

# Lecture 14 : Continuous Wavelet Transf. II

Note Title

2/18/2014

In order to discuss the so-called **analytic wavelets**, we need to know a bit about the concept of **analytic signals**.

→ better than real-valued wavelets in  
1) capturing **phase** info; 2) time-freq. tiling.

## ★ Analytic Signal

Def.  $f_a \in L^2(\mathbb{R})$  is said to be **analytic**  
if  $\hat{f}_a(\xi) = 0 \quad \forall \xi < 0$ .

$f_a(x) \in \mathbb{C}$ , but  $\exists$  a special relationship  
between  $\text{Re}(f_a)$  &  $\text{Im}(f_a)$ :

$$\begin{aligned} \text{Im}(f_a)(x) &= \frac{1}{\pi} \int_{-\infty}^{\infty} \frac{\text{Re}(f_a)(y)}{x-y} dy \\ &= \frac{1}{\pi x} * \text{Re}(f_a) = \mathcal{H}[\text{Re}(f_a)](x) \end{aligned}$$

The Hilbert transform on  $\mathbb{R}$

Let  $f(x) = \text{Re}(f_a)(x)$ . Then,

$$f_a(x) = f(x) + i \mathcal{H}f(x)$$

$$\begin{aligned} \hat{f}_a(\xi) &= \hat{f}(\xi) + i \left( \frac{1}{\pi x} \right) \cdot \hat{f}(\xi) = \hat{f}(\xi) + i (-i \text{sgn } \xi) \hat{f}(\xi) \\ &= \hat{f}(\xi) (1 + \text{sgn } \xi) \end{aligned}$$

$$= \hat{f}(\xi) (1 + \text{sgn } \xi) = \begin{cases} 2\hat{f}(\xi) & \text{if } \xi \geq 0 \\ 0 & \text{if } \xi < 0. \end{cases}$$

Ex.  $f(x) = a \cos(2\pi \xi_0 x + \theta)$ ,  $a, \theta \in \mathbb{R}$ ,

$$\Rightarrow f_a(x) = ae^{i(2\pi \xi_0 x + \theta)}, \quad \xi_0 > 0.$$

an easy exercise!

Def. An **analytic wavelet fcn**  $\psi \in L^2(\mathbb{R})$  is a wavelet that is also an analytic signal, i.e., it's  $\mathbb{C}$ -valued and satisfies

- basic prop.  $\left\{ \begin{array}{l} \cdot \int_{-\infty}^{\infty} \psi(x) dx = 0 \text{ (i.e., } \hat{\psi}(0) = 0) \\ \cdot \|\psi\|_2 = 1 \\ \cdot \psi(x) \text{ is centered around } x=0 \end{array} \right.$

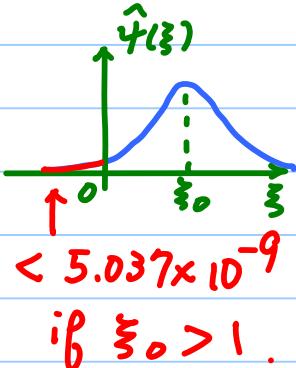

admissibility cond.  $\int_{-\infty}^{\infty} \frac{|\hat{\psi}(\xi)|^2}{|\xi|} d\xi < +\infty$  (the adm. cond.)

analyticity  $\cdot \hat{\psi}(\xi) = 0 \text{ for } \xi < 0 \text{ (i.e., } \xi \leq 0)$

### Examples

- Morlet wavelet

$$\begin{aligned} \psi(x) &= \pi^{-1/4} e^{2\pi i \xi_0 x} e^{-x^2/2} \\ \rightarrow \hat{\psi}(\xi) &= \sqrt{2} \pi^{-1/4} e^{-2\pi^2(\xi - \xi_0)^2} \\ \rightarrow \text{Not exactly analytic, but close.} &\quad \text{if } \xi_0 > 1. \end{aligned}$$

- Generalized Morse wavelet (family)

