LONG TIME SOLUTIONS FOR A BURGERS-HILBERT EQUATION VIA A MODIFIED ENERGY METHOD

JOHN K. HUNTER, MIHAELA IFRIM, DANIEL TATARU, AND TAK KWONG WONG

Abstract. We consider an initial value problem for a quadratically nonlinear inviscid Burgers-Hilbert equation that models the motion of vorticity discontinuities. We use a modified energy method to prove the existence of small, smooth solutions over cubically nonlinear time-scales.

1. Introduction

We consider the following initial value problem for an inviscid Burgers-Hilbert equation for \( u(t, x) \):

\[
\begin{align*}
  u_t + uu_x &= H[u], \\
  u(0, x) &= u_0(x),
\end{align*}
\]

(1)

where \( H \) is the spatial Hilbert transform on \( \mathbb{R} \), and the initial data \( u_0 \) is sufficiently small

\[ \|u_0(x)\|_{H^2(\mathbb{R})} \leq \epsilon \ll 1. \]

Here, \( H^k(\mathbb{R}) \) denotes the standard Sobolev space of functions with \( k \) weak \( L^2 \)-derivatives.

Equation (1) was proposed in [1] as a model equation for nonlinear waves with constant frequency. It also provides a formal asymptotic approximation for the small-amplitude motion of a planar vorticity discontinuity located at \( y = u(t, x) \) [1, 5]. Moreover, even though the equation is quadratically nonlinear, this approximation is valid over cubically nonlinear time-scales.

Equation (1) is nondispersive, and solutions of the linearized equation oscillate in time but do not exhibit any dispersive decay. Nevertheless, in comparison with the inviscid Burgers equation, small smooth solutions of (1) have an enhanced, cubically nonlinear lifespan. This enhanced lifespan was observed numerically in [1] and proved in [2] by use of a change of the independent variable, which was suggested by a normal form transformation of the equation.

In this paper we give a different, and simpler, proof of the enhanced lifespan of smooth solutions of (1) from the one in [2]. Our main result is the following theorem:

Theorem 1. a) Let \( k \geq 2 \). Suppose that the initial data \( u_0 \in H^k(\mathbb{R}) \) for the equation (1) satisfies

\[ \|u_0\|_{H^2(\mathbb{R})} \leq \epsilon \ll 1. \]
Then there exists a solution \( u \in C (I^*; H^k (\mathbb{R})) \cap C^1 (I^*; H^{k-1} (\mathbb{R})) \) of (1) defined on the time-interval \( I^* = [-\alpha/\epsilon^2, \alpha/\epsilon^2] \), where \( \alpha > 0 \) is a universal constant, so that
\[
\| u \|_{L^\infty (I^*; H^s (\mathbb{R}))} \lesssim \| u(0) \|_{H^s (\mathbb{R})}, \quad 0 \leq s \leq k.
\]

b) Consider \( u_1, u_2 \) two solutions of (1) as in part (a). Then
\[
\| u_1 - u_2 \|_{L^\infty (I^*; L^2 (\mathbb{R}))} \lesssim \| u_1(0) - u_2(0) \|_{L^2 (\mathbb{R})}.
\]

The quadratically nonlinear terms in (1) are non-resonant, and a standard approach for problems of this type is to use a normal form transformation (see for instance [7]) to remove them. However, this is a quasi-linear problem, so the normal form transformation is unbounded, and this method cannot be applied directly. Our alternative approach is to use the normal form transformation in order to derive a modified energy functional for the original problem (1) which evolves according to a cubic law.

The same modified energy method also applies to the linearization of the Burgers-Hilbert equation, and allows us to control differences of solutions on a cubic timescale.

We remark that with some additional work one can replace the \( H^2 \) norm for the data in part (a) of the above theorem with \( H^{s_0} \) for any \( s_0 > 3/2 \). Similarly, the \( L^2 \) norm in part (b) can be replaced by \( H^s \) for a smaller range \( 0 \leq s \leq s_0 - 1 \).

