R_n)$. Deduce that if $(m_n)_{n=1}^\infty$ is a sequence of positive numbers such that $m_n \uparrow \infty$, however slowly, then the number $R_n$ of record times up to time $n$ satisfies

$$\mathbb{P} \left( |R_n - \log n| > m_n \sqrt{\log n} \right) \xrightarrow{n \to \infty} 0.$$ 

19. Compute $E(X)$ and $V(X)$ when $X$ is a random variable having each of the following distributions:

(a) $X \sim \text{Binomial}(n,p)$.

(b) $X \sim \text{Poisson}(\lambda)$, i.e., $\mathbb{P}(X = k) = e^{-\lambda} \frac{\lambda^k}{k!}$, $(k = 0, 1, 2, \ldots)$.

(c) $X \sim \text{Geom}(p)$, i.e., $\mathbb{P}(X = k) = p(1-p)^{k-1}$, $(k = 1, 2, \ldots)$.

(d) $X \sim U\{1, 2, \ldots, n\}$ (the discrete uniform distribution on $\{1, 2, \ldots, n\}$).

(e) $X \sim U(a,b)$ (the uniform distribution on the interval $(a,b)$).

(f) $X \sim \text{Exp}(\lambda)$

20. (a) If $X, Y$ are independent r.v.’s taking values in $\mathbb{Z}$, show that

$$\mathbb{P}(X + Y = n) = \sum_{k=-\infty}^{\infty} \mathbb{P}(X = k) \mathbb{P}(Y = n-k) \quad (n \in \mathbb{Z})$$

(compare this formula with the convolution formula in the case of r.v.’s with density).

(b) Use this to show that if $X \sim \text{Poisson}(\lambda)$ and $Y \sim \text{Poisson}(\mu)$ are independent then $X + Y \sim \text{Poisson}(\lambda + \mu)$. (Recall that for a parameter $\lambda > 0$, we say that $X \sim \text{Poisson}(\lambda)$ if $\mathbb{P}(X = k) = e^{-\lambda} \frac{\lambda^k}{k!}$ for $k = 0, 1, 2, \ldots$).

(c) Use the same “discrete convolution” formula to prove directly that if $X \sim \text{Bin}(n,p)$ and $Y \sim \text{Bin}(m,p)$ are independent then $X + Y \sim \text{Bin}(n+m,p)$. You may make use of the combinatorial identity (known as the Vandermonde identity or Chu-Vandermonde identity)

$$\sum_{j=0}^{k} \binom{n}{j} \binom{m}{k-j} = \binom{n+m}{k}, \quad (n,m \geq 0, \ 0 \leq k \leq n+m).$$

As a bonus, try to find a direct combinatorial proof for this identity. An amusing version of the answer can be found at:
21. Prove that if $X$ is a random variable that is independent of itself, then $X$ is a.s. constant, i.e., there is a constant $c \in \mathbb{R}$ such that $P(X = c) = 1$.

22. (a) If $X \geq 0$ is a nonnegative r.v. with distribution function $F$, show that

$$E(X) = \int_0^\infty P(X \geq x) \, dx.$$ 

(b) Prove that if $X_1, X_2, \ldots$, is a sequence of independent and identically distributed ("i.i.d.") r.v.'s, then

$$P(|X_n| \geq n \text{ i.o.}) = \begin{cases} 0 & \text{if } E|X_1| < \infty, \\ 1 & \text{if } E|X_1| = \infty. \end{cases}$$

(c) Deduce the following converse to the Strong Law of Large Numbers in the case of undefined expectations: If $X_1, X_2, \ldots$ are i.i.d. and $EX_1$ is undefined (meaning that $EX_1^+ = EX_1^- = \infty$) then

$$P \left( \lim_{n \to \infty} \frac{1}{n} \sum_{k=1}^n X_k \text{ does not exist} \right) = 1.$$ 

23. Let $X$ be a r.v. with finite variance, and define a function $M(t) = E|X - t|$, the "mean absolute deviation of $X$ from $t". The goal of this question is to show that the function $M(t)$, like its easier to understand and better-behaved cousin, $E(X - t)^2$ (the "moment of inertia" around $t$, which by the Huygens-Steiner theorem is simply a parabola in $t$, taking its minimum value of $V(X)$ at $t = EX$), also has some unexpectedly nice properties.