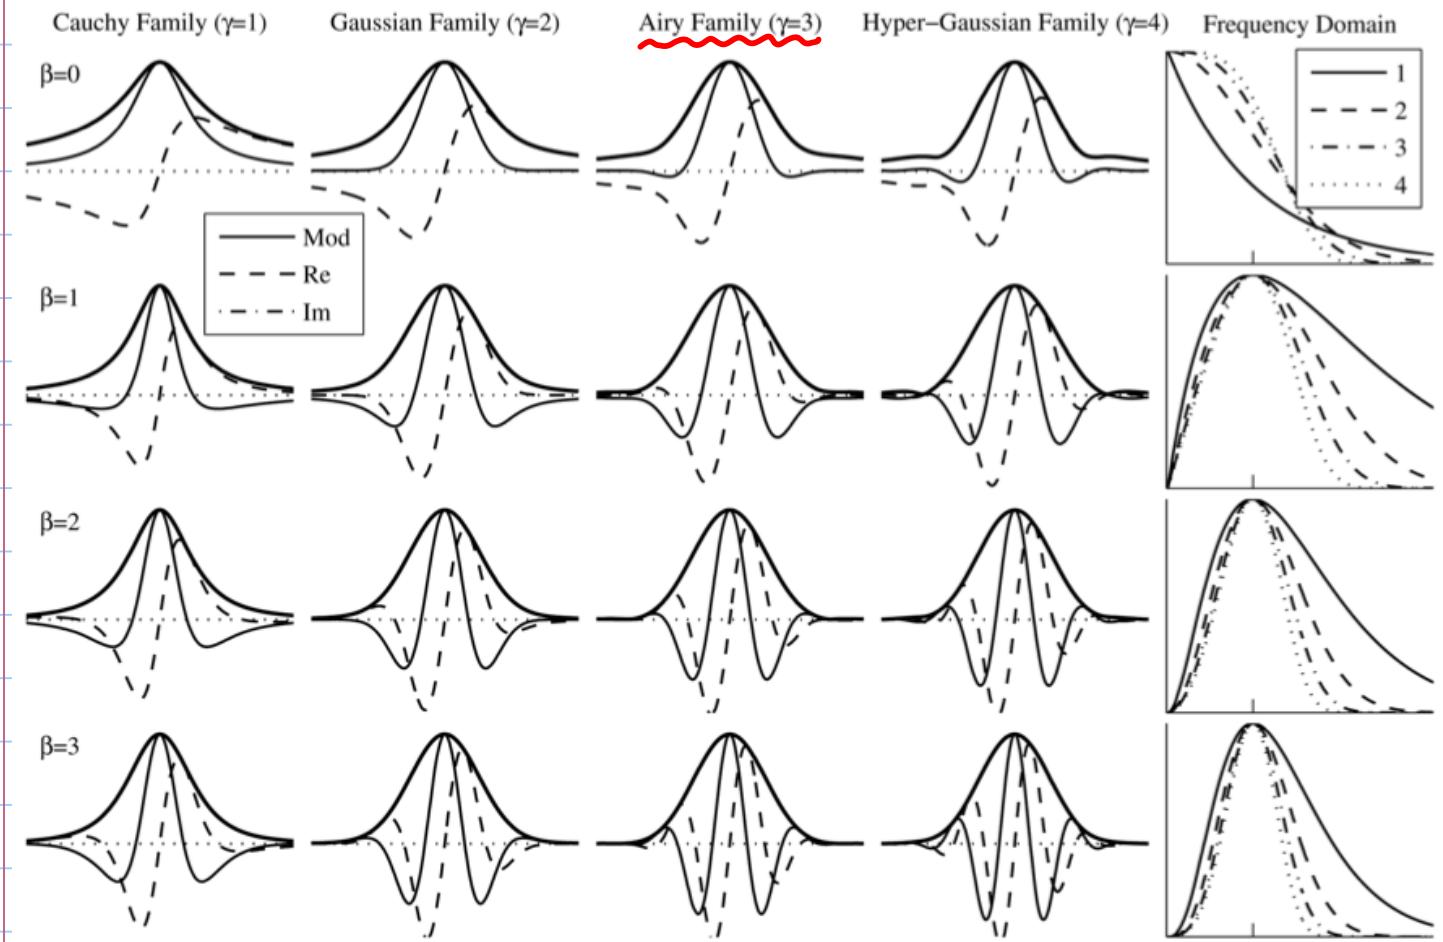

$$\hat{\psi}(\xi) = \chi_{[0, \infty)}(\xi) C_{\beta, \gamma} \xi^{\beta} e^{-(2\pi\xi)^{\gamma}}, \quad \beta, \gamma > 0$$

$C_{\beta, \gamma}$  is a normalization const.

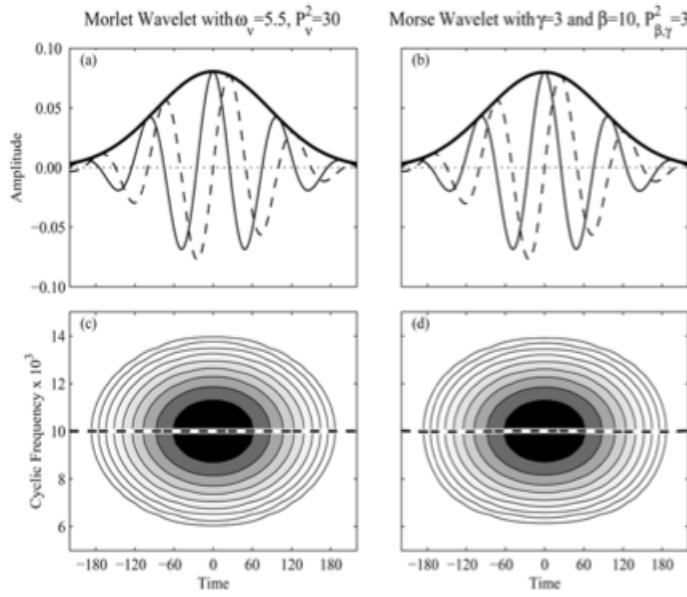

$\rightarrow$  Exactly analytic!

$\rightarrow$  This family includes many of the previously proposed analytic wavelets e.g., Bessel, Cauchy, analytic version of Mexican hat, Shannon.

$\rightarrow$   $\gamma = 3$  case closely approximates Morlet.

