# Higher-Order Graph Signals

Recently there has been great interest in analyzing and processing signals measured on *higher-order networks*.

- Data are sampled over  $C_k$ , oriented *k-simplices* of a graph,  $k \in \mathbb{N}$ :
- For  $k = 0, 1, 2, 3, \dots$ , these signals take values over *nodes*, *edges*, *triangles*, *tetrahedra*, ..., respectively.
- Examples: regional weather data, molecular chemistry, neuronal networks, social networks, discrete exterior calculus/geometry, ...

Flows around Madagascar [Schaub et al. (2020)]

Gene expression correlations [Govek et al. (2019)]

Coauthorship graph [Ebli et al. (2022)]

# Roadmap So Far

- We have developed the graph versions of the *local cosine and wavelet packet dictionaries* for analysis of graph signals *sampled at nodes*.
- All these are based on the *hierarchical bipartitioning* of either a primary graph  $G$  or the so-called *dual graph*  $G^*$ .  $\Omega :=$  a domain to be hierarchically bipartitioned:

Classical Basis Dict.	$\Omega$		Graph Basis Dict.	$\Omega$
Hierarchical Block DCT	time axis		<i>HGLET</i>	$G$
Local Cosine Transform	time axis		<i>LP-HGLET</i>	$G$
Haar-Walsh Wavelet Packets	time/freq. axes		<i>GHWT/eGHWT</i>	$G$
Compactly-Supported Wavelet Packets	frequency axis		<i>LP-NGWPs</i>	$G^*$
Shannon Wavelet Packets	frequency axis		<i>NGWPs</i>	$G^*$

HGLET := Hierarchical Graph Laplacian Eigen Transform [Irion-Saito (2014)];

GHWT := Generalized Haar-Walsh Transform [Irion-Saito (2014)];

eGHWT := extended GHWT [Saito-Shao (2022)];

NGWPs := Natural Graph Wavelet Packets [Cloninger-Li-Saito (2021)];

LP-HGLET/NGWPs := Lapped-HGLET/NGWPs [Li (2021)]

Underlying Philosophy/Basso Continuo:

Split  $\Rightarrow$  "Organize"  $\Rightarrow$  Merge

# Representing Higher-Order Graphs

- A *simplicial complex*,  $C$ , represents a combinatorial description of a topological space that can be represented and handled by a computer.
- The  $k$ -simplices  $C_k \subset C$  are typically captured by *boundary matrices*  $B_{k-1}, B_k$  expressing adjacency and relative orientation of each  $k$ -simplex  $\sigma$  with each  $(k-1)$ -simplex  $\alpha$  or  $(k+1)$ -simplex  $\beta$  respectively.
- The orientations may be given by the nature of the data, or need to be specified by the user.

$$[B_{k-1}]_{\alpha\sigma} = \begin{cases} 1 & \alpha, \sigma \text{ have consistent orientation} \\ -1 & \alpha, \sigma \text{ have inconsistent orientation} \\ 0 & \text{otherwise} \end{cases} \quad [B_k]_{\sigma\beta} = \begin{cases} 1 & \sigma, \beta \text{ have consistent orientation} \\ -1 & \sigma, \beta \text{ have inconsistent orientation} \\ 0 & \text{otherwise} \end{cases}$$

# Hodge Laplacian

- The *Hodge Laplacian* (aka *k-Laplacian*) [see, e.g., L.-H. Lim: *SIAM Review* (2020); M. T. Schaub et al.: *Signal Process.* (2021)] provides a spectral decomposition for a signal measured on  $k$ -simplices in a given simplicial complex.
- Since the  $k$ -Laplacian has both “upper” and “lower” parts, we need a new notion of *neighbors*: two  $k$ -simplices are *adjacent* if they either:
  - ▶ have a  $(k - 1)$ -simplex in common as a face; or
  - ▶ are both faces of some  $(k + 1)$ -simplex in the complex.