(a) Prove that $M(t) \geq |t - EX|$.

(b) Prove that $M(t)$ is a convex function.

(c) Prove that

$$\int_{-\infty}^\infty \left(M(t) - |t - EX|\right) dt = V(X).$$

100
(see hints below). Deduce in particular that $M(t) - |t - \mathbf{E}X| \xrightarrow{\ t \to \pm \infty \ t} 0$ (again under the assumption that $\mathbf{V}(X) < \infty$). If it helps, you may assume that $X$ has a density $f_X$.

(d) Prove that if $t_0$ is a (not necessarily unique) minimum point of $M(t)$, then $t_0$ is a median (that is, a 0.5-quantile) of $X$.

(e) Optionally, draw (or, at least, imagine) a diagram showing the graphs of the two functions $M(t)$ and $|t - \mathbf{E}X|$ illustrating schematically the facts (a)–(d) above.

**Hints.** For (c), assume first (without loss of generality - why?) that $\mathbf{E}X = 0$. Divide the integral into two integrals, on the positive real axis and the negative real axis. For each of the two integrals, by decomposing $|X - t|$ into a sum of its positive and negative parts and using the fact that $\mathbf{E}X = 0$ in a clever way, show that one may replace the integrand $(\mathbf{E}|X - t| - |t|)$ by a constant multiple of either $\mathbf{E}(X - t)_+$ or $\mathbf{E}(X - t)_-$, and proceed from there.

For (d), first, develop your intuition by plotting the function $M(t)$ in a couple of cases, for example when $X \sim \text{Binom}(1, 1/2)$ and when $X \sim \text{Binom}(2, 1/2)$. Second, if $t_0 < t_1$, plot the graph of the function $x \to \frac{|x - t_1| - |x - t_0|}{t_1 - t_0}$, and deduce from this a formula for $M'(t_0^+)$ and (by considering $t_1 < t_0$ instead) a similar formula for $M'(t_0^-)$, the right- and left-sided derivatives of $M$ at $t_0$, respectively. On the other hand, think how the condition that $t_0$ is a minimum point of $M(t)$ can be expressed in terms of these one-sided derivatives.

24. (a) Let $\Gamma(t)$ denote the Euler gamma function, defined by

$$\Gamma(t) = \int_0^\infty e^{-x}x^{t-1} \, dx, \quad (t > 0).$$

Show that the special value $\Gamma(1/2) = \sqrt{\pi}$ of the gamma function is equivalent to the integral evaluation $\sqrt{2\pi} = \int_{-\infty}^{\infty} e^{-x^2/2} \, dx$ (which is equivalent to the standard normal density being a density function).

(b) Prove that the Euler gamma function satisfies for all $t > 0$ the identity

$$\Gamma(t + 1) = t \Gamma(t).$$
(This identity immediately implies the fact that \( \Gamma(n + 1) = n! \) for integer \( n \geq 0 \).

(c) Find a formula for the values of \( \Gamma(\cdot) \) at half-integers, that is,

\[
\Gamma\left(n + \frac{1}{2}\right) = ?, \quad (n \geq 0).
\]

25. Compute \( \mathbf{E}X^n \) when \( n \geq 0 \) is an integer and \( X \) has each of the following distributions:

(a) \( X \sim U(a, b) \)

(b) \( X \sim \text{Exp}(\lambda) \)

(c) \( X \sim \text{Gamma}(\alpha, \lambda) \), i.e. \( f_X(x) = \frac{\lambda^\alpha}{\Gamma(\alpha)} e^{-\lambda x} x^{\alpha-1}, \quad (x > 0) \).

(d) \( X \sim \text{Beta}(a, b) \), i.e. \( f_X(x) = \frac{1}{B(a,b)} x^{a-1}(1-x)^{b-1}, \quad (0 < x < 1) \), where

\[
B(a,b) = \int_0^1 u^{a-1}(1-u)^{b-1} \, du = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)}
\]

is the Euler beta function.

(e) \( X \sim N(0,1) \). In this case, identify \( \mathbf{E}X^n \) combinatorially as the number of matchings of a set of size \( n \) into pairs (for example, if a university dorm has only 2-person housing units, then when \( n \) is even this is the number of ways to divide \( n \) students into pairs of roommates; no importance is given to the ordering of the pairs).