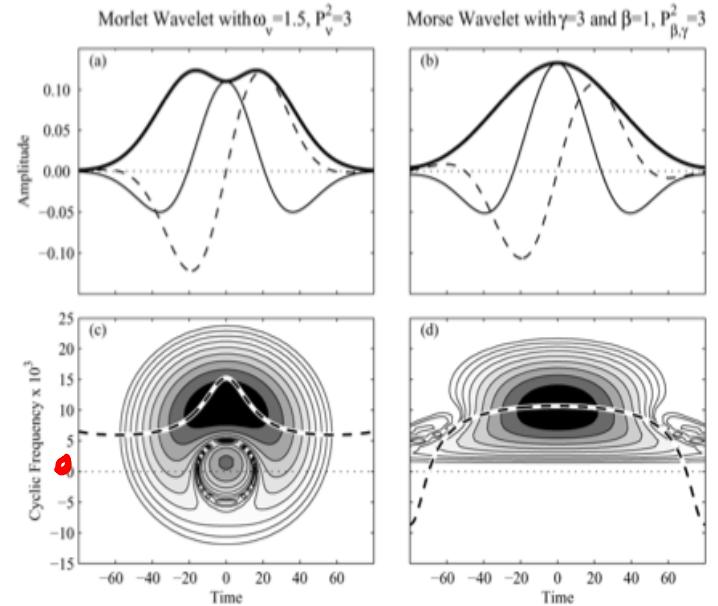

*Morlet vs Morse*

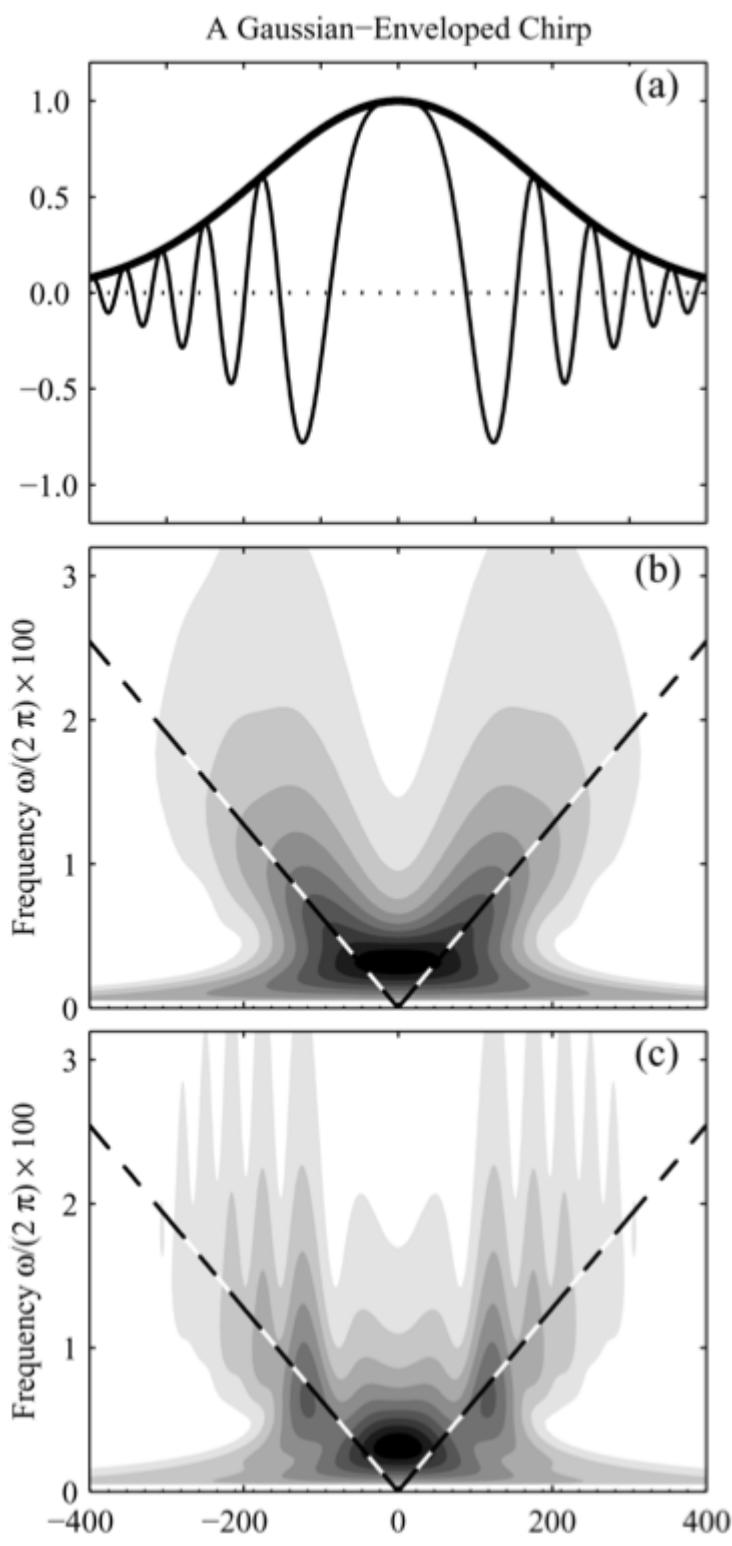

$\leftarrow$  long  $\rightarrow$   $\leftarrow$  long  $\rightarrow$

*Morlet vs Morse*

$\leftarrow$  short  $\rightarrow$   $\leftarrow$  short  $\rightarrow$

Exact analyticity  
is important for  
signal analysis;  
non-analyticity  
leads to interference  
and artifacts in  
the time-freq. plane,  
and consequently to  
erroneous amplitude  
& phase estimates.

