**Previous Symposia and Proceedings** 739
Preface

It is our great privilege and honor to present the proceedings of the 18th International Symposium on Transportation and Traffic Theory (ISTTT), held at The Hong Kong Polytechnic University in Hong Kong, China on 16-18 July 2009. The 18th ISTTT is jointly organized by the Hong Kong Society for Transportation Studies and Department of Civil and Structural Engineering of The Hong Kong Polytechnic University.

The ISTTT series is the main gathering for the world’s transportation and traffic theorists, and those who are interested in contributing to or gaining a deep understanding of traffic and transportation phenomena in order to better plan, design and manage the transportation system. Although it embraces a wide range of topics, from traffic flow theories and demand modeling to road safety and logistics and supply chain modeling, the ISTTT is hallmarkmed by its intellectual innovation, research and development excellence in the treatment of real-world transportation and traffic problems. The ISTTT prides itself in the extremely high quality of its proceedings. Previous ISTTT conferences were held in Warren, Michigan (1959), London (1963), New York (1965), Karlsruhe (1968), Berkeley, California (1971), Sydney (1974), Kyoto (1977), Toronto (1981), Delft (1984), Cambridge, Massachusetts (1987), Yokohama (1990), Berkeley, California (1993), Lyon (1996), Jerusalem (1999), Adelaide (2002), College Park, Maryland (2005), and London (2007).

This 18th ISTTT celebrates the 50th Anniversary of this premier conference series. The first Symposium, organized by Professor Robert Herman, was held on 7-8 December 1959. A total of 15 papers were presented in the 1st Symposium. The scope of this Symposium series has since broadened, from the Symposium on the Theory of Traffic Flow to the International Symposium on Transportation and Traffic Theory. The ISTTT has also grown in size, but is still limited to around 35 papers. The rationale is, as was since the 1st Symposium, to allow ample time for presentation and informal discussion. Indeed, this time, in celebrating the 50th Anniversary of this tradition, we have arranged roundtable discussions to further enhance the interactions among researchers, scientists, and practitioners. We hope to have an opportunity to reminisce advances made in the past, and to outline important, uncharted territories. In reviewing the outline of the 1st Symposium, we were awed by the foresights of the researchers then, addressing research topics such as traffic control, distribution of traffic on a network and that of households and workplaces, clustering tendency of vehicular traffic, modeling traffic via stochastic processes, and simulation of bottlenecks, etc. These topics appear as fresh today as they were posed 50 years ago, despite much progress having been made. Transportation and traffic theories renew themselves as technology advances, as human activities are re-organized, and as scarce resources become gradually depleted, etc, representing our best effort at the time to understand and
hence manage the needs and consequences of connecting activities, goods, and people. From this vantage point, we are confident that the best years for ISTTT are yet to come in the future.

It is timely to organize the 18th ISTTT in Hong Kong, as the thrust of transportation infrastructure development has emerged strongly in Asia. Indeed, many parts of Asia are currently undertaking extensive transportation infrastructure programs. Hong Kong, for example, will initiate 10 major infrastructure projects with an investment of about HK$250 billion (roughly US$32 billion), in which 6 are transportation projects, including 4 railway and 2 highway infrastructure projects. These transportation infrastructures will bring about an economic benefit of more than HK$100 billion (roughly US$12 billion) annually, amounting to some 7% of the GDP of Hong Kong in 2006. This points to the imminent demand of high caliber transportation and traffic planners and engineers for the planning, design, management and operation of the transportation systems. The 18th ISTTT offers an excellent platform to elevate the role of transportation and traffic theories for transportation infrastructure planning and operations.

Special thanks are given to Members of the International Advisory Committee (IAC) and the local organizing committee for reviewing the extended abstracts and then full paper submissions, especially under the short review time requested of them. Our particular appreciation is extended to the referees who have contributed their considerable time and effort to the two-tier review process. With their dedicated support, each paper submission received at least three reviews, typically four to five, sometimes up to six reviews. Given the extremely high selectivity, we have tried our very best to ensure that each paper submission received a sufficient number of reviews to evaluate its merit. In reality, the tight constraint on the number of papers to be accepted for this Symposium have forced us to decline a number of very high quality submissions, which would be acceptable for publications in quality transportation journals. All in all, out of 230 extended abstract submissions, we have finally selected 35 papers to be included in this volume. We sincerely hope that this volume will serve as a vehicle to stimulate novel research initiatives in transportation and traffic theories.

As this volume was heading towards press, the news of Ryuichi Kitamura’s untimely death on 19 February 2009 struck us with sadness and a profound sense of loss. A professor at Kyoto University, Ryuichi had given his unstinting support to ISTTT as a Member of the IAC. All of us who had the good fortune of having met him were often touched by his cheerfulness, kindness, and generosity. His positive attitude and warmth endured even when he was suffering from a long illness. We shall sorely miss his scholarship and friendship.

This commemorative Symposium volume is dedicated to researchers, scientists, and practitioners who have spent their career advancing the state-of-the-art in
transportation and traffic theories. We celebrate their accomplishments and honor the memory of those who are not with us today.

Finally, we express our gratitude to the organizations whose financial contribution has made it possible for us to host the 18th ISTTT in Hong Kong.

William H. K. Lam, S.C. Wong and Hong K. Lo

March 2009
Remembering Ryuichi Kitamura

On February 19, 2009, many of us were saddened to hear of Ryuichi Kitamura’s passing. His close friends and colleagues had known for some time of his struggle with cancer, but had drawn hope from his appearances at conferences and occasional correspondence. He taught us a lot about how to be graceful in the face of adversity, as he remained his wonderful positive self until the end, and continued to write and conduct far-reaching research with his students and collaborators. He had hoped to attend the 18th ISTTT meeting in Hong Kong, but unfortunately it was not meant to be.

Ryuichi returned to Kyoto University, his alma mater, in 1993, as a Professor of Urban Management in the Faculty of Engineering, after a distinguished 15-year career on the faculty of the Department of Civil and Environmental Engineering at the University of California at Davis, where he was instrumental in founding the Institute for Transportation Studies (ITS). He received his BS in Civil Engineering and MS in Transportation in 1972 and 1974, respectively, from Kyoto University, and a PhD in Civil Engineering from the University of Michigan at Ann Arbor in 1978.

Through his research, teaching and professional service, Ryuichi played a key role in advancing the state of the art as well as state of practice in travel demand modeling and the dynamic analysis of transportation systems through micro-simulation of household travel and activity behaviour. He realized early on that travel demand does not occur for its own sake, but is part of a broader set of activities undertaken by individuals and households in fulfilling their various needs. He became a major force in the US and internationally in promoting greater behavioural realism in transportation models, leading the way towards comprehensive activity-based models of travel demand.

Ryuichi challenged conventional wisdom and brought a fresh perspective to nearly all topics on which he worked. He was a scholar, with a probing inquisitive mind, who subtly but firmly made you look at problems from a different angle. He was a keen observer of social trends, and among the first to recognize how they might impact travel and transportation. Telecommuting, changing gender roles, increased environmental awareness and shifting preferences are examples of phenomena he sought to understand and quantify in terms of transportation implications. Ryuichi was one of few researchers who had the methodological firepower to analyze these kinds of trends rigorously, ranging from novel survey methods to advanced econometric and psychometric techniques.

His quest for models based on sound behavioural theories was promoted through several disciples who studied under him at both Davis and Kyoto, and who went on to become influential scholars and practitioners in their own right. He helped
shape the field through his service as chair of the Traveller Behaviour and Values committee of the Transportation Research Board in the mid to late 1980’s, a time of major advances in both research and practice. He served as President of the International Association of Travel Behaviour Research (IATBR) in 1992-94, and hosted its triennial meeting in Kyoto in 2006. In that same year, the IATBR recognized his contributions by awarding him the Lifetime Achievement Award.

Ryuichi was a member of the International Advisory Committee of the ISTTT, and had discussed with us his desire to host it in Kyoto at some future date. It is unfortunate he did not live to see this wish fulfilled. We will miss his thoughtful interventions and good humour, the depth of insight and breadth of perspective he brought to the ISTTT, and his warm, pleasant and congenial personality. I will miss a dear friend, who contributed so much to making what we do the exciting privilege it truly is.

Supply-demand Diagrams and a New Framework for Analyzing the Inhomogeneous Lighthill-Whitham-Richards Model

W.L. Jin, University of California, U.S.A.; L. Chen, University of Science and Technology of China, China; Elbridge Gerry Puckett, University of California, U.S.A.

