## ***Lemma:***

Let  $S_1$  and  $S_2$  be two sets of points with the same cardinality  $N$  and let  $C$  be a real-valued cost matrix between  $S_1$  and  $S_2$ .

Let  $G$  be an assignment matrix between  $S_1$  and  $S_2$  that satisfies the constraints on row sum and column sum, namely  $G$  is a permutation matrix, and let  $U(G, C)$  be the total cost associated with  $G$ .

Let  $\mathbf{a}$  and  $\mathbf{b}$  be any two real-valued vectors of size  $N$ , and let  $D_{\mathbf{a}, \mathbf{b}}$  be the matrix defined as

$$D_{\mathbf{a}, \mathbf{b}}(k, l) = C(k, l) + a(k) + b(l)$$

Then,

$$U(G, D_{\mathbf{a}, \mathbf{b}}) = U(G, C) + \sum_k a(k) + \sum_l b(l)$$

# Hungarian algorithm

## ***Lemma:***

Let  $S_1$  and  $S_2$  be two sets of points with the same cardinality  $N$  and let  $C$  be a real-valued cost matrix between  $S_1$  and  $S_2$ .

Let  $G$  be an assignment matrix between  $S_1$  and  $S_2$  that satisfies the constraints on row sum and column sum, namely  $G$  is a permutation matrix, and let  $U(G, C)$  be the total cost associated with  $G$ .

Let  $\mathbf{a}$  and  $\mathbf{b}$  be any two real-valued vectors of size  $N$ , and let  $D_{\mathbf{a}, \mathbf{b}}$  be the matrix defined as

$$D_{\mathbf{a}, \mathbf{b}}(k, l) = C(k, l) + a(k) + b(l)$$

Then,

$$U(G, D_{\mathbf{a}, \mathbf{b}}) = U(G, C) + \sum_k a(k) + \sum_l b(l)$$

*Shift row values / column values to get a “simpler” cost matrix with one 0 per row and per column*

# Hungarian algorithm

*1) Rows:*

$$\sum_l G(k, l) = 1 \quad \forall k$$

$$\sum_k G(k, l) = 1 \quad \forall l$$

# Finite temperature assignment

Using Fourier, we can represent a delta function as an integral of an exponential,

$$\delta(x) = \frac{1}{2\pi} \int e^{-ixt} dt$$

$$Z_\beta(S_1, S_2) = \sum_{G(k,l) \in \{0,1\}} e^{-\beta \sum_{kl} C(k,l)G(k,l)} \times \\ \int_{-\infty}^{+\infty} \prod_k d\lambda(k) e^{-\beta \sum_{k,l} \lambda(k)G(k,l) + \beta \sum_k \lambda(k)} \times \int_{-\infty}^{+\infty} \prod_l d\mu(l) e^{-\beta \sum_{k,l} \mu(l)G(k,l) + \beta \sum_l \mu(l)}$$

$$Z_\beta(S_1, S_2) = \int_{-\infty}^{+\infty} \prod_k d\lambda(k) \int_{-\infty}^{+\infty} \prod_l d\mu(l) e^{\beta \left( \sum_k \lambda(k) + \sum_l \mu(l) \right)} \\ \sum_{G(k,l) \in \{0,1\}} e^{-\beta G(k,l)(C(k,l) + \lambda(k) + \mu(l))}$$

# Finite temperature assignment

$$Z_{\beta}(S_1, S_2) = \int_{-\infty}^{+\infty} \prod_k d\lambda(k) \int_{-\infty}^{+\infty} \prod_l d\mu(l) e^{\beta \left( \sum_k \lambda(k) + \sum_l \mu(l) \right)} \sum_{G(k,l) \in \{0,1\}} e^{-\beta G(k,l)(C(k,l) + \lambda(k) + \mu(l))}$$

$$Z_{\beta}(S_1, S_2) = \int_{-\infty}^{+\infty} \prod_k d\lambda(k) \int_{-\infty}^{+\infty} \prod_l d\mu(l) e^{\beta \left( \sum_k \lambda(k) + \sum_l \mu(l) \right) + \sum_{k,l} \ln(1 + e^{-\beta(C(k,l) + \lambda(k) + \mu(l))})}$$

# Finite temperature assignment

$$Z_{\beta}(S_1, S_2) = \int_{G \in \mathcal{G}} e^{-\beta U(G)}$$

$$Z_{\beta}(S_1, S_2) = \int_{-\infty}^{+\infty} \prod_k d\lambda(k) \int_{-\infty}^{+\infty} \prod_l d\mu(l) e^{-\beta F_{\beta}(\lambda, \mu)}$$

where

$$F_{\beta}(\lambda, \mu) = - \left( \sum_k \lambda(k) + \sum_l \mu_l \right) - \frac{1}{\beta} \sum_{kl} \ln \left( 1 + e^{-\beta(C(k, l) + \lambda(k) + \mu(l))} \right)$$

# Finite temperature assignment

$$F_{\beta}(\lambda, \mu) = - \left( \sum_k \lambda(k) + \sum_l \mu_l \right) - \frac{1}{\beta} \sum_{kl} \ln \left( 1 + e^{-\beta(C(k,l) + \lambda(k) + \mu(l))} \right)$$