Morse

Morlet

## ★ Heisenberg Box of analytic wavelets

$$Wf(a, b) = \langle f, \psi_{a,b} \rangle = \int f(x) \frac{1}{\sqrt{a}} \psi\left(\frac{x-b}{a}\right) dx$$

$$\text{Suppose } m_x(\psi) = \int_{-\infty}^{\infty} x |\psi(x)|^2 dx = 0.$$

$$\begin{aligned} \text{Then } m_x(\psi_{a,b}) &= \int_{-\infty}^{\infty} x \frac{1}{a} |\psi\left(\frac{x-b}{a}\right)|^2 dx \\ \frac{x-b}{a} = y &\quad \downarrow \\ &= \int_{-\infty}^{\infty} (ay + b) |\psi(y)|^2 dy \\ &= b \int_{-\infty}^{\infty} |\psi(y)|^2 dy = b \quad \checkmark \end{aligned}$$

$$\begin{aligned} \sigma_x^2(\psi_{a,b}) &= \int_{-\infty}^{\infty} (x - b)^2 \frac{1}{a} |\psi\left(\frac{x-b}{a}\right)|^2 dy \\ &= \int_{-\infty}^{\infty} a^2 y^2 |\psi(y)|^2 dy = a^2 \sigma_x^2(\psi) \end{aligned}$$

Now, how about these in the freq. domain?

$$m_{\xi}(\psi) = \int_{-\infty}^{\infty} \xi |\hat{\psi}(\xi)|^2 d\xi = \underbrace{\int_{-\infty}^{\infty} \xi |\hat{\psi}(\xi)|^2 d\xi}_{\text{the center freq. of } \psi}$$