Abstract Traditionally, the Lighthill-Whitham-Richards (LWR) models for homogeneous and inhomogeneous roads have been analyzed in flux-density space with the fundamental diagram of the flux-density relation. In this paper, we present a new framework for analyzing the LWR model, especially the Riemann problem at a linear boundary in which the upstream and downstream links are homogeneous and initially carry uniform traffic. We first review the definitions of local supply and demand functions and then introduce the so-called supply-demand diagram, on which a traffic state can be represented by its supply and demand, rather than as density and flux as on a fundamental diagram. It is well-known that the solutions to the Riemann problem at each link are self-similar with a stationary state, and that the wave on the link is determined by the stationary state and the initial state. In our new framework, there can also exist an interior state next to the linear boundary on each link, which takes infinitesimal space, and admissible conditions for the upstream and downstream stationary and interior states can be derived in supply-demand space. With an entropy condition consistent with a local supply-demand method in interior states, we show that the stationary states exist and are unique within the solution framework. We also develop a graphical scheme for solving the Riemann problem, and the results are shown to be consistent with those in the literature. We further discuss asymptotic stationary states on an inhomogeneous ring road with arbitrary initial conditions and demonstrate the existence of interior states with a numerical example. The framework developed in this study is simpler than existing ones and can be extended for analyzing the traffic dynamics in general road networks.
1. Introduction

Essential to effective and efficient transportation control, management, and planning strategies is a better understanding of the evolution of traffic dynamics on a road network; i.e., the formation, propagation, and dissipation of traffic queues. The seminal work by (Lighthill and Whitham 1955) and (Richards 1956) (LWR) attempts to study traffic dynamics with respect to aggregate values such as density $\rho$, speed $v$, and flux $q$. Based on a continuous version of traffic conservation

$$\frac{\partial \rho}{\partial t} + \frac{\partial q}{\partial x} = 0,$$

and an assumption about the fundamental diagram of the flux-density relation $q = Q(\rho)$, the LWR model of a homogeneous road link can be written as

$$\frac{\partial \rho}{\partial t} + \frac{\partial Q(\rho)}{\partial x} = 0.$$  

The corresponding speed-density relation is $v = V(\rho) = Q(\rho)/\rho$. Here the maximum or jam density is denoted by $\rho_j$; i.e., $\rho \in [0, \rho_j]$. Usually, $V(\rho)$ is a non-increasing function of traffic density, $v_f = V(0)$ is the free flow speed, $V(\rho_j) = 0$, and $q = Q(\rho)$ is unimodal with maximum flux or capacity $C = Q(\rho_c)$ where $\rho_c$ is the critical density. Finally, traffic states with density higher than $\rho_c$ are congested or over-critical, and those with density lower than $\rho_c$ are free flowing or under-critical.

Compared with microscopic traffic flow models (e.g. Gazis et al. 1961; Nagel and Schreckenberg 1992) the LWR model can be used to analyze traffic evolution at the aggregate level with shock and rarefaction waves. With its analytical power and simplicity, the LWR theory has been extended for studying traffic dynamics in more general transportation networks. For examples, Daganzo (1997) proposed a traffic flow model for freeways with special lanes and high-occupancy vehicles with a two-regime fundamental diagram, and Wong and Wong (2002) proposed a multi-class model for heterogeneous drivers.

In this paper, we are interested in the LWR model for a road with bottlenecks, where traffic characteristics such as free flow speed, jam density, the number of lanes, and capacity may be different for different locations. In other words, the fundamental diagram $q = Q(x, \rho)$ depends on location. Such a road link is called inhomogeneous and the corresponding inhomogeneous LWR model can be written as

$$\frac{\partial \rho}{\partial t} + \frac{\partial Q(x, \rho)}{\partial x} = 0.$$  

In order to understand the fundamental properties of equation (3), we usually analyze its Riemann problem at $x = 0$. Hereafter, we will refer to the upstream branch as link 1, the downstream branch as link 2, and $x = 0$ as a linear boun-
boundary. In the Riemann problem, links 1 and 2 are both homogeneous and initially carry uniform traffic. That is,

\[
Q(x, \rho) = \begin{cases} 
Q_1(\rho), & x < 0, \\
Q_2(\rho), & x > 0,
\end{cases}
\]

and

\[
\rho(x, t = 0) = \begin{cases} 
\rho_1, & x < 0, \\
\rho_2, & x > 0.
\end{cases}
\]

Since (Mochon 1987), there have been many analytical and numerical studies related to the inhomogeneous LWR model in the literature. Roughly speaking, there have been two types of methods for solving the Riemann problem of inhomogeneous LWR model 1. In the first type, the inhomogeneous LWR model can be analyzed as a non-strictly hyperbolic conservation law (Isaacson and Temple 1992; Lin et al. 1995; Jin and Zhang 2003a) or as a hyperbolic conservation law with a discontinuous flux function (Gimse and Risebro 1990; Gimse 1993; Kliingenberg and Risebro 1995; Diehl 1995, 1996b; Diehl and Wallin 1996; Diehl 1996a; Zhang and Liu 2003; Burger et al. 2005, 2008), and various numerical methods can be used (Bale et al. 2002; Zhang and Liu 2005a,b; Zhang et al. 2006; Herty et al. 2007). In the second type, the self-similar waves of the Riemann solutions are separated into links 1 and 2 by introducing a stationary state for each link, and the wave on each link is determined by a new Riemann problem of the corresponding homogeneous LWR model (Seguin and Vovelle 2003; Garavello et al. 2007). Here the stationary states are subject to admissible conditions as well as certain entropy conditions. This solution framework was first proposed for solving Riemann problems at general junctions with more than one upstream and downstream link (Holden and Risebro 1995; Coclite et al. 2005). In (Seguin and Vovelle 2003), the method was introduced for solving the inhomogeneous LWR model, and the stationary states are solved for a specific example. In (Garavello et al. 2007), a more general approach was proposed for solving the stationary states with a singular map method. However, all these existing methods solve the Riemann problem in flux-density space: the first type of method is tedious due to the need to analyze kinematic waves on both links at the same time, and the second type of method fails to present the entropy condition in a physically meaningful way. In addition, all existing methods do not account for interior states in stationary shock waves (van Leer 1984; Bultelle et al. 1998) and cannot be easily extended for studying traffic dynamics in a road network (Jin 2003). Note that, in this paper, we do not intend to study numerical solution methods for solving the inhomogeneous LWR model.

\[\text{In (Daganzo 2006), the inhomogeneous LWR model is solved in the space of cumulative number of vehicles as a calculus of variations problem, and the existence of its solution is proved for road links with point bottlenecks. However, the wave solutions of the Riemann problem are not explicitly discussed.}\]
In this paper, we present a new framework for analyzing the inhomogeneous LWR model. We also adopt the method of wave separation by (Holden and Risebro 1995), but introduce a stationary state and an interior state for each branch. Here stationary states are the self-similar states at the boundary, and interior states do not take any space in the continuous solution and only show up in the numerical solutions as observed in (van Leer 1984; Bultelle et al. 1998). Rather than using the fundamental diagram, we introduce a so-called supply-demand diagram and discuss the problem in supply-demand space. After deriving admissible solutions for upstream and downstream stationary and interior states in supply-demand space, we introduce an entropy condition based on the discrete supply-demand method (Daganzo 1995a; Lebacque 1996). We then prove that stationary states exist and are unique for given upstream demand and downstream supply, and interior states exist but may not be unique. Further we compare the Riemann solutions obtained by the new method with those in the literature for both the homogeneous and inhomogeneous LWR models. We also apply the new framework for analyzing asymptotic stationary states on an inhomogeneous ring road and demonstrate the existence of interior states with numerical examples.

The rest of the paper is organized as follows. In Section 2, we review the definitions of the supply and demand functions and the discrete supply-demand method for computing boundary fluxes. In Section 3, we introduce the supply-demand diagrams and the structure of the solutions to the Riemann problem of the inhomogeneous LWR model in supply-demand space. In Section 4, we derive the admissible conditions for stationary and interior states in supply-demand space and an entropy condition consistent with the local supply-demand method in interior states. In Section 5, we solve the Riemann problem for both the homogeneous and inhomogeneous LWR models and present a graphical solution scheme. In Section 6, we analyze asymptotic stationary states on an inhomogeneous ring road and demonstrate the existence of interior states with numerical solutions. In Section 7, we conclude our study with a discussion of future directions.

2. Review of the Supply-demand Functions and Methods

2.1 Review of Engquist-Osher Functions and the Godunov Method for Convex Conservation Laws

For the original LWR model (2), assuming that $k = \rho_c - \rho$, we obtain a hyperbolic conservation law in $k \in [-\rho_c, \rho_j - \rho_c]$ as follows

$$\frac{\partial k}{\partial t} + \frac{\partial f(k)}{\partial x} = 0,$$

(6)
A New Framework for Analyzing the Inhomogeneous Lighthill-Whitham-Richards Model

where \( f(k) = C - Q(\rho_c - k) \) is convex when \( Q(\rho) \) is concave, since
\[
\frac{\partial^2 f(k)}{\partial k^2} = -\frac{\partial^2 Q(\rho)}{\partial \rho^2} \geq 0.
\] Here \( f(0) = 0 \). Moreover, if \( q = Q(\rho) \) is the Greenshields fundamental diagram (Greenshields 1935), then (6) is Burgers’ equation.

For the nonlinear equation (6), we usually have to resort to numerical solutions for general initial and boundary conditions. After dividing the time duration into a number of time intervals of \( \Delta t \) and splitting the road link into a number of cells of width \( \Delta x \), the finite difference equation in conservation form can be written as follows (Colella and Puckett 2004; LeVeque 2002):
\[
k_i^{j+1} = k_i^j - \frac{\Delta t}{\Delta x} \left( f_{i+1/2}^{j*} - f_{i-1/2}^{j*} \right),
\]
where \( k_i^j \) is the average value of \( k(x_i,t) \) in cell \( i \) between \( x_i - \frac{\Delta x}{2} \) and \( x_i + \frac{\Delta x}{2} \) at time step \( j \), and \( f_{i+1/2}^{j*} \) is the flux through the boundary \( x_i + \frac{\Delta x}{2} \) between time steps \( j \) and \( j+1 \). Here \( \Delta x \) and \( \Delta t \) have to satisfy the so-called CFL condition (Courant et al. 1928).