## Hodge Laplacian via Boundary Matrices

$$L_k := B_{k-1}^\top B_{k-1} + B_k B_k^\top; \quad D_k := \text{diag}(L_k)$$

# 2-Simplicial Path

$$B_0 = \begin{bmatrix} -1 & -1 & 0 & 0 & & 0 & 0 & 0 \\ 1 & 0 & -1 & -1 & \dots & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & & 0 & 0 & 0 \\ \vdots & & & & \ddots & & & \vdots \\ 0 & 0 & 0 & 0 & & -1 & -1 & 0 \\ 0 & 0 & 0 & 0 & \dots & 1 & 0 & -1 \\ 0 & 0 & 0 & 0 & & 0 & 1 & 1 \end{bmatrix}$$

$$B_1 = \begin{bmatrix} -1 & 0 & 0 & & 0 & 0 \\ 1 & 0 & 0 & \dots & 0 & 0 \\ -1 & -1 & 0 & & 0 & 0 \\ 0 & 1 & 0 & & 0 & 0 \\ 0 & 0 & -1 & 0 & 0 & 0 \\ \vdots & & & \ddots & & \vdots \\ 0 & 0 & 0 & & 0 & -1 \\ 0 & 0 & 0 & \dots & 0 & 1 \\ 0 & 0 & 0 & & 0 & -1 \end{bmatrix}$$

$$B_2 = O$$

$$L_0 = B_0 B_0^T = \begin{bmatrix} 2 & -1 & -1 & 0 & & 0 & 0 & 0 \\ -1 & 3 & -1 & -1 & \dots & 0 & 0 & 0 \\ -1 & -1 & 4 & -1 & & 0 & 0 & 0 \\ 0 & -1 & -1 & 4 & & 0 & 0 & 0 \\ \vdots & & & & \ddots & & & \vdots \\ 0 & 0 & 0 & 0 & & 4 & -1 & -1 \\ 0 & 0 & 0 & 0 & \dots & -1 & 3 & -1 \\ 0 & 0 & 0 & 0 & & -1 & -1 & 2 \end{bmatrix}$$

$$L_1 = B_0^T B_0 + B_1 B_1^T = \begin{bmatrix} 3 & 0 & 0 & -1 & & 0 & 0 \\ 0 & 3 & 0 & 0 & \dots & 0 & 0 \\ 0 & 0 & 4 & 0 & & 0 & 0 \\ -1 & 0 & 0 & 3 & & 0 & 0 \\ \vdots & & & & \ddots & & \vdots \\ 0 & 0 & 0 & 0 & \dots & 3 & 0 \\ 0 & 0 & 0 & 0 & & 0 & 3 \end{bmatrix}$$

$$L_2 = B_1^T B_1 = \begin{bmatrix} 3 & 1 & 0 & \dots & 0 \\ 1 & 3 & 1 & \ddots & \vdots \\ 0 & 1 & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & 3 & 1 \\ 0 & \dots & 0 & 1 & 3 \end{bmatrix} \text{ symmetric tridiagonal Toeplitz!}$$

# Hodge-Laplacian Eigenvectors

(a)  $k = 0$

(b)  $k = 1$

(c)  $k = 2$  (DST-I)