(f) \( X \sim N(1,1) \). In this case, identify \( \mathbf{E}X^n \) combinatorially as the number of involutions (permutations which are self-inverse) of a set of \( n \) elements. To count the involutions, it is a good idea to divide them into classes according to how many fixed points they have. (Note: the expression for \( \mathbf{E}(X^n) \) may not have a very simple form.)

26. Let \( f : [0, 1] \rightarrow \mathbb{R} \) be a continuous function. Prove that

\[
\int_0^1 \int_0^1 \ldots \int_0^1 f\left(\frac{x_1 + x_2 + \ldots + x_n}{n}\right) \, dx_1 \, dx_2 \ldots \, dx_n \xrightarrow{n \rightarrow \infty} f(1/2).
\]

**Hint.** Interpret the left-hand side as an expected value; use the laws of large numbers.

27. A bowl contains \( n \) spaghetti noodles arranged in a chaotic fashion. Bob performs the following experiment: he picks two random ends of noodles from the bowl (chosen
uniformly from the $2n$ possible ends), ties them together, and places them back in the bowl. Then he picks at random two more ends (from the remaining $2n - 2$), ties them together and puts them back, and so on until no more loose ends are left.

Let $L_n$ denote the number of spaghetti loops at the end of this process (a loop is a chain of one or more spaghetti whose ends are tied to each other to form a cycle). Compute $E(L_n)$ and $V(L_n)$. Find a sequence of numbers $(b_n)_{n=1}^{\infty}$ such that

$$\frac{L_n}{b_n} \xrightarrow{P} 1,$$

if such a sequence exists.

28. Martians communicate in a binary language with two symbols, 0 and 1. A text of length $n$ symbols written in the Martian language looks like a sequence $X_1, X_2, \ldots, X_n$ of i.i.d. random symbols, each of which is 1 with probability $p$ and 0 with probability $1 - p$. Here, $p \in (0, 1)$ is a parameter (the “Martian bias”).

Define the entropy function $H(p)$ by

$$H(p) = -p \log_2 p - (1 - p) \log_2 (1 - p).$$

Prove the following result that effectively says that if $n$ is large, then with high probability a Martian text of length $n$ can be encoded into an ordinary (man-made) computer file of length approximately $n \cdot H(p)$ computer bits (note that if $p \neq 1/2$ then this is smaller than $n$, meaning that the text can be compressed by a linear factor):

**Theorem.** Let $X_1, X_2, X_3, \ldots$ be a sequence of i.i.d. Martian symbols (i.e., Bernoulli variables with bias $p$). Denote by $T_n = (X_1, \ldots, X_n)$ the Martian text comprising the first $n$ symbols. For any $\epsilon > 0$, if $n$ is sufficiently large, the set $\{0, 1\}^n$ of possible texts of length $n$ can be partitioned into two disjoint sets,

$$\{0, 1\}^n = A_n \cup B_n,$$

such that the following statements hold:

(a) $P(T_n \in B_n) < \epsilon$

(b) $2^{n(H(p)-\epsilon)} \leq |A_n| \leq 2^{n(H(p)+\epsilon)}$. 

103
Notes: The texts in $B_n$ can be thought of as the “exceptional sequences” – they are the Martian texts of length $n$ that are rarely observed. The texts in $A_n$ are called “typical sequences”. Because of the two-sided bounds the theorem gives on the number of typical sequences, it follows that we can encode them in a computer file of size approximately $nH(p)$ bits, provided we prepare in advance a “code” that translates the typical sequences to computer files of the appropriate size (this can be done algorithmically, for example by making a list of all the typical sequences sorted in lexicographic order, and matching them to successive binary strings of length $(H(p) + \epsilon)n)$.

**Hint.** To prove the theorem, let $P_n$ be the random variable given by

$$P_n = \prod_{k=1}^{n} \left( p^{X_k} (1 - p)^{1-X_k} \right).$$

Note that $P_n$ measures the probability of the sequence that was observed up to time $n$. (Somewhat unusually, in this problem the probability itself is thought of as a random variable). Try to represent $P_n$ in terms of cumulative sums of a sequence of i.i.d. random variables. Apply the Weak Law of Large Numbers to that sequence, and see where that gets you.