For a hyperbolic conservation law (6), the following functions were first introduced by (Engquist and Osher 1980a,b, 1981; Osher and Solomon 1982)
\[
g(k) = f(\max\{\rho,0\}) = \begin{cases} f(k), & \text{if } k \geq 0 \\ 0, & \text{if } k \leq 0 \end{cases},
\]
\[
h(k) = f(\min\{\rho,0\}) = \begin{cases} f(k), & \text{if } k \leq 0 \\ 0, & \text{if } k \geq 0 \end{cases},
\]
where \( \chi(k) \) equals 1 ifff \( f'(k) \geq 0 \) and equals 0 otherwise. Note that \( f(k) = g(k) + h(k) \) and \( f(k) = \max\{g(k),h(k)\} \). Therefore, we can rewrite equation (6) in the following form:
\[
k_i^j + g(k_i^j) + h(k_i^j) = 0,
\]
\[
k_i^j + \left[ \max\{g(k),h(k)\} \right]_{x_i} = 0.
\]
Further, based on these definitions, the following E-O flux is introduced (Engquist and Osher 1980b; Osher 1984)
\[
f_{i-1/2}^{j*} = g(k_{i-1}^j) + h(k_i^j) = f(k_{i-1}^j) + \int_{k_{i-1}}^{k_i} \min\{f'(s),0\} ds
\]
\[
= f(k_i^j) - \int_{k_{i-1}}^{k_i} \max\{f'(s),0\} ds
\]
\[
= \frac{1}{2} \left[ f(k_{i-1}^j) + f(k_i^j) - \int_{k_{i-1}}^{k_i} |f'(s)| ds \right].
\]
That is, (7) can be written as
\[ k_i^{j+1} = k_i^j - \frac{\Delta t}{\Delta x} \left( h(k_i^{j+1}) - h(k_i^{j}) + g(k_i^{j}) - g(k_i^{j-1}) \right). \] (13)

This can be considered as an upwind method for equation (10), since \( g(k) \) is non-decreasing and \( h(k) \) non-increasing.

In (van Leer 1984), the Godunov flux (Godunov 1959) for Burgers’ equation was written as
\[ f_{i-1/2}^* = \max \{ g(k_i^{j}), h(k_i^{j}) \}. \] (14)

In (Osher 1984), a new formulation of the Godunov flux was introduced as
\[ f_{i-1/2}^* = \max \{ g(k_i^{j}), h(k_i^{j}) \}. \] (15)

For convex \( f(k) = \max \{ g(k), h(k) \} \), since \( g(k) \) and \( h(k) \) are monotonically increasing and decreasing respectively, this is equivalent to
\[ f_{i+1/2}^* = \begin{cases} 
\max \{ \min \{ g(k), \min h(k) \}, \quad k_{i+1} \leq k_i^j \} \\
\max \{ \max g(k), \max h(k) \}, \quad k_i^j > k_{i+1} 
\end{cases} \]
\[ = \max \{ g(k_{i+1}), h(k_i^{j}) \}. \]

That is, equation (15) is equivalent to equation (14). However, it has been shown that equation (15) can also be applied to non-convex \( f(k) \).

### 2.2 Review of Supply and Demand Functions and Godunov Methods for the LWR Model

For the LWR model (2), we define the following functions
\[ D(\rho) = Q(\min \{ \rho, \rho_c \}) = \begin{cases} 
Q(\rho), & \text{if } \rho \leq \rho_c \\
C, & \text{if } \rho \geq \rho_c 
\end{cases}, \] (16)
\[ S(\rho) = Q(\max \{ \rho, \rho_c \}) = \begin{cases} 
Q(\rho), & \text{if } \rho \geq \rho_c \\
C, & \text{if } \rho \leq \rho_c 
\end{cases}, \] (17)
\[ \int_0^\rho \chi(s)Q'(s)ds = \int_0^\rho \max \{ Q'(s), 0 \} ds \]
\[ = C + \rho \sqrt{1 - \chi(s)Q'(s)} ds = C + \rho \max \{ Q'(s), 0 \} ds, \]
where \( \chi(\rho) \) equals 1 iff \( Q'(\rho) \geq 0 \) and equals 0 otherwise. It is straightforward to show that \( D(\rho) = C - g(k) \) and \( S(\rho) = C - h(k) \). Therefore, the Godunov method for (2) is equivalent to
\[ \rho_i^{j+1} = \rho_i^j - \frac{\Delta t}{\Delta x} \left( q_{i+1/2}^* - q_{i-1/2}^* \right), \] (18)
where the boundary flux can be written as (van Leer 1984)
A New Framework for Analyzing the Inhomogeneous Lighthill-Whitham-Richards Model

\[ q_{i-1/2}^* = \min \{ D(\rho_{i-1}^j), S(\rho_j^i) \}, \quad (19) \]

or as (Osher 1984)

\[ q_{i-1/2}^* = \begin{cases} \min_{\rho_{i-1}^j \leq \rho_j < \rho_i^j} Q(\rho), & \rho_i^j < \rho_i \leq \rho_j \\ \max_{\rho_i \leq \rho_j < \rho_{i-1}^j} Q(\rho), & \rho_i \leq \rho_i^j \leq \rho_j \end{cases}, \quad (20) \]

From (20), we can see that (19) is valid as long as the fundamental diagram \( Q(\rho) \) is unimodal and may not be concave.

In the transportation literature, (Bui et al. 1992) first applied (18) and (20) for solving the LWR model. In (Daganzo 1995a), a new finite difference form was proposed for the LWR model with a triangular or trapezoidal fundamental diagram

\[ Q(\rho) = \min \{ v_f \rho, v_c (\rho_j - \rho), Q_{\text{max}} \} \quad (21) \]

where \( v_c = v_f \frac{\rho_j - \rho_i}{\rho_i - \rho_j} \) is the absolute value of the shock wave speed in congested traffic. In the so-called cell transmission model (CTM), the space-time domain was discretized with a CFL number of 1; i.e., \( \Delta x = v_f \Delta t \), and the boundary flux in (18) was written as

\[ q_{i-1/2}^* = \min \{ \bar{D}(\rho_{i-1}^j), \bar{S}(\rho_j^i) \}, \quad (22) \]

where \( \bar{D}(\rho_j^i) \Delta t = \min \{ Q_{\text{max}} \Delta t, n_j^i \} \) and \( \bar{S}(\rho_j^i) \Delta t = \min \{ Q_{\text{max}} \Delta t, \frac{N_{\text{max}} - n_j}{v_f} \} \) are defined as “the maximum flows that can be sent and received by cell \( i \) in the interval between time steps \( j \) and \( j+1 \)”, \( n_j^i = \rho_j^i \Delta x = \rho_j v_f \Delta t \) is the number of vehicles in cell \( i \) at time step \( j \), and \( N_{\text{max}} = \rho_j \Delta x = \rho_i v_f \Delta t \) is the maximum number of vehicles in cell \( i \). Hence the physical meaning of (22) is that the boundary flux is the minimum of the upstream sending flux and the downstream receiving flux. It can be shown that \( \bar{D}(\rho) = D(\rho) \) and \( \bar{S}(\rho) = S(\rho) \). Thus, (22) is equivalent to (19) for a CFL number of 1 and triangular or trapezoidal fundamental diagrams.

Following (Lebacque 1996), we refer to \( D(\rho) \) in (16) and \( S(\rho) \) in (17) as the demand and supply functions respectively and call (19) the discrete supply-demand method for computing fluxes. The physical interpretations of demand and supply functions and the supply-demand method have formed the basis for extending the supply-demand method for computing fluxes through various network junctions (Daganzo 1995a; Lebacque 1996; Jin 2003). For inhomogeneous roads, the extension is straightforward as follows (Daganzo 1995a; Lebacque 1996): the demand and supply functions in (16) and (17) are location-dependent, \( D(x, \rho(x, t)) = Q(x, \min \{ \rho(x, t), \rho_j(x) \}) \) and \( S(x, \rho(x, t)) = Q(x, \max \{ \rho(x, t), \rho_j(x) \}) \), and the flux is still computed by the supply-demand method (19), \( q_{i-1/2}^* = \min \{ D_{i-1}(\rho_{i-1}^j), S_j(\rho_j^i) \} \), where \( D_{i-1}(\rho) \) is the demand function in cell \( i-1 \), and \( S_j(\rho) \) is the supply function in cell \( j \). It has been shown that the flux by
the extended supply-demand method is still the Godunov flux (Jin and Zhang 2003a; Zhang and Liu 2003).

In this study, based on the Godunov finite difference equation in (18) and the supply-demand method in (19) for computing boundary fluxes, we attempt to construct the convergent solution of (3) with discontinuous flux functions (4) and initial conditions (5). In (Daganzo 1995b), the convergence, truncation error, and capture of shock waves were directly derived from the corresponding finite difference equation of the homogeneous LWR model. Here, we attempt to present a new framework and find the solutions to the Riemann problem of the inhomogeneous LWR model at a linear boundary.

3. Supply-demand Diagrams and the Structure of Riemann Solutions

In the literature, the inhomogeneous LWR model has been analyzed in flux-density space. Since a traffic state in flux-density space \((\rho, q)\) can also be represented in supply-demand space as \(U = (D, S)\), in this study we will analyze the inhomogeneous LWR model in supply-demand space. Furthermore, we present the structure of solutions to the Riemann problem of the inhomogeneous LWR model in supply-demand space.