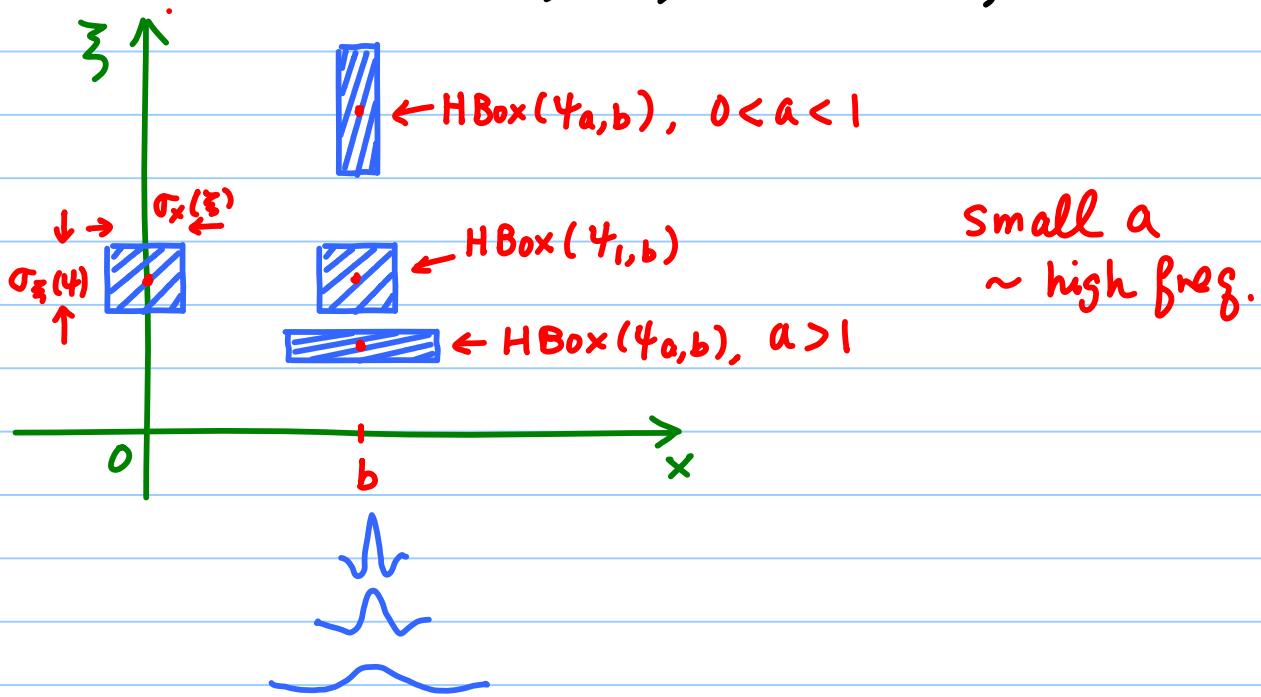

$$\begin{aligned} m_{\xi}(\psi_{a,b}) &= \int_{-\infty}^{\infty} \xi |\hat{\psi}_{a,b}(\xi)|^2 d\xi \\ &= \int_{-\infty}^{\infty} \xi a |\hat{\psi}(a\xi)|^2 d\xi \\ &= \frac{1}{a} \int_0^{\infty} \eta |\hat{\psi}(\eta)|^2 d\eta = \frac{m_{\xi}(\psi)}{a} \end{aligned}$$

$$\begin{aligned} \sigma_{\xi}^2(\psi_{a,b}) &= \int_{-\infty}^{\infty} (\xi - \frac{m_{\xi}}{a})^2 |\hat{\psi}_{a,b}(\xi)|^2 d\xi \\ &= \int_{-\infty}^{\infty} (\xi - \frac{m_{\xi}}{a})^2 a \cdot |\hat{\psi}(a\xi)|^2 d\xi \end{aligned}$$

$$\begin{aligned}
 &= \frac{1}{a^2} \int_0^\infty (\zeta - m_\xi(4))^2 |\hat{f}(\zeta)|^2 d\zeta \\
 &= \frac{\sigma_\xi^2(4)}{a^2}
 \end{aligned}$$

### Summary

$$\left\{
 \begin{array}{l}
 m_x(4_{a,b}) = b, \quad \sigma_x(4_{a,b}) = a \sigma_x(4) \\
 m_\xi(4_{a,b}) = m_\xi(4)/a, \quad \sigma_\xi(4_{a,b}) = \sigma_\xi(4)/a
 \end{array}
 \right.$$