29. Prove the following one-sided version of Chebyshev’s inequality: For any r.v. $X$ and $t \geq 0$,

$$\mathbb{P}(X - \mathbb{E}X \geq t) \leq \frac{\sigma^2(X)}{t^2 + \sigma^2(X)}.$$

**Hint.** Assume without loss of generality that $\mathbb{E}X = 0$. For any $a > 0$, we have that $\mathbb{P}(X \geq t) \leq \mathbb{P}((X + a)^2 \geq (a + t)^2)$. Bound this using known methods and then look for the value of $a$ that gives the best bound.

30. Let $X_1, X_2, \ldots$ be a sequence of i.i.d. r.v.’s with distribution $\text{Exp}(1)$. Prove that

$$\mathbb{P} \left( \limsup_{n \to \infty} \frac{X_n}{\log n} = 1 \right) = 1.$$

31. Let $A = (X_{i,j})_{i,j=1}^{n}$ be a random $n \times n$ matrix of i.i.d. random signs (i.e., random variables such that $\mathbb{P}(X_{i,j} = -1) = \mathbb{P}(X_{i,j} = 1) = 1/2$). Compute $\text{Var}(\det(A))$.  

104
32. (a) Read, in Durrett’s book (p. 63 in the 3rd edition) or on Wikipedia, the statement and proof of Kronecker’s lemma.

(b) Deduce from this lemma, using results we learned in class, the following rate of convergence result for the Strong Law of Large Numbers in the case of a finite variance: If $X_1, X_2, \ldots$ is an i.i.d. sequence such that $\mathbb{E}X_1 = 0$, $\mathbb{V}(X_1) < \infty$, and $S_n = \sum_{k=1}^{n} X_k$, then for any $\epsilon > 0$,

$$\frac{S_n}{n^{1/2+\epsilon}} \xrightarrow{a.s.} 0.$$ 

Notes. When $X_1$ is a “random sign”, i.e., a random variable that takes the values $-1, +1$ with respective probabilities $1/2, 1/2$, the sequence of cumulative sums $(S_n)_{n=1}^{\infty}$ is often called a (symmetric) random walk on $\mathbb{Z}$, since it represents the trajectory of a walker starting from 0 and taking a sequence of independent jumps in a random (positive or negative) direction. An interesting question concerns the rate at which the random walk can drift away from its starting point. By the SLLN, it follows that almost surely, $S_n = o(n)$, so the distance of the random walk from the origin almost surely has sub-linear growth. By the exercise above, the stronger result $S_n = o(n^{1/2+\epsilon})$ also holds for all $\epsilon$. This is close to optimal, since by the Central Limit Theorem which we will discuss soon, one cannot hope to show that $S_n = o(n^{1/2})$. In fact, the “true” rate of growth is given by the following famous theorem, whose proof is a (somewhat complicated) elaboration on the techniques we have discussed.

**Theorem** (The Law of the Iterated Logarithm (A. Y. Khinchin, 1924)).

$$\mathbb{P}\left(\limsup_{n \to \infty} \frac{S_n}{\sqrt{2n \log \log n}} = 1\right) = 1.$$ 

Therefore, by symmetry, also

$$\mathbb{P}\left(\liminf_{n \to \infty} \frac{S_n}{\sqrt{2n \log \log n}} = -1\right) = 1.$$

It follows in particular that, almost surely, the random walk will cross the origin infinitely many times.

33. Prove that if $F$ and $(F_n)_{n=1}^{\infty}$ are distribution functions, $F$ is continuous, and for any $t \in \mathbb{R}$ we have $F_n(t) \to F(t)$ as $n \to \infty$, then the convergence is uniform in $t$. 

34. Let \( \varphi(x) = (2\pi)^{-1/2}e^{-x^2/2} \) be the standard normal density function.

(a) If \( X_1, X_2, \ldots \) are i.i.d. Poisson(1) random variables and \( S_n = \sum_{k=1}^{n} X_k \) (so \( S_n \sim \text{Poisson}(n) \)), show that if \( n \) is large and \( k \) is an integer such that \( k \approx n + x\sqrt{n} \) then

\[
P(S_n = k) \approx \frac{1}{\sqrt{n}} \varphi(x).
\]

**Hint.** Use the fact that \( \log(1 + u) = u - u^2/2 + O(u^3) \) as \( u \to 0 \).

(b) Find \( \lim_{n \to \infty} e^{-n} \sum_{k=0}^{n} \frac{n^k}{k!} \).