3.1 Supply-demand Diagrams

Corresponding to the fundamental diagram in flux-density space, a supply-demand diagram can be introduced in supply-demand space. In Fig. 1(b), we draw a supply-demand diagram for the two fundamental diagrams in Fig. 1(a). On the dashed branch of the supply-demand diagram, traffic is under-critical (UC) and \(U = (D, C)\) with \(D \leq C\); on the solid branch, traffic is over-critical (OC) and \(U = (C, S)\) with \(S \leq C\). Compared with the fundamental diagram of a road section, the supply-demand diagram only considers capacity \(C\) and congestion level of traffic flow, but not other detailed characteristics such as critical density, jam density, or relationship between density and flux. That is, different fundamental diagrams can have the same supply-demand diagram, as long as they have the same capacity and are unimodal, and their critical densities, jam densities, or shapes are not relevant. However, there is always a one-to-one mapping between a given supply-demand diagram and its corresponding fundamental diagram. That is, there exists a one-to-one mapping between \((\rho, q)\) and \((D, S)\).
For the demand and supply functions in (16) and (17), we can see that $D$ is non-decreasing with $\rho$ and $S$ non-increasing. Thus $D \leq C$, and $S \leq C$, and $\max\{D,S\} = C$. In addition, $D = S = C$ iff traffic is critical; $D < S = C$ iff traffic is strictly under-critical (SUC); $S < D = C$ iff traffic is strictly over-critical (SOC). Therefore, the state $U = (D, S)$ is under-critical (UC), iff $S = C$, or equivalently $D \leq S$. The state $U = (D, S)$ is over-critical (OC), iff $D = C$, or equivalently $S \leq D$.

From a state on the supply-demand diagram, we can obtain the corresponding flux $q(U) = \min\{D,S\}$ and capacity $C = \max\{D,S\}$. However, we cannot tell the density from the supply-demand diagram, and the fundamental diagram is still needed to compute the density $\rho$ from $(D,S)$. That is, $\rho$ can be written as a function of $(D,S)$ as

$$\rho(D,S) = \begin{cases} D^{-1}(D), & D \leq S, \\ S^{-1}(S), & S < D, \end{cases}$$

since $D(\rho)$ and $S(\rho)$ are invertible when the traffic is UC and OC respectively. Note that $\rho$ is not a function of $q$. If we introduce the supply-demand ratio $\gamma = D/S$, then $q(D,S) = \min\{1,1/\gamma\} \cdot C$, and

$$\rho(D,S) = R(\gamma) \equiv \begin{cases} D^{-1}(\gamma C), & \gamma \leq 1, \\ S^{-1}(\gamma C), & \gamma > 1, \end{cases}$$

where $R(\gamma)$ is an increasing function in $\gamma \in [0,\infty]$. Here $R(0) = 0$, $R(1) = \rho_c$, and $R(\infty) = \rho_f$. In this sense, $\rho = R(\gamma)$ can be considered as the inverse flux-density relationship. Similarly, $v = V(\rho) = V(R(\gamma))$ is a non-increasing function in $\gamma$, $V(0) = v_f$, and $V(\infty) = 0$. 

**Fig. 1.** The fundamental diagram and its supply-demand diagram
3.2 The Structure of Solutions to the Riemann Problem

In supply-demand space, initial conditions (5) are equivalent to

\[
U(x, t = 0) = \begin{cases} 
U_1 = (D_1, S_1), & x < 0, \\
U_2 = (D_2, S_2), & x > 0.
\end{cases}
\] (23)

The Riemann problem at a linear boundary is then equivalent to the Riemann problem for (3) with initial conditions (23).

Unlike existing studies of hyperbolic conservation laws with discontinuous flux functions, in which solutions to the Riemann problem have been constructed in $\rho - q$ space, within the framework of wave separation developed in (Holden and Risebro 1995), we construct the solutions to the Riemann problem for (3) with initial conditions (23) in supply-demand space.

In solutions to the Riemann problem for (3) with initial conditions (23), a shock wave or a rarefaction wave could initiate on a link from the linear boundary $x = 0$, and traffic states on both links become asymptotically stationary after a long time. We denote the stationary state on the upstream link 1 by $U_1^-$ and the stationary state on the downstream link 2 by $U_2^+$. At the boundary, there can also exist interior states (van Leer 1984; Bultelle et al. 1998), which take infinitesimal space. We denote the interior states on links 1 and 2 by $U_1(0^-, t)$ and $U_2(0^+, t)$ respectively. The structure of Riemann solutions on upstream and downstream links are shown in Fig. 2.

\[ \text{Fig. 2. Structure of Riemann solutions: (a) Upstream link 1; (b) Downstream link 2} \]

Then the kinematic wave on the upstream link 1 is the solution of the corresponding homogeneous LWR model with initial left and right conditions of $U_1$ and $U_1^-$, respectively. Similarly, the kinematic wave on the downstream link 2 is the solution of the corresponding LWR model with initial left and right conditions of $U_2^+$ and $U_2$, respectively. Since the stationary and interior states are constant for $t > 0$, states on both links 1 and 2 are self-similar (Smoller 1983). That is, if stationary states exist and are unique, we have unique self-similar solutions for the Riemann problem of (3). In the following sections, we first derive necessary conditions for both stationary and interior states and then solve them in supply-demand space.
4. Necessary Conditions for the Existence of Stationary and Interior States

We denote $q_{1\rightarrow 2}(0,t)$ as the flux from link 1 to link 2. We first observe that the fluxes are determined by the stationary states: the asymptotic out-flux of link 1 is $q_1(0^-,t) = q(U_1^-)$, and the asymptotic in-flux of link 2 is $q_2(0^+,t) = q(U_2^+)$. Furthermore, from the conservation of traffic at the linear boundary, we have

$$q_{1\rightarrow 2}(0,t) = q_1(0^-,t) = q_2(0^+,t) = q(U_1^-) = q(U_2^+).$$  \hspace{1cm} (24)

4.1. The Admissible Conditions for Stationary States

As observed in (Holden and Risebro 1995; Coclite et al. 2005), the speed of the kinematic wave on an upstream link cannot be positive, and that on a downstream link cannot be negative. We have the following theorem.

Fig. 3. Admissible stationary states for upstream link 1
Theorem 1 (Admissible stationary states). For initial conditions in (23), stationary states are admissible if and only if
\[ U_1^- = (D_1, C_1) \text{ or } (C_1, S_1^-), \]
where \( S_1^- < D_1 \), and
\[ U_2^+ = (C_2, S_2) \text{ or } (D_2^+, C_2), \]
where \( D_2^+ < S_2 \). The results are illustrated in Figs. 3 and 4.

Proof When the initial state on link 1 is strictly under-critical; i.e., when \( D_1 < S_1 = C_1 \), the admissible stationary state \( U_1^- \) is the same as \( U_1 = (D_1, C_1) \) or strictly over-critical with \( U_1^- = (C_1, S_1^-) \), where \( S_1^- < D_1 \). In this case, the Riemann problem for the LWR model on the upstream link 1 with upstream and downstream initial states \( U_1 = (D_1, C_1) \) and \( U_1^- \) has the following possible solutions: there is no wave when \( U_1^- = U_1 \); there is a backward traveling shock wave when \( U_1^- = (C_1, S_1^-) \). In addition, we can verify that any stationary states not equal to \( U_1 \) and with \( S_1^- > D_1 \) will lead to forward traveling shock waves or rarefaction waves. Note that when \( U_1^- = (C_1, D_1) \), the Riemann problem is
solved by a zero shock wave, but $U_1^-$ cannot be the stationary state by definition. When the initial state on link 1 is over-critical; i.e., when $S_1 \leq D_1 = C_1$, the admissible stationary state $U_1^-$ is over-critical with $U_1^- = (C_1, S_1^-)$, where $S_1^- \leq C_1$. In this case, the Riemann problem for the LWR model on the upstream link 1 with upstream and downstream initial states $U_1 = (C_1, S_1)$ and $U_1^- = (C_1, S_1^-)$ has the following possible solutions: there is no wave when $S_1^- = S_1$; there is a backward traveling shock wave when $S_1 > S_1^-$; and there is a backward traveling rarefaction wave when $S_1 < S_1^-$. Therefore, the stationary state is indeed admissible. In addition, we can verify that any strictly under-critical stationary states $U_1^-$ will lead to forward traveling rarefaction waves and are not admissible.

When the initial state on link 2 is under-critical; i.e., when $D_2 \leq S_2 = C_2$, the admissible stationary state $U_2^+$ is under-critical with $U_2^+ = (D_2^+, C_2)$, where $D_2^+ \leq C_2$. In this case, the Riemann problem for the LWR model on the downstream link 2 with upstream and downstream initial states $U_2^+ = (D_2^+, C_2)$ and $U_2 = (D_2, C_2)$ has the following possible solutions: there is no wave when $D_2^+ = D_2$; there is a forward traveling shock wave when $D_2^+ < D_2$; there is a forward traveling rarefaction wave when $D_2^+ > D_2$. Therefore, the stationary state is indeed admissible. In addition, we can verify that any strictly over-critical stationary states $U_2^+$ will lead to backward traveling rarefaction waves and are not admissible. When the initial state on link 2 is strictly over-critical; i.e., when $S_2 < D_2 = C_2$, the admissible stationary state $U_2^+$ is the same as $U_2 = (C_2, S_2)$ or strictly under-critical with $U_2^+ = (D_2^+, C_2)$, where $D_2^+ < S_2$. In this case, the Riemann problem for the LWR model on the downstream link 2 with upstream and downstream initial states $U_2^+$ and $U_2 = (D_2, C_2)$ has the following possible solutions: there is no wave when $U_2^+ = U_2$; there is a forward traveling shock wave when $U_2^+ = (D_2^+, C_2)$. In addition, we can verify that any stationary states not equal to $U_2$ and with $D_2^+ > S_2$ will lead to backward traveling shock waves or rarefaction waves. Note that when $U_2^+ = (S_2, C_2)$, the Rie-
mann problem is solved by a zero shock wave, but $U_2^+$ cannot be the stationary state by definition.

