to N = K can be deduced from (27) to be

According to § 7, patterns that are in the list (26) but not in (29) correspond to hanging keyblocks—in this case all three do. Likewise, all three patterns in (27), and hence also those in (28), also correspond to hanging keyblocks.

Finally, we observe that if the excavation is below, rather than above, the sloping excavation face, so that (26) is replaced by the list

then there is no overlap with (27), so that in this case no blocks that intersect the corner are keyblocks. The pattern U L L L is the only one from (30) that is not in (29), and hence it represents the only hanging keyblock in this case.

Appendix—Statement of Tucker's Theorem of the Alternative. For the convenience of readers we give a statement of Tucker's Theorem of the Alternative, as presented in [3, p. 29].

Let B, C and D be given matrices, with B being nonvacuous. Then either the system $Bx \ge 0$ but not all zero, $Cx \ge 0$, Dx = 0 has a solution x or the system $\lambda'B + \mu'C + \nu'D = 0$, $\lambda > 0$, $\mu \ge 0$ has a solution λ , μ , ν , but never both.

This theorem was first given by Tucker in [7].

Acknowledgments. The authors are grateful to Messrs W. N. Merten, W. L. van Heerden and F. A. Vreede of the National Mechanical Engineering Research Institute of the CSIR, Pretoria for stimulating discussions on the practical importance of the Shi-Goodman work, and for prompting our interest in in the keyblock identification problem.

HARD ENUMERATION PROBLEMS IN GEOMETRY AND COMBINATORICS*

NATHAN LINIALT

Abstract. A number of natural enumeration problems in geometry and combinatorics are shown to be complete in the class *P introduced by Valiant. Among others this is established for the numeration of vertices and of facets of a polytope, acyclic orientations of a graph and satisfying assignments of implicative boolean formulas.

Key words. #P, polytopes, partial orders, acylic orientations

Introduction. This article contains a contribution to the theory of hard enumeration problems. The foundations of this area were laid by Valiant [Va1], [Va2] who defines the class #P of enumeration problems and the subclass of problems complete in #P. The most interesting of his results is the #P completeness of computing permanent of 0-1 matrices. This problem can also be stated as the problem of enumerating perfect matchings in bipartite graphs. While deciding whether a bipartite graph has a perfect matching can be done in polynomial time [H] the enumeration problem is #P-complete matching can be done in polynomial time [H] the enumeration problem is #P-complete matching can be done in polynomial time [H] the enumeration problem is #P-complete matching can be done in polynomial time [H] the enumeration problem is #P-complete matching can be done in polynomial time [H] the enumeration problem is #P-complete matching can be done in polynomial time [H] the enumeration problem is #P-complete matching can be done in polynomial time [H] the enumeration problem is #P-complete matching can be done in polynomial time [H] the enumeration problem is #P-complete matching can be done in polynomial time [H] the enumeration problem is #P-complete matching can be done in polynomial time [H] the enumeration problem is #P-complete matching can be done in polynomial time [H] the enumeration problem is #P-complete matching can be done in polynomial time [H] the enumeration problem is #P-complete matching can be done in polynomial time [H] the enumeration problem is #P-complete matching can be done in polynomial time [H] the enumeration problem is #P-complete matching can be done in polynomial time [H] the enumeration problem can also be accepted to the can be done in polynomial time [H] the enumeration problem can also be accepted to the can be done in polynomial time [H] the enumeration problem can also be accepted to the can be done in polynomial time [H] the enumeration problem can also be accepted to the can be done in polyn

Valiant's pioneering work was continued by a recent article of Provan and Bal [PB] who prove the #P-completeness of a number of natural enumeration problems. With every enumeration problem there is an associated decision problem. Instead of a sking for the number of objects in question we ask whether this number is zero of not. The decision problem associated with the computation of the permanent function is the question whether a given bipartite graph has a perfect matching. While this decision is solvable in polynomial time, it is by no means trivial. Notice, however, that for many of the problems discussed in [PB] the situation is even more extreme: Consider for example the problem of enumerating independent sets in a bipartite graph, the decision problem associated with this enumeration problem is trivial: Every graph has an independent set of vertices. So an enumeration problem can be #P-complete eve if the existence problem is trivial.

This article assumes acquaintance with the theory of #P-completeness as presente in [Va1], [PB] and [GJ]. Our purpose is to present a number of natural enumeratio problems which belong to the class of #P-complete problems. The problems ar geometric, combinatorial and from propositional calculus.

Here is our main theorem:

THEOREM. The following enumeration problems are #P-complete.