# Weighted and Normalized Hodge Laplacian

Weighted Graph Laplacian

$$L_0 = B_0 D_1 B_0^\top$$

Weighted Hodge Laplacian

$$L_k = (B_{k-1} D_k)^\top D_{k-1}^{-1} (B_{k-1} D_k) + B_k D_{k+1} B_k^\top$$

Random-Walk Normalization

$$L_0^{\text{rw}} = D_0^{-1} L_0$$

Random-Walk Normalization

$$L_k^{\text{rw}} = D_k^{-1} L_k$$

Symmetric Normalization

$$L_0^{\text{sym}} = D_0^{-1/2} L_0 D_0^{-1/2}$$

Symmetric Normalization

$$L_k^{\text{sym}} = D_k^{-1/2} L_k D_k^{-1/2}$$

# Bipartitioning Simplicial Complexes

- The graph Laplacian  $L_0^{\text{rw}}$  admits a *Fiedler vector* (i.e., the eigenvector  $\phi_1$  corresponding to the second smallest eigenvalue  $\lambda_1$ ), whose sign provides a bipartition of nodes ( $\mathbf{0}$ -simplices) minimizing a relaxed version of *Normalized Cut*.
- The Hodge Laplacian  $L_k^{\text{rw}}$  also admits a *Fiedler vector* whose sign provides a bipartition of  $k$ -simplices minimizing a relaxed version of a cut objective function related to the Normalized Cut.
- Unlike  $L_0^{\text{rw}}$ , however, the components of  $\phi_0$  of  $L_k^{\text{rw}}$ ,  $k \geq 1$ , may change their signs in general; hence  $\phi_1 \odot \text{sign}(\phi_0)$  provides the Fiedler vector.
- Be careful about the multiplicity of  $\mathbf{0}$  eigenvalues (aka the *Betti number* = # of “ $k$ -dimensional holes”) !  $\implies$  the Fiedler vector should be  $\phi_{\beta_{k+1}} \odot \text{sign}(\phi_{\beta_k})$ .
- Any other good bipartition method for simplicial complexes can be used for building our multiscale basis dictionaries.

# Hierarchical Bipartitioning

A synthetic simplicial complex with  $k = 2$ . Successively bipartitioning the subcomplexes induced by prior partitions leads to finer, nicely localized domains, illustrated by piecewise-constant functions on the triangles. Proceeding left-to-right, each complex has been bipartitioned to one finer level.

# Hierarchical Graph Laplacian Eigen Transform (HGLET)

can be viewed as a *generalization of the Hierarchical Block DCT dictionary* and be generated as follows [Irion-S. (2014)]:

1. Partition the graph into two subgraphs
  2. Compute the graph Laplacian of each subgraph
  3. Form an ONB for each subgraph via the eigensystem
  4. Continue the above steps recursively until each subgraph becomes a single node
- The HGLET dictionary, i.e., resulting set of  $\approx n(1 + \log_2 n)$  basis vectors, contains more than  $O(1.5^n)$  ONBs  $\implies$  the *best basis* and its relatives can be selected!
  - The HGLET can be further generalized for  $k$ -simplices using the eigenvectors of the *Hodge Laplacians* via bipartitions, which we call *k-HGLET* [S.-Schonsheck-Shvarts (2024)].

# The 2-HGLET Dictionary on the Triangle Complex

Each row represents one level of the bipartition

# Generalized Haar-Walsh Transform (GHWT)

is a *generalization of the classical Haar-Walsh wavelet packet dictionary* for the graph setting [Irion-S. (2014)]:

1. Recursively bipartition the graph via any method until each subgraph becomes a single node
  2. Construct an ONB at the bottom/finest level using the standard basis of  $\mathbb{R}^n$ , which are *scaling* vectors at that level
  3. Generate an ONB for the immediate upper level by the sum and difference operators, which become the scaling and the *Haar* vectors, respectively
  4. Repeat this process until it reaches the top/coarsest level, which generates the scaling, Haar, and *Walsh* vectors at each level
- The GHWT dictionary, i.e., the resulting set of  $\approx n(1 + \log_2 n)$  basis vectors, contains more than  $O(1.5^n)$  ONBs  $\implies$  the *best basis* and its relatives can be selected!
  - The GHWT can be further generalized for  $k$ -simplices via recursive bipartitions, which we call *k-GHWT* [S.-Schonsheck-Shvarts (2024)].