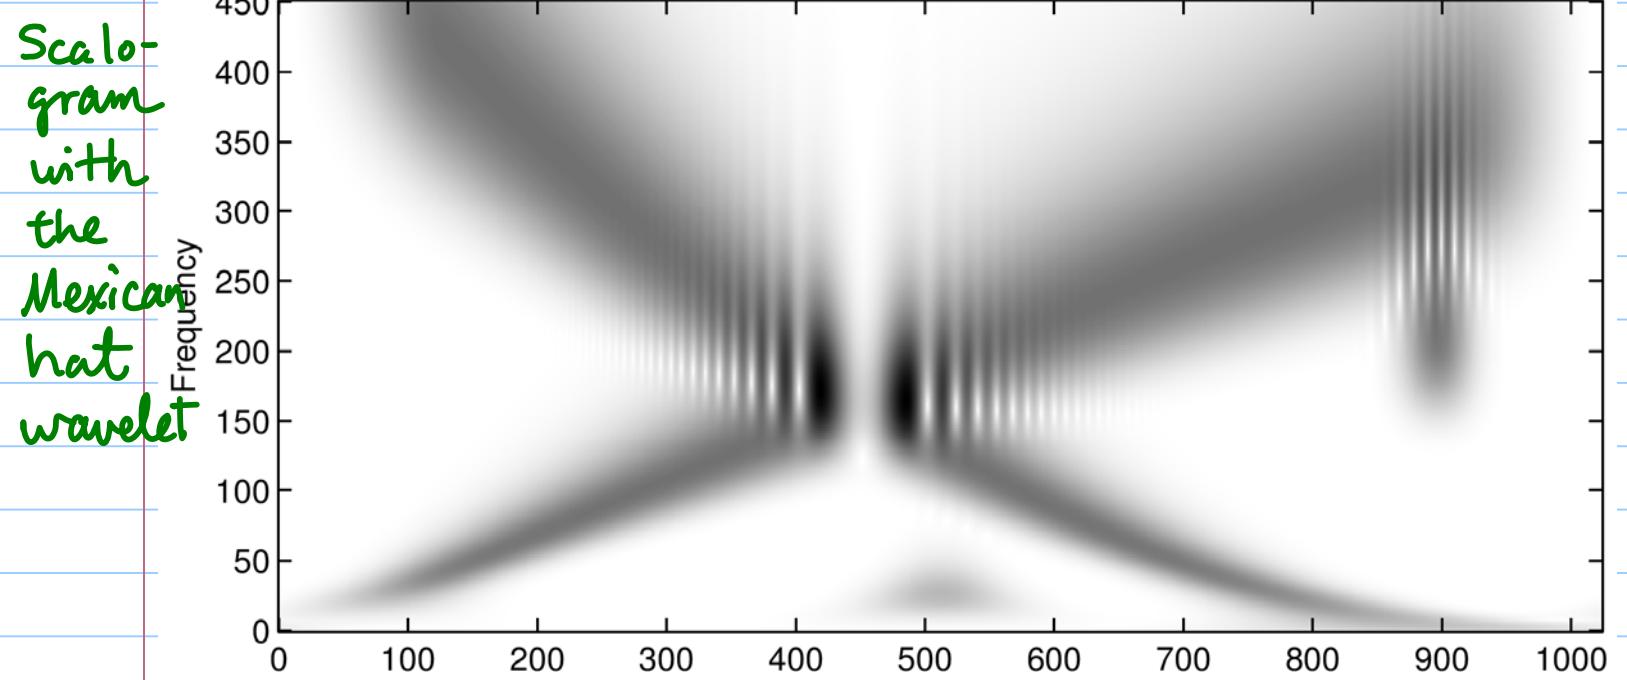

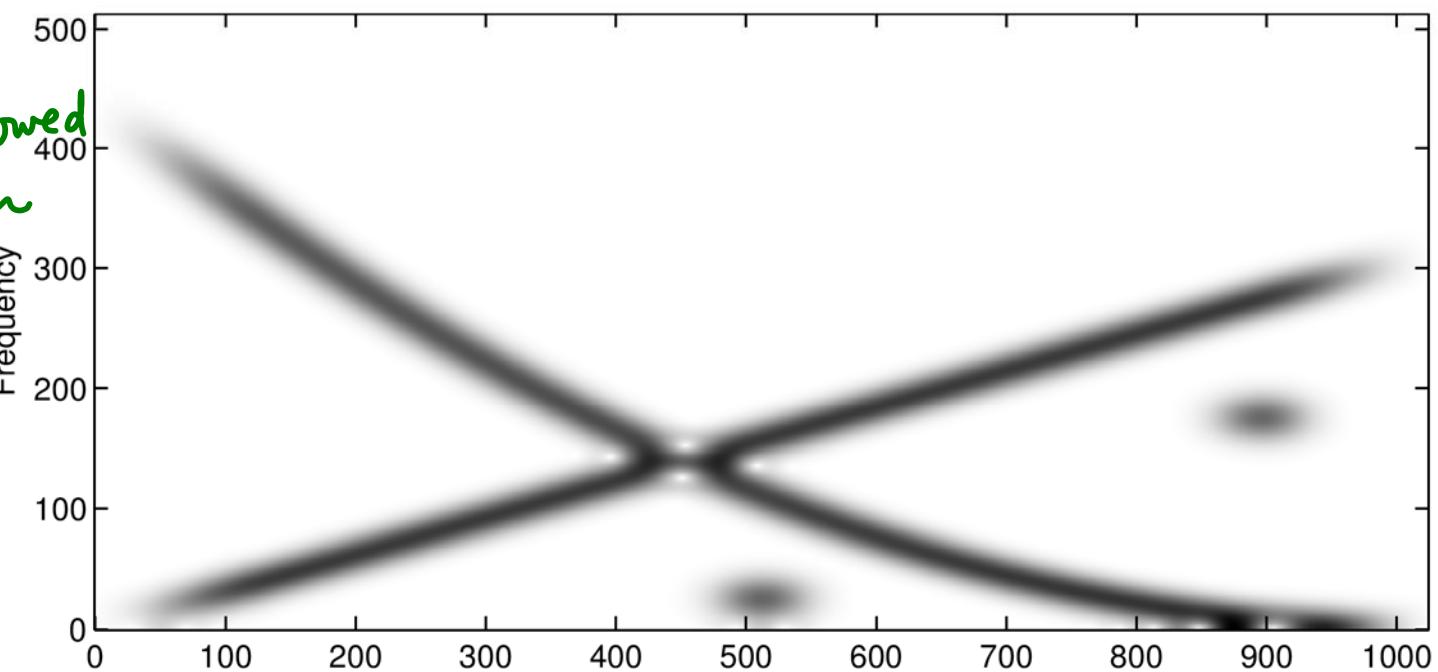

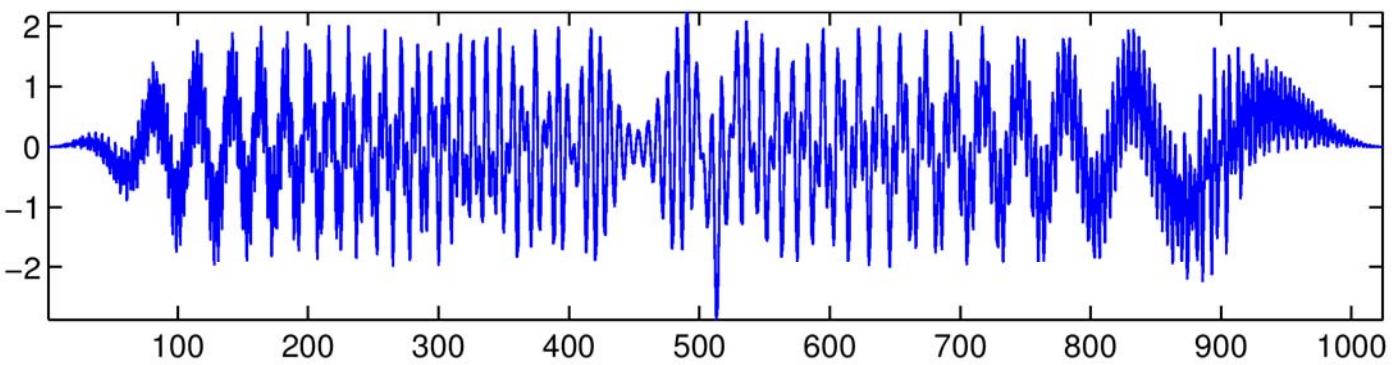

We can now compute the local time-freq. energy density of  $f \in L^2(\mathbb{R})$  as

$$P_W f(x, \xi) := |Wf(a, x)|^2 = |Wf\left(\frac{m_\xi}{\xi}, x\right)|^2$$

$$\downarrow \xi = \frac{m_\xi}{a} \uparrow$$

This 2D plot is called the **Scalogram** of  $f$ .  
Warning:  $|Wf(a, b)|^2$  is sometimes called the scalogram too.

## Remarks :

- (1) Using the **truly analytic wavelets** (e.g. generalized Morse wavelets), the scalogram should become more focussed & less artifacts.
- (2)  $\exists$  a sharpening technique called "**synchrosqueezing**" wavelet transform  
 $\Rightarrow$  A possible final project (C)
- (3)  $\mathbb{C}$ -valued wavelets have gained popularity among discrete wavelet transforms!  $\Rightarrow$  The Dual Tree CWT.
- (4) What is the extension of "analyticity" in higher dimensions?  
 $\Rightarrow$  **monogenicity**