- (1) Vertices in a polytope.
- Input: A system of linear inequalities $Ax \le b$ defining a polytope $P \subseteq \mathbb{R}^n$. Output: The number of vertices of P.
- (2) d-dimensional faces of a polytope (fixed d).

Input: As in (1).

Output: The number of d-dimensional faces of P.

^{*} Received by the editors December 10, 1984.

[†] Institute of Mathematics and Computer Science, Hebrew University, Jerusalem 91904, Israel

(3) Facets of a polytope.

Input: A finite set of points in R".

Output: The number of facets ((n-1)-dimensional faces) of P.

(4) Components of slotted space.

Input: A set $\{H_i|i\in I\}$ of hyperplanes in \mathbb{R}^i

Output: The number of connected components of $\{\mathbb{R}^n \setminus \bigcup H_i | i \in I\}$.

(5) Acyclic orientations of a graph.

input: A graph G = (V, E)

Output: The number of orientations of G with no directed circuit.

(6) 3-colorings of a bipartite graph.

Input: A bipartite graph G = (A, B, E).

Output: The number of ways to properly color G with 3 colors.

(7) Satisfying assignments of an implicative Boolean formula.

 $\bigwedge_{i=1}(x_{i1}\vee \bar{X}_{i2}).$ Input: A Boolean formula B on variables x_1, \dots, x_n of the form

Output: Number of truth assignments for x_1, \dots, x_n which makes B true.

Given a poset (P, \ge) with P = [n] we associate with P a polytope B = B(P) in \mathbb{R}^n as Proof: (1) We use the fact from [PB] that enumerating order ideals is #P-complete.

$$B = \{x \in \mathbb{R}^n | 1 \ge x_i \ge 0, x_i > x_j \text{ if } i \ge j \text{ in } P\}.$$

(See [St2], [Li], [KS] where use is made of this polytope.)

correspondence between vertices and ideals is as follows: $\alpha + \varepsilon$ or by $\alpha - \varepsilon$ we will get a point of B. This implies that x is not a vertex of B. The some $0 < x_i < 1$. If $\alpha = \max\{x_j | 0 < x_j < 1\}$, then by replacing all coordinates $x_j = \alpha$ by of (P, \ge) . First we prove that all vertices of B have 0-1 coordinates. Let $x \in B$ have We claim that the vertices of B are in 1:1 correspondence with the order ideals

$$x \in \text{vert}(B) \leftrightarrow S = \{1 \le j \le n | x_j = 0\}.$$

It is easily verified that S is an ideal and that this correspondence is bijective.

faces of a polytope K. Consider r-fold pyramids P, with K as basis. In [Gru, p. 55] (2) Suppose that for some fixed d we can find $f_d(K)$ the number of d-dimensional

$$f_d(P_r) = \sum_{i} {r \choose i} f_{d-i}(K).$$

of equations in unknown If we write (*) for $r=0,\cdots,d$ and have all $f_d(P_r)$ evaluated, then we obtain a system

$$f_0(K), \cdots, f_k(K).$$

of vertices of K is #P-complete by (1), our claim follows. and $f_0(K)$ can be determined in polynomial time. Since evaluating $f_0(K)$ = the number This system of equations has a triangular matrix and so they can be solved successively

(3) This is just the dual of (1): See [Gru, p. 46] for polytope duality.

(5) The proof here is based on two observations.

its chromatic polynomial. Then $(-1)^n P(G,-1)$ equals the number of acyclic orientations PROPOSITION [St1]. Let G = (V, E) be a graph with n vertices and let $P(G, \lambda)$ be

> $G=(V_1,E_1),\ H=(V_2,E_2)$ where $V_1\cap V_2=\varnothing$. The join G+H has $V_1\cup V_2$ as its vertex For the other observation we have to define the operation of join of two graphs

 $E_1 \cup E_2 \cup \{[x,y] | x \in V_1, y \in V_2\}$

as its edge set. The following observation is immediate.

PROPOSITION. $P(G+K,\lambda) = \lambda(\lambda-1), \cdots, (\lambda-t+1)P(G,\lambda-t)$.

values of $P(G+K_n-1)$ for $i=1,\dots,n$, that means we can calculate the integers orientations is equivalent to computing P(G,-1) for the graph. But if we have the Now we can combine these two facts as follows. Being able to enumerate acyclic

$$P(G,-j)$$
 $(n+1 \ge j \ge 2)$.

reduction to coloring is parsimonious [GJ, p. 169]. $P(G,\lambda)$, the chromatic polynomial of G. This is a #P-complete problem because the But P is a monic polynomial of degree n so from these numbers we can compute