# The Coarse-to-Fine GHWT Dictionary on the Triangle Complex

Each row represents one level of the bipartition; Color represents the sign info

# The *Fine-to-Coarse* GHWT Dictionary on the Triangle Complex

Color represents the sign info; the red boxes correspond to the *2-Haar Basis*

# Approximation of the Coauthorship Complex

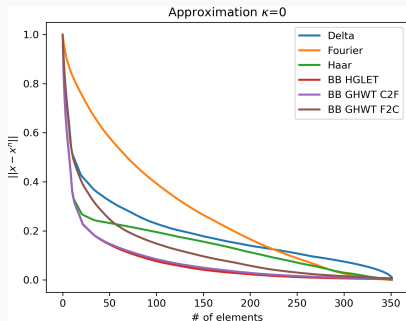

From Elbi et al. 2022

- The Coauthorship Complex (CC) [Patania et al. (2017); Elbi et al. (2022)] can be created by linking papers, authors, and coauthors from the Semantic Scholar Open Research Corpus.
- Each node represents an author, whose value is the total citation number of publications of that author.
- *Each  $k$ -simplex represents the coauthorship among  $(k + 1)$  authors*, whose value is the total citation number of the publications coauthored by these  $(k + 1)$  coauthors.

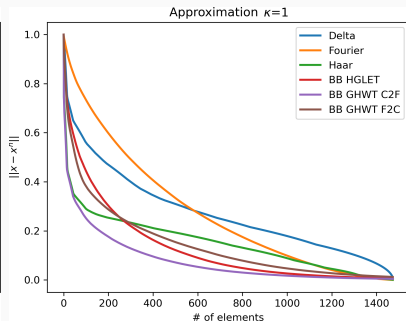

$k$	0	1	2	3	4	5
# of elements	352	1474	3285	5019	5559	4547

The size of  $k$ -simplices in the CC for  $k = 0, 1, \dots, 5$

# Approximation of Coauthorship Complexes: $k = 0, 1$

$k = 0$

$k = 1$

The behavior of these plots may be explained by the following

## Theorem (Sharon-Shkolnisky (2015))

For a fixed orthonormal basis  $\{\phi_l\}_{l=0}^{n-1}$  and a parameter  $0 < \tau < 2$ ,

$$\|f - P_m f\|_2 \leq \frac{|f|_\tau}{m^\alpha}, \quad \text{where } |f|_\tau := \left( \sum_{l=0}^{n-1} |\langle f, \phi_l \rangle|^\tau \right)^{1/\tau} \text{ and } \alpha = \frac{1}{\tau} - \frac{1}{2}.$$

# Approximation of Coauthorship Complexes: $k = 2 : 5$

$k = 2$

$k = 3$

$k = 4$

$k = 5$

# Building Scattering Networks on $k$ -Simplices

- Want to generalize the *scattering transform* of Mallat to the simplicial complex setting because we want to extract *robust* features from data recorded on simplicial complexes.
- Gao, Wolf, and Hirn (2021) proposed the *Geometric Scattering* for graphs (0-simplices) using the *diffusion wavelets* of Coifman and Maggioni (2006).
- We propose to *use our  $k$ -HGLET and  $k$ -GHWT dictionaries to build such scattering transforms/networks.*
- Let the  $k$ -HGLET or  $k$ -GHWT dictionary vectors be arranged as  $\Phi^J := \{\Phi^j\}_{j=0}^J$  where each  $\Phi^j$  is an ONB at scale (or level)  $j$  with  $j = 0$  being the finest scale basis, composed of delta functions.
- In general, we have  $j_{\max} \approx 1 + \log_2 n$  different levels but in practice, the features extracted by large  $j$  values are not very descriptive, so we typically use the first  $J (< j_{\max})$  levels.

# Building Scattering Networks on $k$ -Simplices ...

- Let  $\mathbf{f} \in \mathbb{R}^n$  be a signal defined on  $C_k$ .
- We propose to compute the  $q$ th moment of the 0th and 1st scattering coefficients:

$$S^0(q) := \sum_{i=1}^n \mathbf{f}[i]^q, \quad S^1(q, j) := \sum_{i=1}^n |\Phi^j \mathbf{f}[i]|^q, \quad 0 \leq j \leq J; 1 \leq q \leq Q, \quad (1)$$

and the 2nd-order scattering coefficients:

$$S^2(q, j, j') := \sum_{i=1}^n |\Phi^{j'} |\Phi^j \mathbf{f}[i]|^q, \quad j = 0 \leq j < j' \leq J, 1 \leq q \leq Q. \quad (2)$$