2. The Normal Form Transformation

Straightforward energy estimates applied to (1) yield
\[
\frac{d}{dt} \| \partial_x^k u \|_{L^2}^2 \lesssim \| u_x \|_{L^\infty} \| u \|_{H^k}^2
\]
for \( k \geq 2 \), which gives a lifespan of smooth solutions of the order \( \epsilon^{-1} \), as in the standard local existence theory for quasi-linear hyperbolic PDEs [3, 4].

The quadratically nonlinear terms in (1) can be removed by a normal form transformation [1, 2]
\[
(2) \quad v = u + H [Hu \cdot Hu_x].
\]
The transformed equation has the form
\[
(3) \quad v_t + Q(u) = H [v]
\]
where \( Q(u) \) is cubic in \( u \) but involves two spatial derivatives. Straightforward energy estimates for (3) yield
\[
\frac{d}{dt} \| \partial_x^k v \|_{L^2}^2 \lesssim \| u_x \|_{L^\infty}^2 \| u \|_{H^{k+1}}^2.
\]
However, since the above normal form transformation is not invertible, the energy estimates for \( v \) do not close. Thus, the \( v \)-equation is cubically nonlinear, but there is a loss of derivatives. On the other hand, the \( u \)-equation is quadratically nonlinear, but there is no loss of derivatives.

The reason for this disparity in energy estimates is that the \( H^k \)-norms of \( u \) and \( v \) are not comparable. From (2), we have
\[
\| \partial_x^k v \|_{L^2}^2 = \| \partial_x^k u \|_{L^2}^2 + 2 \langle \partial_x^k u, \partial_x^k H [Hu \cdot Hu_x] \rangle + \| \partial_x^k H [Hu \cdot Hu_x] \|_{L^2}^2.
\]
The second term on the right-hand side of (4) is comparable to the $H^k$-norm of $u$ because
\[
\langle \partial_x^k u, \partial_x^k (H u \cdot H u_x) \rangle = \left( k + \frac{1}{2} \right) \langle H u_x, (\partial_x^k H u)^2 \rangle + \text{l.o.t.}
\]
where l.o.t. stands for lower order terms. The third term on the right-hand side of (4) is not comparable to the $H^k$-norm, but it is quartic and therefore irrelevant to the cubically nonlinear energy estimates.

This discussion suggests that we define a modified energy functional by dropping the higher-derivative quartic term from the right-hand side of (4) to get
\[
E_k(u) = \frac{1}{2} \| \partial_x^k u \|_{L^2}^2 + \langle \partial_x^k u, \partial_x^k (H u \cdot H u_x) \rangle.
\]
As we will show, this modified energy is equivalent to the standard $H^k$-energy and satisfies cubically nonlinear estimates without a loss of derivatives.

3. The Modified Energy Method

In this section, we use the modified energy functional introduced in (5) to prove Theorem 1. We first show that $E_k$ energy is equivalent to the standard $H^k$ energy.

**Lemma 2.** Let $E_k$ be defined by (5). Then
\[
E_k(u) = \frac{1}{2} \| \partial_x^k u \|_{L^2}^2 + \langle \partial_x^k u, \partial_x^k (H u \cdot H u_x) \rangle + O(\|H u_x\|_{L^\infty}).
\]

**Proof.** Denote
\[
T_u f := H[H u \cdot H f_x].
\]
This operator is essentially skew-adjoint. Moreover, we have
\[
\langle f, T_u f \rangle = -\langle H f, H u \cdot H f_x \rangle
= \frac{1}{2} \int_\mathbb{R} H u_x |H f|^2 dx = O(\|H u_x\|_{L^\infty}) \|f\|_{L^2}^2.
\]

We write
\[
\partial_x^k (H u \cdot H u_x) = T_u \partial_x^k u + \text{l.o.t.}
\]
where l.o.t. stands for terms of the form $H[\partial_x^j H u_x \cdot \partial_x^{k-1-j} H u_x]$ with $0 \leq j \leq k-1$.