**Remark 1** Note that $U_1^- = U_1$ and $U_2^+ = U_2$ are always admissible. In this case, the stationary states are the same as the corresponding initial states, and there are no waves.

**Remark 2** From the proof of theorem 1, we can see that the types and traveling directions of waves on a homogeneous road can be solely determined by upstream demand and downstream supply and are not related to the shape of fundamental diagrams. This is why we are able to discuss the Riemann problem of the inhomogeneous LWR model in supply-demand space. Note that, however, the wave speeds are related to the details of the flux-density relation $Q(\rho)$.

**Remark 3** Then the out-flux $q_1(0^-,t) = q(U_1^-) = \min\{D_1^-, S_1^-\} \leq D_1$ and the in-flux $q_2(0^+,t) = q(U_2^+) = \min\{D_2^+, S_2^+\} \leq S_2$. That is, $D_1$ is the maximum sending flux and $S_2$ is the maximum receiving flux in the sense of (Daganzo 1994, 1995a). Furthermore, $q_1(0^-,t) = D_1$, iff $U_1^- = (D_1, C_1)$, and iff $U_1^-$ is UC; $q_1(0^-,t) < D_1$ iff $U_1^- = (C_1, S_1^-)$ with $S_1^- < D_1$, and iff $U_1^-$ is SOC. Similarly, $q_2(0^+,t) = S_2$, iff $U_2^+ = (C_2, S_2)$, and iff $U_2^+$ is OC; $q_2(0^+,t) < S_2$ iff $U_2^+ = (D_2^+, C_2)$ with $D_2^+ < S_2$, and iff $U_2^+$ is SUC.

### 4.2 The Admissible Conditions for Interior States

The Riemann problem on link 1 with left and right initial conditions of $U_1^-$ and $U_1(0^-,t)$ cannot have negative waves. Otherwise, $U_1(0^-,t)$ will propagate upstream and violates the condition that it only exists at the boundary, but not anywhere upstream. Similarly, the Riemann problem on link 2 with left and right initial conditions of $U_2(0^+,t)$ and $U_2^+$ cannot have positive waves. Therefore, interior states $U_1(0^-,t)$ and $U_2(0^+,t)$ should satisfy the following admissible conditions.
Fig. 5. Admissible interior states for upstream link 1

Fig. 6. Admissible interior states for downstream link 2
Theorem 2 (Admissible interior states). For asymptotic stationary states $U_1^-$ and $U_2^+$, interior states $U_1(0^-,t)$ and $U_2(0^+,t)$ are admissible if and only if
\[
U_1(0^-,t) = \begin{cases} 
(C_1, S_1^-) = U_1^-,& \text{when } S_1^- < D_1^- = C_1 \\
(D_1(0^-,t), S_1(0^-,t)),& \text{when } D_1^- \leq S_1^- = C_1
\end{cases}
\] (27)
where $S_1(0^-,t) \geq D_1^-$. The results are illustrated in Figs. 5 and 6.

Proof The results can be verified with the observation that the Riemann solutions for the homogeneous LWR model of the upstream links cannot have negative waves and those of the downstream links cannot have positive waves.

Remark 1 Note that $U_1(0^-,t) = U_1^-$ and $U_2(0^+,t) = U_2^+$ are always admissible. In this case, the interior states are the same as stationary states, and it is equivalent to saying that there are no interior states.

4.3 An Entropy Condition for the Local Supply-demand Method

In addition to traffic conservation and admissible conditions, we introduce an entropy condition such that the boundary flux is always consistent with that by the supply-demand method (19) for the local interior states. At the boundary at $x = 0$, the immediate upstream state is $U_1(0^-,t)$, and the immediate downstream state $U_2(0^+,t)$. That is, the interior states have to satisfy the following entropy condition
\[
q_{1 \rightarrow 2}(0,t) = \min \{D_1(0^-,t), S_2(0^+,t)\}.
\] (29)
Note that the entropy condition (29) is also equivalent to the following localized optimization problem
\[
\max \{q_{1 \rightarrow 2}(0,t) = q_1(0^-,t) = q_2(0^+,t)\}
\]
such that
\[
q_1(0^-,t) \leq D_1(0^-,t),
\]
\[
q_2(0^+,t) \leq S_2(0^+,t).
\]
That is, the stationary and interior states are solutions of the optimization problem in the domain defined by the traffic conservation condition (24), the admissible conditions for stationary states (25-26), and the admissible conditions for interior
states (27-28). Optimization formulations of entropy conditions were also adopted in (Holden and Risebro 1995; Coclite et al. 2005), but in terms of stationary states in flux-density space rather than in supply-demand space as we have done here.

In all of the necessary conditions above, we can see that the stationary and interior states are independent of the upstream supply, \( S_1 \), and the downstream demand, \( D_2 \). That is, the same upstream demand and downstream supply will yield the same solutions of stationary and interior states: when the upstream traffic is congested, its congestion level is not relevant to the stationary and interior states or the boundary flux; when the downstream traffic is free flow, its density is not relevant to the stationary and interior states or the boundary flux. Note that, however, the types and speeds of waves on both links can be related to \( S_1 \) as shown in Fig. 3(d) and \( D_2 \) as shown in Fig. 4(d).

5. Solutions to the Riemann Problem for the Inhomogeneous LWR Model

For the Riemann problem of (3) with initial conditions (23), we first solve for the stationary and interior states that satisfy the traffic conservation condition (24), the admissible conditions for stationary states (25-26), the admissible conditions for interior states (27-28), and the entropy condition (29). Then we compare them with existing solutions for both the homogeneous and inhomogeneous LWR models.

**Lemma 1** In the Riemann solutions, the boundary flux satisfies

\[
q_{1\rightarrow 2}(0,t) = q(U_1^-) = q(U_2^+) = \min\{D_1, S_2\}. \tag{30}
\]

**Proof** From theorem 1 and traffic conservation (24), we have that

\[
q_{1\rightarrow 2}(0,t) = q(U_1^-) = q(U_2^+) \leq \min\{D_1, S_2\}. \tag{31}
\]

We demonstrate that it is not possible for \( q_{1\rightarrow 2}(0,t) < \min\{D_1, S_2\} \). Otherwise, we assume that \( q_{1\rightarrow 2}(0,t) = q_0 < \min\{D_1, S_2\} \). Since \( q(U_1^-) = q_0 < D_1 \), from (25) we have that \( U_1^- = (C_1, q_0) \). Further from (27) we have that \( U_1(0^+,t) = U_1^- = (C_1, q_0) \). Hence \( D_1(0^+,t) = C_1 \). Similarly, since \( q(U_2^+) = q_0 < S_2 \), from (26) we have that \( U_2^+ = (q_0, C_2) \). Further from (28) we have that \( U_2(0^+,t) = U_2^+ = (q_0, C_2) \). Hence \( S_2(0^+,t) = C_2 \). Then from (29) we have \( q_{1\rightarrow 2}(0,t) = \min\{C_1, C_2\} \), which contradicts the assumption that \( q_{1\rightarrow 2}(0,t) < \min\{C_1, C_2\} \). Therefore we have (30).
That is, the local optimal solution in (29) leads to a global optimal flux at a linear boundary, which satisfies the following optimization problem

\[
\max \{ q_{1\rightarrow 2}(0,t) \}
\]

subject to

\[
q_{1\rightarrow 2}(0,t) \leq D_1, \quad q_{1\rightarrow 2}(0,t) \leq S_2.
\]

Therefore, in the Godunov finite difference equation (18), the boundary flux at the first time step by (19) is the same as the asymptotic flux, regardless of the time step size. That is, the discrete flux in (19) is consistent with the continuous flux in (29).

**Theorem 3** The stationary states and interior states of the Riemann problem for (3) with initial conditions (23) are the following:

1. When \( D_1 < S_2 \), we have unique stationary and interior states:

\[
U_1^- = U_1(0^-,t) = (D_1,C_1) \quad \text{and} \quad U_2^+ = U_2(0^+,t) = (D_1,C_2);
\]

2. When \( D_1 > S_2 \), we have unique stationary and interior states:

\[
U_1^- = U_1(0^-,t) = (C_1,S_2) \quad \text{and} \quad U_2^+ = U_2(0^+,t) = (C_2,S_2);
\]

3. When \( D_1 = S_2 \), we have unique stationary states: \( U_1^- = (D_1,C_1) \), and \( U_2^+ = (C_2,S_2) \); but interior states may not be unique: \( U_1(0^-,t) = (D_1,C_1) \) and \( D_2(0^+,t) \geq S_2 \) and \( S_2(0^+,t) \geq S_2 \), or \( U_2(0^+,t) = (C_2,S_2) \) and \( S_1(0^-,t) \geq D_1 \) and \( D_1(0^-,t) \geq D_1 \).