- And higher-order scattering coefficients can be computed similarly:

$$S^m(q, j^{(1)}, \dots, j^{(m)}) := \sum_{i=1}^n |\Phi^{j^{(m)}} |\Phi^{j^{(m-1)}} \dots |\Phi^{j^{(1)}} \mathbf{f}[i]|^q, \quad (3)$$

where  $\mathbf{j} = 0 \leq j^{(1)} < \dots < j^{(m)} \leq J$ .

- However, to reduce the computational cost, we typically use  $m \leq 3$ .

## Building Scattering Networks on $k$ -Simplices ...

- Gathering all of the moments  $\leq Q$  and of orders  $\leq M$  leads to a total of  $Q \sum_{m=0}^M \binom{J+1}{m}$  features for a given signal; e.g. for  $(J, M, Q) = (5, 3, 4)$ , it's just 178 features/signal.
- The summations from  $i = 1$  to  $i = n$  in (1)–(3) can be viewed as *global pooling* operations.
- In situations where node permutation invariance is not required, we can omit these sums, which is *no pooling*. As a result, we are left with  $nQ \sum_{m=0}^M \binom{J+1}{m}$  features for each signal.
- Finally, we sum the coefficients over each partition (i.e., region) at level  $j$  and keep those local sums as feature vectors instead of not summing at all or summing all the regions of level  $j$  in (1)–(3), which can be viewed as *local pooling* operations.
- We call our scattering networks as *Multiscale Hodge Scattering Networks* (MHSNs).

# Classification of Science News Articles

- Apply our MHSNs to *article category classification* using the *Science News* database.
- After some preprocessing, the Science News dataset contains 1042 scientific news articles classified into eight fields: *Anthropology; Astronomy; Behavioral Sciences; Earth Sciences; Life Sciences; Math/CS; Medicine; Physics.*
- Each article is tagged with *keywords* from a pool of 1133 words. In this database, each article contains 2 ~ 5 keywords (with/without counting their frequency of occurrence).
- We determine a simplicial complex from these keywords by 1) computing their **word2vec** embeddings based on Google's publicly available pre-trained model; and 2) generate a symmetric  $K$ -nearest neighbor graph of the embedded words and then generate  $k$ -simplices of the graph.
- *A  $k$ -simplex corresponds to a combination of  $(k + 1)$  words.*

## Generation of Simplicial Signals on $C_k$

Next, we define representations of each article as a signal on each  $C_k$  as follows.

- First, for  $k = 0$  (i.e., a node-valued signal), we define the signal  $f_0$  to be one on the nodes representing their keywords and zero elsewhere.
- For  $k \geq 1$  we define the signal  $f_k$  to be the simplex-wise average of the  $f_0$  signal.

$$f_0[i] = \begin{cases} 1 & \text{if keyword } i \text{ occurs} \\ 0 & \text{Otherwise} \end{cases}; \quad f_k[i] = \frac{1}{k+1} \sum_{\substack{l \in V(\sigma_i) \\ \sigma_i \in C_k}} f_0[l], \quad (4)$$

where  $V(\sigma_i)$  represents the set of nodes forming the  $i$ th simplex  $\sigma_i \in C_k$ .

# Classification Results

- For each  $k$ , we did 10-fold cross validation: randomly split these 1042 signals into 10 groups; each group was used as a test set while the other 9 groups were used as a training set; and repeated this 10 times.
- Used  $\ell^2$ -regularized logistic regression provided by `scikit-learn`
- The parameters in the MHSNs were set as  $(J, M, Q) = (5, 3, 4)$ .
- The task is not necessarily easy: consider the article on ‘star-nosed moles’ titled “Snouts: A star is born in a very odd way,” which belongs to *Life Science*, not *Astronomy*!