For the leading term we use the previous estimate for $T_u$, and for the lower order terms we use interpolation,
\[
\|\partial_x^j H u_x \cdot \partial_x^{k-1-j} H u_x\|_{L^2} \lesssim \|H u_x\|_{L^\infty} \|\partial_x^{k-1} u_x\|_{L^2}
\]
Thus, we obtain
\[
\langle \partial_x^k u, \partial_x^k (H u \cdot H u_x) \rangle = O(\|H u_x\|_{L^\infty}) \|\partial_x^k u\|_{L^2}
\]
\]

The energy estimate is discussed in the following lemma:

**Lemma 3.** For the energy (5) the estimate below holds: for any $\delta > 0$,
\[
\frac{d}{dt} E_k(u) \leq C_{k,\delta} \|u_x\|_{H^{1+\delta}}^2 \|u\|_{H^k}^2
\]
where $C_{k,\delta}$ is a constant depending on $k$ and $\delta$ only.
Proof. A direct computation yields

\[-\frac{d}{dt} E_k(u) = \int_{\mathbb{R}} \partial_x^k (uu_x) \partial_x^k H [Hu \cdot Hu_x] \, dx + \int_{\mathbb{R}} \partial_x^k u \{ \partial_x^k H [Hu \cdot Hu_x] + \partial_x^k H [Hu \cdot H[uu_x]] \} \, dx.\]

Note that all cubic terms cancel. This is because the energy was determined using the normal form transformation, which at the level of the energy amounts to eliminating the cubic terms. Using the antisymmetry of \( H \) and integrating by parts we rewrite the above expression in the form

\[-\frac{d}{dt} E_k(u) = \int_{\mathbb{R}} -\partial_x^k H (uu_x) \partial_x^k [Hu \cdot Hu_x] + \partial_x^k H u_x \partial_x^k [Hu \cdot H(uu_x)] \, dx.\]

We observe that in each term in the expansion of the above integrand has the form

\[H \partial^\alpha u H \partial^\beta u H(\partial^\gamma u \partial^\delta u)\]

where

\[\alpha + \beta + \gamma + \delta = 2k + 2\]

We observe that as long as

\[1 \leq \alpha, \beta, \gamma, \delta \leq k, \quad \alpha + \beta \geq 3, \delta + \gamma \geq 3\]

such terms can be estimated directly in terms of the right hand side of the energy relation in the Lemma. We will call such terms “good”.

We return to the expression above, and observe that a cancellation occurs if the second \( \partial_x^k \) operator in each of the two expressions applies to the second factor. Using a full binomial expansion, we are left with the expressions

\[I_\alpha = \int_{\mathbb{R}} -\partial_x^k H (uu_x) \cdot \partial_x^\alpha Hu \cdot \partial_x^{k-\alpha} Hu_x + \partial_x^k H u_x \cdot \partial_x^\alpha Hu \cdot \partial_x^{k-\alpha} H(uu_x) \, dx\]

where \(1 \leq \alpha \leq k\). Distributing the remaining derivatives, we get good terms if any derivatives fall on the \( u \) factor (an additional integration by parts is needed to see this for the second term). Thus we have

\[I_\alpha = \int_{\mathbb{R}} -[H, u] \partial_x^k u_x \cdot \partial_x^\alpha Hu \cdot \partial_x^{k-\alpha} Hu_x + \partial_x^k H u_x \cdot \partial_x^\alpha Hu \cdot [H, u] \partial_x^{k-\alpha} u_x \, dx + \text{good}.\]

If \( u \) is commuted out the two expressions above cancel. Hence

\[I_\alpha = \int_{\mathbb{R}} -[H, u] \partial_x^k u_x \cdot \partial_x^\alpha Hu \cdot \partial_x^{k-\alpha} Hu_x + \partial_x^k H u_x \cdot \partial_x^\alpha Hu \cdot [H, u] \partial_x^{k-\alpha} u_x \, dx + \text{good}.\]

The commutator \([H, u]f\) vanishes unless the frequency of \( u \) is at least as large as the frequency of \( f \). Hence we can always move derivatives from \( f \) onto \( u \). Then for the first term in \( I_\alpha \) we can use directly the commutator estimate below:

\[(6) \quad \| [H, u] \partial_x^k u_x \|_{L^2} \lesssim \|u_x\|_{L^\infty} \|\partial_x^k u\|_{L^2}.\]