**Proof** When \( D_1 < S_2 \leq C_2 \), (30) leads to \( q_{1\rightarrow 2}(0,t) = D_1 \). For link 1, since \( q(U_1^-) = D_1 \), from (25) we have that \( U_1^- = (D_1,C_1) \). Further from (27) we have that \( U_1(0^-,t) = (D_1(0^-,t),S_1(0^-,t)) \) with \( S_1(0^-,t) \geq D_1^- = D_1 \). For link 2, since \( q(U_2^+) = D_1 < S_2 \), from (26) we have that \( U_2^+ = (D_1,C_2) \). Further from (28) we have that \( U_2(0^+,t) = U_2^+ = (D_1,C_2) \). Then from (29) we have \( q_{1\rightarrow 2}(0,t) = \min \{ D_1(0^-,t),C_2 \} = D_1 \). Therefore, \( D_1(0^-,t) = D_1 \) and \( S_1(0^-,t) = C_1 \).

When \( S_2 < D_1 \leq C_1 \), (30) leads to \( q_{1\rightarrow 2}(0,t) = S_2 \). For link 1, since \( q(U_1^-) = S_2 < D_1 \), from (25) we have that \( U_1^- = (C_1,S_2) \). Further from (27) we have that \( U_1(0^-,t) = U_1^- = (C_1,S_2) \). For link 2, since \( q(U_2^+) = S_2 \), from (26) we have that \( U_2^+ = (C_2,S_2) \). Further from (28) we have that
A New Framework for Analyzing the Inhomogeneous Lighthill-Whitham-Richards Model

\[ U_2(0^+, t) = (D_2(0^+, t), S_2(0^+, t)) \] with \( D_2(0^+, t) \geq S_2 \). Then from (29) we have \( q_{1\to2}(0, t) = \min\{C_1, S_2(0^+, t)\} = S_2 \). Therefore, \( S_2(0^+, t) = S_2 \) and \( D_2(0^+, t) = C_2 \).

When \( D_1 = S_2 \), (30) leads to \( q_{1\to2}(0, t) = D_1 = S_2 \). For link 1, since \( q(U^-) = D_1 \), from (25) we have that \( U_1^- = (D_1, C_1) \). Further from (27) we have that \( U_1(0^-, t) = (D_1(0^-, t), S_1(0^-, t)) \) with \( S_1(0^-, t) \geq D_1^- \geq D_1 \). For link 2, since \( q(U^+) = S_2 \), from (26) we have that \( U_2^+ = (C_2, S_2) \). Further from (28) we have that \( U_2(0^+, t) = (D_2(0^+, t), S_2(0^+, t)) \) with \( D_2(0^+, t) \geq S_2 \).

Then from (29) we have \( q_{1\to2}(0, t) = \min\{D_1(0^-, t), S_2(0^+, t)\} = D_1 = S_2 \). If \( D_1(0^-, t) = D_1 = S_2 \), then \( S_1(0^-, t) = C_1 \), and \( S_2(0^+, t) \geq S_2 \). In this case, the interior state \( U_2(0^+, t) \) may not be unique with \( D_2(0^+, t) \geq S_2 \) and \( S_2(0^+, t) \geq S_2 \). Note that, when \( S_2 = C_2 \), the interior state is \( U_2(0^+, t) = U_2^+ \).

If \( S_2(0^+, t) = D_1 = S_2 \), then \( D_2(0^+, t) = C_2 \), and \( D_1(0^-, t) \geq D_1 \). In this case, the interior state \( U_1(0^-, t) \) may not be unique with \( S_1(0^-, t) \geq D_1 \) and \( D_1(0^-, t) \geq D_1 \). Note that, when \( D_1 = C_1 \), the interior state is \( U_1(0^-, t) = U_1^- \).

If both the upstream link 1 and the downstream link 2 have the same fundamental diagram, this case corresponds to a stationary shock, and the interior state is the same as that in (van Leer 1984).

**Remark 1** From the theorem we can see that the stationary states always exist and are unique for the same pair of \( D_1 \) and \( S_2 \). Thus, with given \( U_1 \) and \( U_2 \), we can find unique kinematic waves on both links 1 and 2. Therefore, in the new solution framework, the solutions for the Riemann problem of the inhomogeneous LWR model always exist and are unique, although we may have multiple interior states.

**Remark 2** If the entropy condition (29) is replaced by (30), we still have the same solutions \( U^-_1 \) and \( U^+_2 \). That is, if we do not consider possible interior states as in (Seguin and Vovelle 2003; Garavello et al. 2007), then traffic conservation (24), admissible conditions for stationary states (25-26), and the entropy condition (30) will yield the same stationary state solutions. However, this simplified approach - which is what currently exists in the literature - does not yield the existence or properties of the interior states.
Remark 3 When $D_1 = S_2$, we have the following interior states that are different from the stationary states at $x = 0^-$ or $x = 0^+$. The interior state at $x = 0^-$ has to satisfy $q(U_1(0^-, t)) \geq D_1$, and the interior state at $x = 0^+$ has to satisfy $q(U_2(0^+, t)) \geq S_2$.

In addition, we have the following conclusions concerning possible stationary states at a linear boundary.

Corollary 1 When both links 1 and 2 reach asymptotic stationary states, they share the same flux $q$, and possible stationary states are the following: both links are UC with link 1 at $(q, C_1)$ and link 2 at $(q, C_2)$ where $q = D_1 < S_2$; both links are OC with link 1 at $(C_1, q)$ and link 2 at $(C_2, q)$ where $q = S_2 < D_1$; link 1 is UC at $(q, C_1)$ and link 2 OC at $(C_2, q)$ where $q = D_1 = S_2$. It is not possible that link 1 is SOC and link 2 SUC.

Remark. The stationary states are stable in the sense that, when they are given as initial states, we obtain the same stationary states following theorem 3.

5.1 The Homogeneous LWR Model

For the original LWR model (2), the upstream link 1 and the downstream link 2 have the same fundamental diagram. Therefore we have $C_1 = C_2$. In (Lebacque 1996), there are four scenarios for solutions to the Riemann problem. Here we reorganize them into the following six cases of initial conditions:

1. Link 1 is SUC, and link 2 is UC. That is, $D_1 < S_1 = C_1$ and $D_2 \leq S_2 = C_2$.

   In this case, $D_1 < S_2$. From theorem 3 we have that $U_1^- = U_1(0^-, t) = U_2^+ = U_2(0^+, t) = U_1$ and $q_{U_1^-}(0, t) = q(U_1)$. Therefore, on link 1, there is no wave; and on link 2, there is a forward shock wave when $D_1 < D_2$, a forward rarefaction wave when $D_1 > D_2$, and no wave when $D_1 = D_2$.

2. Link 1 is OC, and link 2 is UC. That is, $S_1 \leq D_1 = C_1$ and $D_2 \leq S_2 = C_2$.

   In this case, $D_1 = S_2 = C_2$. From theorem 3 we have that $U_1^- = U_1(0^-, t) = U_2^+ = U_2(0^+, t) = (C_1, C_2)$ and $q_{U_1^-}(0, t) = C_1$. Therefore, on link 1, there is a backward rarefaction wave when $S_1 < C_1$ and no wave when $S_1 = C_1$; and on link 2, there is a forward rarefaction wave
when \( D_2 < S_2 \) and no wave when \( D_2 = S_2 \).

3. Link 1 is OC, and link 2 is SOC. That is, \( S_1 \leq D_1 = C_1 \) and \( S_2 < D_2 = C_2 \).

   In this case, \( C_1 = D_1 > S_2 \). From theorem 3 we have that 
   \( U_1^+ = U_1(0^-, t) = U_2^+ = U_2(0^+, t) = U_2 \) and \( q_{1 \to 2}(0, t) = q(U_2) \). Therefore, on link 1 there is a backward shock wave when \( S_1 > S_2 \), a backward rarefaction wave when \( S_1 < S_2 \), and no wave when \( S_1 = S_2 \); and on link 2, there is no wave.

4. Link 1 is SUC, and link 2 is OC, and \( q(U_1) < q(U_2) \). That is, 
   \( D_1 < S_2 \leq D_2 = S_1 = C_1 \). From theorem 3 we have that 
   \( U_1^+ = U_1(0^-, t) = U_2^+ = U_2(0^+, t) = U_1 \) and \( q_{1 \to 2}(0, t) = q(U_1) \). Therefore, on link 1, there is no wave; and on link 2, there is a forward shock wave.

5. Link 1 is SUC, and link 2 is SOC, and \( q(U_1) > q(U_2) \). That is, 
   \( S_2 < D_1 \leq S_1 = D_2 = C_1 \). From theorem 3 we have that 
   \( U_1^+ = U_1(0^-, t) = U_2^+ = U_2(0^+, t) = U_2 \) and \( q_{1 \to 2}(0, t) = q(U_2) \). Therefore, on link 1, there is a backward shock wave; and on link 2, there is a no wave.

6. Link 1 is SUC, and link 2 is SOC, and \( q(U_1) = q(U_2) \). That is, 
   \( D_1 = S_2 < D_2 = S_1 = C_1 \). From theorem 3 we have that 
   \( U_1^+ = U_2^+ = (D_1, S_2) \), and \( q_{1 \to 2}(0, t) = q(U_1) = q(U_2) \). Therefore, on link 1, there is no wave; and on link 2, there is no wave. In this case, there can exist interior states on link 1 or link 2: \( U_1(0^-, t) = U_1^- \) and 
   \( \min\{D_2(0^+, t), S_2(0^+, t)\} \geq D_1 \) or \( U_2(0^+, t) = U_2^+ \) and 
   \( \min\{D_1(0^-, t), S_1(0^-, t)\} \geq D_1 \).