(c) If \( X_1, X_2, \ldots \) are i.i.d. Exp(1) random variables and denote \( S_n = \sum_{k=1}^{n} X_k \) (so \( S_n \sim \Gamma(n, 1) \)), \( \hat{S}_n = (S_n - n)/\sqrt{n} \). Show that if \( n \) is large and \( x \in \mathbb{R} \) is fixed then the density of \( \hat{S}_n \) satisfies

\[
f_{\hat{S}_n}(x) \approx \varphi(x).
\]

35. (a) Prove that if \( X, (X_n)_{n=1}^{\infty} \) are random variables such that \( X_n \to X \) in probability then \( X_n \Rightarrow X \).

(b) Prove that if \( X_n \Rightarrow c \) where \( c \in \mathbb{R} \) is a constant, then \( X_n \to c \) in probability.

(c) Prove that if \( Z, (X_n)_{n=1}^{\infty}, (Y_n)_{n=1}^{\infty} \) are random variables such that \( X_n \Rightarrow Z \) and \( X_n - Y_n \to 0 \) in probability, then \( Y_n \Rightarrow Z \).
36. (a) Let $X, (X_n)_{n=1}^\infty$ be integer-valued r.v.’s. Show that $X_n \implies X$ if and only if $P(X_n = k) \to P(X = k)$ for any $k \in \mathbb{Z}$.

(b) If $\lambda > 0$ is a fixed number, and for each $n$, $Z_n$ is a r.v. with distribution $\text{Binomial}(n, \lambda/n)$, show that $Z_n \implies \text{Poisson}(\lambda)$.

37. Let $f(x) = (2\pi)^{-1/2}e^{-x^2/2}$ be the density function of the standard normal distribution, and let $\Phi(x) = \int_x^\infty f(u) \, du$ be its c.d.f. Prove the inequalities

$$\frac{1}{x+1} f(x) \leq 1 - \Phi(x) \leq \frac{1}{x} f(x), \quad (x > 0).$$  \hspace{1cm} (21)

Note that for large $x$ this gives a very accurate two-sided bound for the tail of the normal distribution. In fact, it can be shown that

$$1 - \Phi(x) = f(x) \cdot \frac{1}{x + \frac{1}{x + \frac{1}{x + \frac{1}{x + \cdots}^2}}}$$

which gives a relatively efficient method of estimating $\Phi(x)$.

**Hint.** To prove the upper bound in (21), use the fact that for $t > x$ we have $e^{-t^2/2} \leq (t/x)e^{-t^2/2}$. For the lower bound, use the identity

$$\frac{d}{dx} \left( \frac{e^{-x^2/2}}{x} \right) = - \left( 1 + \frac{1}{x^2} \right) e^{-x^2/2}$$

to compute $\int_x^\infty (1+u^{-2})e^{-u^2/2} \, du$. On the other hand, show that this integral is bounded from above by $(1 + x^{-2}) \int_x^\infty e^{-u^2/2} \, du$.

38. (a) Let $X_1, X_2, \ldots$ be a sequence of independent r.v.’s that are uniformly distributed on $\{1, \ldots, n\}$. Define

$$T_n = \min\{k : X_k = X_m \text{ for some } m < k\}.$$

If the $X_j$’s represent the birthdays of some sequence of people on a planet in which the calendar year has $n$ days, then $T_n$ represents the number of people in the list who
have to declare their birthdays before two people are found to have the same birthday. Show that
\[ \mathbb{P}(T_n > k) = \prod_{m=1}^{k-1} \left(1 - \frac{m}{n}\right), \quad (k \geq 2), \]
and use this to prove that
\[ \frac{T_n}{\sqrt{n}} \Rightarrow F_{\text{birthday}}, \]
where \( F_{\text{birthday}} \) is the distribution function defined by
\[ F_{\text{birthday}}(x) = \begin{cases} 
0 & x < 0, \\
1 - e^{-x^2/2} & x \geq 0
\end{cases} \]
(note: this is not the same as the normal distribution!)