## Theorems:

- 1) The Hessian of the effective free energy  $F_{\beta}(\lambda, \mu)$  is negative semi-definite with  $2N - 1$  negative eigenvalues and one zero eigenvalue.
- 2) The eigenvector corresponding to the zero eigenvalue is  $(1, \dots, 1, -1, \dots, -1)$  (with  $N$  1s, and  $N$  -1s)
- 3) Setting one of the parameters  $\lambda(k)$  or  $\mu(l)$  as zero, the free energy function on this restricted parameter space is strictly concave.

$$G^{MF} \xrightarrow{\beta \rightarrow +\infty} ?$$

# Finite temperature assignment

$$U_{\beta}^{MF} = \sum_k \sum_l C(k, l) G^{MF}(k, l) \xrightarrow{\beta \rightarrow +\infty} U^*$$

$$G^{MF} \xrightarrow{\beta \rightarrow +\infty} ?$$

## Theorem:

If the assignment problem has a unique solution among all permutations, then there are no non integer solutions

# Finite temperature assignment

$$U_{\beta}^{MF} = \sum_k \sum_l C(k, l) G^{MF}(k, l) \xrightarrow{\beta \rightarrow +\infty} U^*$$

$$G^{MF} \xrightarrow{\beta \rightarrow +\infty} G^*$$

## Theorem:

If the assignment problem has a unique solution among all permutations, then there are no non integer solutions

# Finite temperature assignment

**Hypothesis: there is a unique solution**

## Theorem:

Let  $\Delta$  be the difference in energy between the best solution and the second best solution. Then:

$$\max_{k,l} \left| G_{\beta}^{MF}(k, l) - G^*(k, l) \right| \leq \frac{A(N)}{\beta \Delta}$$

Furthermore, rounding off each of the entries of  $G_{\beta}^{MF}$  to the nearest integer yields the permutation matrix  $G^*$  whenever

$$\beta > \frac{2A(N)}{\Delta}$$

$$A(N) = N (N \log(N) - (N - 1) \log(N - 1))$$

# Finite temperature assignment

**Hypothesis: there is a unique solution**

**Theorem:**

Let us assume that at an inverse temperature  $\beta$  the current solution matrix  $G_\beta^{MF}$  is row dominant. Then rounding off each of the entries of  $G_\beta^{MF}$  to the nearest integer yields the permutation matrix  $G^*$

# Finite temperature assignment

**Hypothesis: there is a unique solution**

# Finite temperature assignment

*Hypothesis:*

*the converged solution has some elements strictly in  $(0,1)$*

| 0     | 0 | 1 | 0     | 0 |
| 0.6+e | 0 | 0 | 0.4-e | 0 |
| 0     | 0 | 0 | 0     | 1 |

$$U = 0.4C(2,1) + 0.6C(2,4) + 0.6C(4,1) + 0.4C(4,4) + E - e(C(2,1) - C(2,4) + C(4,4) - C(4,1))$$

# Finite temperature assignment

*Hypothesis:*

*the converged solution has elements strictly in (0,1)*

|       |   |   |       |   |
|-------|---|---|-------|---|
| 0     | 1 | 0 | 0     | 0 |
| 0.4-e | 0 | 0 | 0.6+e | 0 |
| 0     | 0 | 1 | 0     | 0 |
| 0.6+e | 0 | 0 | 0.4-e | 0 |
| 0     | 0 | 0 | 0     | 1 |

Necessarily:

$$A) C(2,1) - C(2,4) + C(4,4) - C(4,1) = 0$$

B) Setting  $e = 0.4$  leads to an integer solution

$$U = U^* - e(C(2,1) - C(2,4) + C(4,4) - C(4,1))$$

# Finite temperature assignment

*Hypothesis:*

*the converged solution has elements strictly in (0,1)*

**Theorem :** (*Gartner and Matousek, 2006*)

If the relaxed assignment problem has at least one feasible solution, then it has at least one integral optimal solution. This solution is an optimal solution for the corresponding integer assignment program.

**Property:**

If the relaxed assignment problem has an optimum solution that contains fractional elements, then there exists (at least) one cycle  $A = \{(a_1, b_1), (a_2, b_2), \dots, (a_{2M}, b_{2M})\}$  in the cost matrix  $C$  for which  $\Gamma = \sum_{i=1}^{2M} (-1)^i C(a_i, b_i) = 0$ .

# Finite temperature assignment

*Hypothesis:*

*the converged solution has elements strictly in (0,1)*

## Theorem

Let  $\Delta$  be the difference in total cost between the optimal solution and the second best solution. Then, adding random uniform noise with support  $(0,\alpha]$  to each value of  $C$  and solving the assignment problem on this perturbed matrix will generate one integer solution that is also solution to the unperturbed assignment problem with probability 1, whenever

$$\alpha < \frac{\Delta}{2N}$$

If all the entries of the cost matrix  $C$  are scaled to be integers, then  $\Delta \geq 1$  and it suffices to have

$$\alpha < \frac{1}{2N}$$