   Obviously the results of stationary states and kinematic waves above are consistent with those in (Lebacque 1996). That is, the new solution framework yields the same wave solutions as traditional approaches.

   The solutions of stationary states for the six cases are also shown in Fig. 7, where figures (a)-(f) are for cases 1-6 respectively. In these figures, both the upstream and downstream links share the same supply-demand diagram. From initial conditions \( U_1 \) and \( U_2 \) we can first draw the pair \( (D_1, S_2) \), from which we can determine upstream and downstream stationary states accordingly. Further we can summarize the solutions of stationary states in Fig. 8 in the \( (D_1, S_2) \) space. This figure also demonstrates a graphical scheme for solving the stationary states as follows. First, from initial \( U_1 \) we draw a vertical line (thin pink line with an ar-
row), from initial \( U_2 \) we draw a horizontal line (thin pink line with an arrow), and the intersection point is \((D_1, S_2)\). Then, if the intersection point is above the line \( 0A \), we draw a vertical line (thick blue line with arrow), and its intersection with \( AC \) gives the stationary states; if the intersection point is below the line \( 0A \), we draw a horizontal line (thick blue line with arrow), and its intersection with \( AC \) gives the stationary states; if the intersection point is on the line \( 0A \), we draw both a vertical line (thick blue line with arrow) and a horizontal line (thick blue line with arrow), and their intersections with \( AC \) are the stationary states for the upstream and the downstream links respectively. Note that this scheme also works when the upstream and downstream links do not have the same fundamental diagrams but the same supply-demand diagram, i.e., \( C_1 = C_2 \).

![Fig. 7. The Riemann problem for the LWR model: stationary states in supply-demand diagrams](image)

5.2 The Inhomogeneous LWR Model

When \( C_1 \neq C_2 \), then the road is inhomogeneous, and there is a discontinuity in the fundamental diagram at \( x = 0 \). In Fig. 9, we demonstrate a graphical scheme for solving stationary states in the \((D_1, S_2)\) space for the inhomogeneous LWR model. We take Fig. 9(a) as an example, in which \( C_1 < C_2 \). First, from initial \( U_1 \)
we draw a vertical line (thin pink line with an arrow), from initial $U_2$ we draw a horizontal line (thin pink line with an arrow), and the intersection point is $(D_1, S_2)$. Then, if the intersection point is above the line $0A$, we draw a vertical line (thick blue line with arrow), and its intersections with $AC_1$ and $AC_2$ are the stationary states on links 1 and 2 respectively; if the intersection point $(D_1, S_2)$ is below the line $0A$, we draw a horizontal line (thick blue line with arrow), and its intersections with $AC_1$ and $AC_2$ are the stationary states on links 1 and 2 respectively; if the intersection point $(D_1, S_2)$ is on the line $0A$, we draw both a vertical line (thick blue line with arrow) and a horizontal line (thick blue line with arrow), and their intersections with $AC_1$ and $AC_2$ are the stationary states for the upstream and the downstream links respectively. This scheme is the same as that for the homogeneous LWR model.

Fig. 8. Solution of stationary states for the Riemann problem for the LWR model

In (Jin and Zhang 2003a), the Riemann problem for the inhomogeneous LWR model was solved as a resonant nonlinear system, and ten types of wave solutions were obtained. For example, wave solutions of Type 1 can be obtained in the new framework as follows. Both $U_1$ and $U_2$ are UC, $D_2 < D_1 \leq C_2 = S_2$, and $C_i$ may be greater or smaller than $C_2$. From Fig. 9 or theorem 3, we can see that
$U_1^- = (D_1, C_1) = U_1$, $U_2^- = (D_1, C_2)$, there is no wave on link 1, there is a forward rarefaction wave on link 2, and $q_{1 \rightarrow 2}(0,t) = q(U_1)$. It is easy to check that the wave solutions of other types are also consistent.

Fig. 9. Solution of stationary states of the Riemann problem for the inhomogeneous LWR model

6. Asymptotic Traffic Dynamics on an Inhomogeneous Ring Road

In this section we consider the inhomogeneous ring road with length $L$ shown in Fig. 10, in which the traffic direction is shown by the arrow. The ring road is composed of two homogeneous links: link 1 with capacity $C_1$ for $x \in [0, L_1]$, link 2 with capacity $C_2$ for $x \in [L_1, L]$, the upstream boundary of link 1 is denoted as boundary 1, and the downstream boundary as boundary 2. Here we assume that link 1 is a bottleneck; i.e., $C_1 < C_2$. For example, such a bottleneck can be caused by a smaller number of lanes. We assume the fundamental relationships for two links as $q = Q_1(\rho)$ and $\rho = R_1(\gamma)$ for $x \in [0, L_1]$, and $q = Q_2(\rho)$ and $\rho = R_2(\gamma)$ for $x \in [L_1, L]$.

When the ring road reaches asymptotic stationary states, the flux at any location is the same, e.g., $q$. As we know, the asymptotic stationary state on a link can be uniformly UC, uniformly SOC, or a stationary shock wave (SS) connecting an upstream SUC state and a downstream SOC state (Bultelle et al. 1998). Then all possible combinations of stationary states are listed in Table 1 and explained in the following.
When link 1 is UC at \((q, C_1)\) with \(q \leq C_1\), we have the following scenarios.

(a) From theorem 3 it is possible that link 2 is UC at \((q, C_2)\), and the total number of vehicles on the ring road is

\[ N_a = R_1(q/C_1)L_1 + R_2(q/C_2)(L - L_1). \]

(b) If link 2 is SS with upstream \((q, C_2)\) and downstream \((C_2, q)\), we have that \(q = C_1\) and link 1 is critical at \((C_1, C_1)\). Assuming that link 2 is SUC for \(x \in [L_1, L_2]\) and SOC for \(x \in [L_2, L]\). In this case, the total number of vehicles on the ring road is

\[ N_b = R_1(1)L_1 + R_2(C_1/C_2)(L_2 - L_1) + R_2(C_2/C_1)(L - L_2). \]

(c) If link 2 is SOC at \((C_2, q)\), we have from theorem 3 that \(q = S_2 = C_1\) at boundary 1. That is, link 1 is critical at \((C_1, C_1)\). In this case, the total number of vehicles on the ring road is

\[ N_c = R_1(1)L_1 + R_2(C_2/C_1)(L - L_1). \]

When link 1 is SOC at \((C_1, q)\) with \(q < C_1\), we have the following scenarios.

(d) It is possible that link 2 is SOC at \((C_2, q)\), and the total number of vehicles on the ring road is

\[ N_d = R_1(C_1/q)L_1 + R_2(C_2/q)(L - L_1). \]

If link 2 is UC at \((q, C_2)\), we have from theorem 3 that \(q = C_1\) at boundary 2. If link 2 is SS with upstream \((q, C_2)\), we have from theorem 3 that \(q = C_1\) at boundary 2. Thus these two scenarios are impossible, since \(q = C_1\) contradicts \(q < C_1\).

When link 1 is SS with upstream \((q, C_1)\) and downstream \((C_1, q)\) with \(q < C_1\), we have the following scenarios. If link 2 is UC at \((q, C_2)\), we have from theorem 3 that \(q = \text{min}\{C_1, C_2\} = C_1\) at boundary 2; if link 2 is SS with upstream \((q, C_2)\), we have from theorem 3 that \(q = \text{min}\{C_1, C_2\} = C_1\) at boundary 2; if link 2 is SOC at \((C_2, q)\), we have from theorem 3 that \(q = \text{min}\{C_2, C_1\} = C_1\) at boundary 1. All three of these scenarios are impossible, since \(q = C_1\) contradicts \(q < C_1\).

For all four scenarios of asymptotic stationary states on the ring road, different scenarios have a different number of vehicles since

\[ 0 \leq N_a \leq R_1(1)L_1 + R_2(C_2/C_1)(L - L_1) < N_b \leq N_c \leq N_d = r_1(1)L_1 + R_2(C_2/C_1)(L - L_1) < N_{d(\infty)} \leq R_1(\infty)L_1 + R_2(\infty)(L - L_1). \]

Due to traffic conservation on the ring road, we can therefore determine the final stationary states by the initial number of vehicles \(N\) on the road as follows: (a) When \(N \leq R_1(1)L_1 + R_2(C_1/C_2)(L - L_1)\), links 1 and 2 will be asymptotically
stationary at UC with \((q, C_1)\) and \((q, C_2)\) respectively, where \(q\) is the solution of
\[ R_1(q/C_1)L_1 + R_2(q/C_2)(L - L_1) = N \]; (b) When \(R_1(1)L_1 + R_2(C_1/C_2)(L - L_1) < N < R_1(1)L_1 + R_2(C_2/C_1)(L - L_1)\), link 1 will be asymptotically stationary at critical with \((C_1, C_1)\), and link 2 at SS with \((C_1, C_2)\) for \(x \in [L_1, L_2]\) and \((C_2, C_1)\) for \(x \in (L_2, L]\), where \(L_2\) is the solution of
\[ R_1(1)L_1 + R_2(C_1/C_2)(L_2 - L_1) + R_2(C_2/C_1)(L - L_2) = N \]; (c) When \(N = R_1(1)L_1 + R_2(C_2/C_1)(L - L_1)\), link 1 will be asymptotically stationary at critical with \((C_1, C_1)\), and link 2 at SOC with \((C_2, C_1)\); (d) When \(N > R_1(1)L_1 + R_2(C_2/C_1)(L - L_1)\), links 1 and 2 will be asymptotically stationary at SOC with \((C_1, q)\) and \((C_2, q)\) respectively, where \(q\) is the solution of
\[ R_1(C_1/q)L_1 + R_2(C_2/q)(L - L_1) = N \].