This is a consequence of the commutator estimates result obtained by Dawson, McGahagan, and Ponce in [6]. We recall it below:

**Lemma 4.** Let \( H \) denote the Hilbert transform. Then for any \( p \in (1, \infty) \) and any \( l, m \in \mathbb{Z}^+ \) there exists \( c = c(p, l, m) > 0 \) such that

\[\| \partial_x^l [H, a] \partial_x^m f \|_{L^p} \leq c \|\partial_x^{l+m} a\|_{L^\infty} \|f\|_{L^p}.\]
For the second in $I_\alpha$ we need to integrate once by parts since the first factor has too many derivatives. If $\alpha < k$ this is done directly. If $\alpha = k$ then we move a derivative on the third factor. We are left with two terms which are nontrivial, namely

$$J_k := \int |\partial_x^k H u|^2[H, u_x]u_x dx$$

and

$$J_{k-1} := \int |\partial_x^k H u|^2[H, u]u_x dx.$$

For these we need the pointwise bound

$$\| [H, u_x] u_x \|_{L^\infty} + \| [H, u] u_{xx} \|_{L^\infty} \lesssim u_x^2_{H^{\frac{1}{2} + \delta}}.$$  \hfill (7)

Indeed, both terms on the left can be estimated in $H^{\frac{1}{2} + \delta}$ using standard Littlewood-Paley decompositions.

By a Gronwall type argument, the two lemmas above lead to an $\epsilon^{-2}$ lifespan, proving part (a) of Theorem 1.

Next, in order to prove part (b) of Theorem 1, we consider the linearized Burgers-Hilbert equation:

$$w_t + wu_x + uw_x = Hw. \hfill (8)$$

Beginning with the normal form transformation (2) for the Burgers-Hilbert equation, we obtain the normal form transformation for the linearization (8):

$$q := w + |\partial_x|(Hw \cdot Hu).$$

where $|\partial_x| = H \circ \partial_x$. Inspired by this we can define a modified linearized energy

$$E_{lin}(w) = \int w^2 + 2|\partial_x|w \cdot Hu \cdot Hw \, dx.$$  \hfill (9)

This is equivalent to the $L^2$ norm of $w$,

$$E_{lin}(w) = (1 + O(\| H u_x \|_{L^\infty})\| w \|_{L^2}^2.$$  

This is proved using integration by parts in order to write

$$E_{lin}(w) = \int w^2 - |\partial_x|u \cdot (Hw)^2 \, dx.$$  

We want to prove that $E_{lin}$ satisfies good cubic bounds; a Gronwall type argument implies part (b) of Theorem 1.

**Lemma 5.** For the energy (9) the estimate below holds: for any $\delta > 0$,

$$\frac{d}{dt} E_{lin}(w) \leq C_{k, \delta} \| u_x \|_{H^{\frac{1}{2} + \delta}}^2 \| w \|_{L^2}^2,$$

where $C_{k, \delta}$ is a constant depending on $k$ and $\delta$ only.

**Proof.** A straightforward computation leads to

$$\frac{d}{dt} E_{lin}(w) = \int 2Hw \cdot H[wu_x] \cdot Hu_x + 2Hw \cdot H[ww_x] \cdot Hu_x + |Hw|^2 \cdot |\partial_x|(wu_x) \, dx$$

$$= \int 2Hw \cdot H[wu_x] \cdot Hu_x + 2Hw \cdot [H, u] \partial_x w \cdot Hu_x + |Hw|^2 \partial_x ([H, u] \partial_x u) \, dx.$$
The first term is estimated directly and for the second we use the commutator bound \([6]\). The third term can be controlled because we can rewrite
\[
\partial_x ([H, u] \partial_x u) = [H, u_x] \partial_x u + [H, u] \partial_x^2 u,
\]
where the right hand side can be estimated by the pointwise bound \([7]\). □