(b) Take \( n = 365 \). Assuming that the approximation \( F_{T_n/\sqrt{n}} \approx F_{\text{birthday}} \) is good for such a value of \( n \), estimate what is the minimal number of students that have to be put into a classroom so that the probability that two of them have the same birthday exceeds 50%.
(Ignore leap years, and assume for simplicity that birthdays are distributed uniformly throughout the year; in practice this is not entirely true.)

39. Consider the following two-step experiment: First, we choose a uniform random variable \( U \sim U(0, 1) \). Then, conditioned on the event \( U = u \), we perform a sequence of \( n \) coin tosses with bias \( u \), i.e., we have a sequence \( X_1, X_2, \ldots, X_n \) such that conditioned on the event \( U = u \), the \( X_k \)'s are independent and have distribution Binom(1, \( u \)). (Note: without this conditioning, the \( X_k \)'s are not independent!)

Let \( S_n = \sum_{k=1}^{n} X_k \). Assume that we know that \( S_n = k \), but don’t know the value of \( U \). What is our subjective estimate of the probability distribution of \( U \) given this information? Show that the conditional distribution of \( U \) given that \( S_n = k \) is the beta distribution \( \text{Beta}(k + 1, n - k + 1) \). In other words, show that
\[ \mathbb{P}(U \leq x \mid S_n = k) = \frac{1}{B(k, n - k)} \int_{0}^{x} u^k (1 - u)^{n-k} \, du, \quad (0 \leq x \leq 1). \]

Note: This problem has been whimsically suggested by Laplace in the 18th century as a way to estimate the probability that the sun will rise tomorrow, given the knowledge
that it has risen in the last \( n \) days. (Of course, this assumes the unlikely theological scenario whereby at the dawn of history, a \( U(0, 1) \) random number \( U \) was drawn, and that subsequently, every day an independent experiment was performed with probability \( U \) of success, such that if the experiment is successful then the sun rises.)

**Hint.** Use the following density version of the total probability formula: If \( A \) is an event and \( X \) is a random variable with density \( f_X \), then

\[
P(A) = \int_{\mathbb{R}} f_X(u)P(A \mid X = u) \, du.
\]

Note that we have not defined what it means to condition on a 0-probability event (this is a somewhat delicate subject that we will not discuss in this quarter) — but don’t worry about it, it is possible to use the formula in computations anyway and get results.

40. Let \( Z_1, Z_2, \ldots \) be a sequence of i.i.d. random variables with the standard normal \( N(0, 1) \) distribution. For each \( n \), define the random vector

\[
X_n = (X_{n,1}, \ldots, X_{n,n}) = \frac{1}{(\sum_{i=1}^{n} Z_i^2)^{1/2}}(Z_1, \ldots, Z_n)
\]

(a) The distribution of the random vector \( X_n \) is called the *uniform distribution on the \((n - 1)\)-dimensional sphere* \( S^{n-1} = \{ x \in \mathbb{R}^n : ||x|| = 1 \} \). Explain why this makes intuitive sense, and if possible explain rigorously what conditions this distribution satisfies that justifies describing it by this name.

(b) Show that \( \sqrt{n}X_{n,1} \Rightarrow N(0, 1) \) as \( n \to \infty \).

**Hint.** Use the law of large numbers.

(c) For each \( n \geq 1 \), find the density function of the coordinate \( X_{n,1} \). Optionally, use this to give an alternative solution to part (b) above.

**Hint.** Do it first for \( n = 2 \) and \( n = 3 \), and generalize using ideas from multivariate calculus. For \( n = 3 \), you should find that \( X_{3,1} \sim U[-1, 1] \), a geometric fact which was known to Archimedes.

41. Compute the characteristic functions for the following distributions.
(a) **Poisson distribution:** $X \sim \text{Poisson}(\lambda)$.

(b) **Geometric distribution:** $X \sim \text{Geom}(p)$ (assume a geometric that starts at 1).

(c) **Uniform distribution:** $X \sim U[a, b]$, and in particular $X \sim [-1, 1]$ which is especially symmetric and useful in applications.