From theorem 3, an interior state can occur at a boundary when its upstream demand equals the downstream supply, and its flux cannot be smaller than the demand or supply. In the following we consider possible asymptotic interior states on the ring road in Fig. 10. First, at any location inside a uniform traffic stream on a homogeneous road, it is not possible to have interior states, since the upstream and downstream states are exactly the same at \((D, S)\) and \(D = S\) if and only if the traffic is \(D = S = C\), in which case the interior states have to be the same as the stationary states. Thus, interior states can only exist around the interface between two uniform traffic streams when the upstream demand equals the downstream supply, and we examine possible interior states in all four scenarios as follows. (a) The necessary condition for an interior state to exist at boundary 1 is \(q = C_1\), i.e., when \(N = R_1(1)L_1 + R_2(C_1/C_2)(L - L_1)\). From theorem 3, the interior state can only exist at \(x = 0^-\), but not \(x = 0^+\). The necessary condition for an interior state to exist at boundary 2 is \(q = C_2\), which is not possible. (b) It is not possible for interior states to exist at either boundary 1 or 2, but it is possible for an interior state to exist around the SS interface at \(x = L_2\). From theorem 3, the interior state can only exist at \(x = L_2^-\) or \(x = L_2^+\). (c) It is not possible for an interior state to exist at boundary 1, but it is possible for an interior state to exist around boundary 2. That is, when \(N = R_1(1)L_1 + R_2(C_1/C_2)(L - L_1)\), from theorem 3, the interior state can only exist at \(x = L_1^+\), but not \(x = L_1^-\). (d) It is not possible for interior states to exist at either boundary 1 or 2.

In summary, there can exist three types of interior states: (a) When \(N = N_1 = R_1(1)L_1 + R_2(C_1/C_2)(L - L_1)\), an interior state can only exist at
When \( R_1(1)L_1 + R_2(C_1/C_2)(L - L_1) < N < R_1(1)L_1 + R_2(C_2/C_1)(L - L_1) \), an interior state can exist at \( x = L_2^- \) or \( x = L_2^+ \); (c) When \( N = N_3 = R_1(1)L_1 + R_2(C_2/C_1)(L - L_1) \), an interior state can only exist at \( x = L_1^- \).

6.2 Numerical Examples

In this subsection, we study asymptotic traffic dynamics on the inhomogeneous ring road in Fig. 10 with \( L = 600l = 16.8 \text{ km} \), \( l_1 = 100l = 2.8 \text{ km} \), and the location-dependent speed-density relationships are based on (Kerner and Konhauser 1994; Herrmann and Kerner 1998)

\[
V(\rho, a(x)) = 5.0461 \left[ 1 + \exp \left\{ \frac{\rho}{a(x)\rho_j} - 0.25 \right\} \right]^{-1} - 3.72 \times 10^{-6} /\tau,
\]

where the relaxation time \( \tau = 5 \text{ s} \); the unit length \( l = 0.028 \text{ km} \); the free flow speed \( v_f = 27.8 \text{ m/s} \); the jam density of a single lane \( \rho_j = 180 \text{ veh/km/lane} \). Here the number of lanes \( a(x) = 1 \) for link 1 and \( a(x) = 2 \) for link 2. The corresponding fundamental diagram \( q = Q(\rho, a(x)) \) is non-convex but unimodal in density \( \rho \). In addition, \( C_1 = 0.7091 \text{ veh/s} \), and \( C_2 = 2C_1 \). Thus we can compute \( R_1(1) = 35.8944 \text{ veh/km} \), \( R_2(C_1/C_2) = R_2(1) = 26.4162 \text{ veh/km} \), and \( R_2(C_2/C_1) = R_2(2) = 118.3550 \text{ veh/km} \). Hence

\[
N_1 = R_1(1)L_1 + R_2(C_1/C_2)(L - L_1) = 470.3311 \text{ veh},
\]

\[
N_3 = R_1(1)L_1 + R_2(C_2/C_1)(L - L_1) = 1757.4746 \text{ veh}.
\]

Here we consider the following initial condition:

\[
\rho(x, 0) = a(x)(\rho_0 + 3\sin \frac{2\pi x}{L}), \quad x \in [0, L],
\]

\[
v(x, 0) = V(\rho(x, 0), a(x)), \quad x \in [0, L]. \tag{43}
\]

Then, the total number of vehicles on the ring road is

\[
N = 2\rho_0L - \int_0^{100l} (\rho_0 + 3\sin \frac{2\pi x}{L})dx = 1100l\rho_0 - \frac{450}{\pi} l.
\]
When $\rho_0 = 15.4007$ veh/km, $N = N_1$ and we observe an interior state at $x = 0^- = L^-$; when $\rho_0 = 57.1911$ veh/km, $N = N_3$ and we observe an interior state at $x = L^+_1$; when $\rho_0 \in (15.4007, 57.1911)$, we observe an interior state at $x = L^-_2$ or $x = L^+_2$, where $L_2$ is the solution of $R_1(1)L_1 + R_2(\frac{1}{2})(L_2 - L_1) + R_2(2)(L - L_2) = N$. For example, when $\rho_0 = 28$ veh/km, $N = 858.3893$ veh, and

$$L_2 = \frac{N - (R_1(1) - R_2(\frac{1}{2}))L_1 - R_2(2)L}{R_2(\frac{1}{2}) - R_2(2)} = 449.2561\text{l}.$$ 

**Fig. 11.** Solutions of $\rho$, $v$, and $q$ at $T = 24000$ s for initial conditions in (31): solid lines with stars for $\rho_0 = 15.4007$ veh/km, dashed lines with circles for $\rho_0 = 28$ veh/km, and dash-dotted lines for $\rho_0 = 57.1911$.

In the following, we simulate traffic dynamics on the ring road for three different initial $\rho_0$: 15.4007 veh/km, 28 veh/km, and 57.1911 veh/km. Here we use the Godunov finite difference equation in (18) and the supply-demand method in (19).
for computing boundary fluxes. The simulation time is \( T = 4800 \tau = 24000 \) s. We partition the road \([0, L]\) into \( N = 4800\) cells and the time interval \([0, T]\) into \( K = 240000\) steps. Hence, the length of each cell is \( \Delta x = 3.5\) m and the length of each time step is \( \Delta t = 0.1\) s. The CFL condition number (Courant et al. 1928) is

\[
\frac{v}{\Delta x} \leq 0.79 < 1.
\]

The results for the three initial conditions are shown in Fig. 11, where the bottom figure shows the locations and fluxes of all three interior states. From the figure, we can see that each of the three interior states only exists in one cell, and the locations of interior states are exactly as predicted above. Note that the top right figure of Fig. 18 in (Jin and Zhang 2003a) also demonstrates the existence of an interior state, which is at the interface of a stationary shock.

7. Conclusion

In this paper we first reviewed the definitions of the supply and demand functions and the discrete supply-demand method for computing boundary fluxes. We then introduced the supply-demand diagram of a roadway and a new framework for solving the Riemann problem of the inhomogeneous LWR model in supply-demand space. In this framework, each link can have asymptotic interior and stationary states near the boundary, and the wave on each link is determined by the Riemann problem of the homogeneous LWR model with stationary and initial states for initial conditions. We have derived conditions for admissible stationary and interior states and introduced an entropy condition based on the discrete supply-demand method for computing boundary fluxes. We then proved that solutions to the Riemann problem exist and are unique and demonstrated that these solutions are consistent with those in literature for both the homogeneous and inhomogeneous LWR models. We also presented a graphical approach for finding the asymptotic stationary states with the help of supply-demand diagrams. Finally, we discussed the asymptotic stationary states on a ring road with arbitrary initial conditions and demonstrated with numerical examples that the existence and properties of the interior states are as predicted in this framework.

Unlike existing studies of the homogeneous or inhomogeneous LWR models, this study analyzes traffic dynamics in supply-demand space. In this framework, the discrete supply-demand method is applied as an entropy condition. In this sense, our study provides a new approach for constructing convergent solutions of finite difference equations arising in a Godunov method (18) with a supply-demand method (19) for both the homogeneous and inhomogeneous LWR models. We have demonstrated that this new approach can successfully predict the existence and properties of interior states in numerical solutions. However, note that interior states take only one cell in numerical solutions and diminish.
the cell size. In this sense, the interior states are inconsequential to solutions of the Riemann problem.

Compared with existing studies, the new approach in the supply-demand framework is much simpler. In addition, since supply-demand methods have been proposed for computing fluxes through other junctions in general road networks (Daganzo 1995a; Lebacque 1996; Jin and Zhang 2003b; Jin 2003), our framework could be extended to constructing solutions to the Riemann problem in these models. In (Jin 2009), we successfully applied this framework to analyze the Riemann problem of merging traffic flow. In addition, one could also apply this new framework to analyze asymptotic traffic dynamics in a road network, such as the diverge-merge network studied in (Jin 2008).