*P-complete and on the following result of Greene. $H_{ij} \subseteq \mathbb{R}^n$ is the hyperplane given (4) The proof here makes use of (5) that enumerating acyclic orientations is

by $\{x \in \mathbb{R}^n | x_i = x_j\}$. PROPOSITION [Gre]. Let G = (V, E) be a graph on n vertices and consider

$$S(G) = \mathbb{R}^n \setminus \bigcup H_{\theta}$$

where the union is over all i, j such that $[i,j] \in E$. The number of connected component

find I(G) the number of independent sets. Consider a graph H which is obtained b in bipartite graphs [PB]. Let G = (A, B, E) be a partite graph for which we want to of S(G) equals the number of acyclic orientations of G. defined by the set of vertices colored 3. This can be any independent set of G and s Suppose w. l.o.g. that a, b are colored 1, 2 respectively. The 3-coloring is now uniquel all vertices of $A \cup \{a\}$. Now let us compute $\chi(H,3)$, the number of 3-colorings of Hadding two new vertices a, b with a being adjacent to all vertices in $B \cup \{b\}$ and b t (6) We base this proof on the #P-completeness of enumerating independent set

$$\chi(H,3)=6I(G).$$

 (P, \ge) be a poset with $P = \{p_1, \dots, p_n\}$. Associate with it the Boolean expression This proves the #P-completeness of computing $\chi(H, 3)$. (7) This follows from #P-completeness of enumerating ideals in posets [PB]: L

$$B = {\scriptstyle \wedge} \{x_i \vee \bar{x}_j | p_j > p_i \text{ in } P\}.$$

assignment satisfying B is an ideal in (P, \cong) and that all ideals are obtained in this wa It is fairly easy to verify that the set of x_i which are assigned a true value in an

then f(x) < f(y). Consider the problem: (P, \ge) a linear extension is a 1:1 mapping $f: P \to \{1, \dots, |P|\}$ such that if x < y in Let us mention in closing a most intriguing problem in this field: For a pos

Enumeration of linear extensions.

Output: L(P), the number of linear extensions of (P, \leq) . Input: A poset (P, \cong) .

of our main theorem. We quote without proof of the following fact from [Li]: this we remind the reader about the polytope B(P) which was used in proving part computing the volume of a convex polytope is a hard computational problem. To s A proof of this conjecture will provide a first explicit statement to the effect th Conjecture. The enumeration of linear extensions is a #P-complete problem.

PROPOSITION. For a poset (P, \geqq) on |P| = p elements L(P) the number of linear extensions of P satisfies

$$L(P) = p! \text{vol}(B(P)).$$

The connection between the #P-completeness of enumerating linear extensions and the complexity of evaluating the volume of a convex polytope is now clear.

Let us also comment about the relationship between the number of linear extensions of a poset and enumerating order ideals. We use I(P) to denote the number of ideals in the poset P. For posets P, Q we define their product $P \times Q$ to be a partial order on the cartesian product of P and Q with $(x_1, y_1) \ge (x_2, y_2)$ if $x_1 \ge x_2$ in P and $y_1 \ge y_2$ in Q. A mapping $f: P \to Q$ is order preserving if $x \ge y$ in P implies $f(x) \ge f(y)$ in Q.

PROPOSITION. Let (P, \geq) be a poset and let C_t be the chain on t elements. Then $I(P \times C_t)$ equals the number of order preserving maps $f: P \to \{0, 1, \dots, t\}$.

Proof. With an ideal $J \subseteq P$ we associate a function $f: P \to \{0, \dots, t\}$ as follows: For every $x \in P$ there is unique $t \geqq j \geqq 0$ such that $(x, j) \in J$ and $(x, j - 1) \not\in J$. Let f(x) = t - j for that value j. Since J is an ideal, f is well defined and easily seen to be order preserving. It is also a routine matter verifying that this correspondence is bijective.

Now we come to the expression for the number of linear extensions of a poset. Theorem. For a poset (P, \geq) on |P| = n elements, the number of linear extensions L(P) satisfies

$$L(P) = I(P \times C_{n-1}) - nI(P \times C_{n-2}) + \binom{n}{2}I(P \times C_{n-3})$$
$$-+ \cdots \pm \binom{n}{n-2}I(P \times C_1) \mp \binom{n}{n-1}.$$

Proof. This follows from the previous proposition and Inclusion-Exclusion. Classify order preserving maps $f: P \to \{0, \dots, n-1\}$ according to their range. There are $I(P \times C_{n-1})$ such mappings altogether. Say f has property $t(n-1 \ge t \ge 0)$ if t is not in the range of f. L(P) is the number of order preserving maps which are onto, i.e., have no property and there are

$$\binom{n}{j}I(P+C_{n-j-1})$$

maps having a given set of j properties