# Graph/Simplicial Complex Classification

- Can we predict a label or a category of a social or chemical graph based on a training set of similar graphs with different configurations (e.g., different number of nodes, edges, etc.)?
- Due to a great variety of graph sizes, we only use the *global pooling* version of our MHSNs.
- Use a Support Vector Machine with a radial basis function kernel for classifying the features that MHSNs generated.
- Focus on the nodes  $k = 0$  and the edges  $k = 1$ .
- For  $k = 0$ , the input signal of a given graph is its *eccentricity* and *clustering coefficient* of each vertex as used in the *Geometric Scattering* of Gao et al.
- For  $k = 1$ , the input signal of a given graph is the *number of nonzero off-diagonal components of the Hodge Laplacians* ( $\approx$  “degree” of each edge) and the *average vertex degree of the head and tail nodes of each edge*.

UGT := Universal Graph Transformers [Nguyen et al. (2022)];

DGCNN := Dynamic Graph CNN [Wang et al. (2018)];

GAT := Graph Attention Networks [Veličković et al. (2017)];

GFN := Graph Feature Networks [Chen et al. (2019)]

⇒ Our MHSNs achieved quite competitive results *with only a small fraction of the learnable parameters* as the next table indicates!

## Classification Results ...

Graph	Hodge Scattering + SVM		UGT		GFN	
	Accuracy	# Param	Accuracy	# Param	Accuracy	# Param
Collab	80.39	256	77.84	866,746	81.50	68,754

# Learning Molecular Dynamics

- Want to *predict potential energy surface of a molecule* given some registrations of the molecule and its energies
- The *Revised Molecular Dynamics 17* (rMD17) dataset [Bowman et al., 2022)] contains **100,000** structures and associated energies of various molecules based on molecular dynamics simulation
- Used *Aspirin* (21 atoms =  $C_9H_8O_4$ ) and *Paracetamol* (20 atoms =  $C_8H_9NO_2$ ) as molecules
- Selected five sets of **1,000** snapshots of the structures/energies per molecule
- In each of five sets, **800** snapshots are used for training and **200** for test
- *Support vector regression* (SVR) with Gaussian radial basis functions is used as a regression method on the computed MHSN features

**Summary & Future Plan**

References

# Summary

---

- Developed the *multiscale higher-order graph signal basis dictionaries for simplicial complexes*: the *k-HGLET dictionary* and the *k-GHWT dictionary* for signals sampled on edges, faces, etc.
- Proposed the *multiscale Hodge scattering networks* based on these dictionaries
- Demonstrated their competitiveness in: classification of signals on  $k$ -simplices (the Science News article categorization); classification of graphs (of different sizes, different topology, etc.); and learning potential energy surface of molecules
- These dictionary coefficients and scattering coefficients should provide *explicit interpretation* (e.g., scale, frequency, position, etc.) of their importance for a given task.

# Future Plan

- Develop *tools to visualize and interpret important basis vectors* for signals on simplicial complexes including *graph embedding methods*
- Develop the simplicial complex version of the *Natural Graph Wavelet Packets* (Cloninger-Li-Saito, 2021) where bipartitioning is done on the *dual domain* where the nodes are the global eigenvectors
- Implement *Local Discriminant Basis (LDB)*, *Local Regression Basis (LRB)*, etc. [Saito et al. (1995; 1997; 2002; ...)], for simplicial signals
- Reduce computational complexity of  $O(N^3)$  for the  $k$ -HGLET:
  - ▶ For certain problems, one may not need all the GL eigenvectors, in particular, those corresponding to the large eigenvalues.
  - ▶ Consider *integral operators* (e.g., *Green's functions*) on graphs, and utilize the *Fast Multipole Method* [Saito (2008); Xue (2007)]
- Truly generalize the *Local Cosine Transform (LCT)* for the graph setting. H. Li (2021) constructed the node version of the *smooth orthogonal projectors involving orthogonal folding and unfolding operators* and the graph basis dictionaries, but we need proper *boundary conditions* at the partition locations.