(d) **Exponential distribution:** $X \sim \text{Exp}(\lambda)$.

(e) **Symmetrized exponential:** A r.v. $Z$ with density function $f_Z(x) = \frac{1}{2} e^{-|x|}$.

Note that this is the distribution of the exponential distribution after being “symmetrized” in either of two ways: (i) We showed that if $X, Y \sim \text{Exp}(1)$ are independent then $X - Y$ has density $\frac{1}{2} e^{-|x|}$; (ii) alternatively, it is the distribution of an “exponential variable with random sign”, namely $\varepsilon \cdot X$ where $X \sim \text{Exp}(1)$ and $\varepsilon$ is a random sign (same as the coin flip distribution mentioned above) that is independent of $X$.

42. (a) If $X$ is a r.v., show that $\text{Re}(\varphi_X)$ (the real part of $\varphi_X$) and $|\varphi_X|^2 = \varphi_X \overline{\varphi_X}$ are also characteristic functions (i.e., construct r.v.’s $Y$ and $Z$ such that $\varphi_Y(t) = \text{Re}(\varphi_X(t))$, $\varphi_Z(t) = |\varphi_X(t)|^2$).

(b) Show that $X$ is equal in distribution to $-X$ if and only if $\varphi_X$ is a real-valued function.

43. (a) Let $Z_1, Z_2, \ldots$ be a sequence of independent r.v.’s such that the random series $X = \sum_{n=1}^{\infty} Z_n$ converges a.s. Prove that

$$\varphi_X(t) = \prod_{n=1}^{\infty} \varphi_{Z_n}(t), \quad (t \in \mathbb{R}).$$

(b) Let $X$ be a uniform r.v. in $(0, 1)$, and let $Y_1, Y_2, \ldots$ be the (random) bits in its binary expansion, i.e. each $Y_n$ is either 0 or 1, and the equation

$$X = \sum_{n=1}^{\infty} \frac{Y_n}{2^n}$$

holds. Show that $Y_1, Y_2, \ldots$ are i.i.d. unbiased coin tosses (i.e., taking values 0, 1 with probabilities $1/2, 1/2$).
(c) Compute the characteristic function $\varphi_Z$ of $Z = 2X - 1$ (which is uniform in $(-1, 1)$). Use (22) to represent this in terms of the characteristic functions of the $Y_n$’s (note that the series (22) converges absolutely, so here there is no need to worry about almost sure convergence). Deduce the infinite product identity

$$\frac{\sin(t)}{t} = \prod_{n=1}^{\infty} \cos \left( \frac{t}{2^n} \right), \quad (t \in \mathbb{R}). \quad (23)$$

(d) Substitute $t = \pi/2$ in (23) to get the identity

$$\frac{2}{\pi} = \frac{\sqrt{2}}{2} \cdot \frac{\sqrt{2 + \sqrt{2}}}{2} \cdot \frac{\sqrt{2 + \sqrt{2 + \sqrt{2}}}}{2} \cdot \ldots$$

44. Let $X$ be a r.v. From the inversion formula, it follows without much difficulty (see p. 95 in Durrett’s book, 3rd or 4th eds.), that if $\varphi_X$ is integrable, then $X$ has a density $f_X$, and the density and characteristic function are related by

$$\varphi_X(t) = \int_{-\infty}^{\infty} f_X(x) e^{itx} \, dx,$$

$$f_X(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \varphi_X(t) e^{-itx} \, dt$$

(this shows the duality between the Fourier transform and its inverse). Use this and the answer to a previous exercise to conclude that if $X$ is a r.v. with the Cauchy distribution (i.e., $X$ has density $f_X(x) = 1/\pi (1 + x^2)$) then its characteristic function is given by

$$\varphi_X(t) = e^{-|t|}.$$ 

Deduce from this that if $X, Y$ are independent Cauchy r.v.’s then any weighted average $\lambda X + (1 - \lambda)Y$, where $0 \leq \lambda \leq 1$, is also a Cauchy r.v. (As a special case, it follows by induction that if $X_1, \ldots, X_n$ are i.i.d. Cauchy r.v.’s, then their average $(X_1 + \ldots + X_n)/n$ is also a Cauchy r.v., which was a claim we made without proof earlier in the course.)
