An Instability of the Standard Model Creates the Anomalous Acceleration Without Dark Energy

August 28, 2015

Joel Smoller1 Blake Temple2 Zeke Vogler2

1. Abstract

We introduce a new asymptotic ansatz for spherical perturbations of the Standard Model of Cosmology (SM) which applies during the $p = 0$ epoch, and prove that these perturbations trigger an instability in the SM on the scale of the supernova data. The instability creates a large, under-dense region of accelerated uniform expansion which introduces precisely the same range of corrections to redshift vs luminosity as are produced by the cosmological constant in the theory of Dark Energy. A universal behavior is exhibited because all spherically symmetric solutions that are smooth at $r = 0$ in Standard Schwarzschild Coordinates (SSC) are characterized by the two dimensional phase portrait of the instability, and according to this phase portrait, all sufficiently small under-dense perturbations evolve to a single stable rest-point. The instability is triggered by the one parameter family of self-similar waves which the authors previously proposed as possible local time-asymptotic wave patterns for perturbations of the SM at the end of the radiation epoch. A numerical simulation determines a unique wave in the family that accounts for the same Hubble constant and quadratic correction to redshift vs luminosity as in a universe with seventy percent Dark Energy, and the third order correction distinguishes the two theories.

2. Introduction

In this announcement we accomplish the program set out by the first two authors in [25, 20, 21], to evolve a one parameter family of

GR simple-waves\footnote{By \textit{simple-wave} we mean a perturbation of the Friedmann space-time on which the Einstein equations reduce to ODE’s, c.f. \cite{6}.} which the authors identified as canonical perturbations of the Standard Model of cosmology (SM)\footnote{Assuming the so-called cosmological Principle, that the universe is uniform on the largest scale, the evolution of the universe on that scale is described by a Friedmann spacetime, \cite{27}, which is determined by the equation of state in each epoch. In this paper we let SM denote the approximation to the Standard Model of cosmology without Dark Energy given by the critical $k = 0$ Friedmann universe with equation of state $p = \frac{\rho}{3} \rho$ during the radiation epoch, and $p = 0$ thereafter, (c.f. the $\Lambda CDM$ model with $\Lambda = 0$, \cite{13}).} during the radiation epoch of the Big Bang, up through the $p = 0$ epoch to present time, with the purpose of investigating a possible connection with the observed anomalous acceleration of the galaxies, \cite{20, 13}. Our analysis is based on the discovery of a closed ansatz for perturbations of the SM during the $p = 0$ epoch of the Big Bang which triggers instabilities that create unexpectedly large regions of accelerated uniform expansion within Einstein’s original theory without the cosmological constant. We prove that these accelerated regions introduce \textit{precisely} the same range of corrections to redshift vs luminosity as are produced by the cosmological constant in the theory of Dark Energy. A universal behavior is exhibited because all sufficiently small perturbations tend time asymptotically to a single stable rest point where the spacetime is Minkowski. Based on this, we accomplish our initial program by proving that these perturbations are consistent with, and the instability is triggered by, the one parameter family of self-similar waves proposed by the authors in \cite{20} as possible time-asymptotic wave patterns for perturbations of the SM at the end of the radiation epoch. By numerical simulation we identify a unique wave in the family that accounts for the same values of the Hubble constant and quadratic correction to redshift vs luminosity as are implied by the theory of Dark Energy with $\Omega_\Lambda \approx .7$. A numerical simulation of the third order correction associated with that unique wave establishes a testable prediction that distinguishes this theory from the theory of Dark Energy, (see Figure 1 below). The result is an alternative, testable mathematical explanation for the anomalous acceleration of the galaxies that does not invoke Dark Energy, and is based upon the identification of a new instability of the SM on the scale of the supernova data, and a family of simple wave perturbations that trigger it.

Most of the expansion of the universe before the pressure drops to $p \approx 0$, is governed by the radiation epoch, a period in which the evolution is described by the equations of pure radiation. These equations...
take the form of the relativistic $p$-system of shock wave theory, and for such highly nonlinear equations, one expects complicated solutions to become simpler. A rigorous theory in one space dimension shows that solutions of the fluid equations decay to a concatenation of simple waves, solutions along which the equations reduce to ODE’s, [12, 6, 21]. Based on this, together with the fact that large fluctuations from the radiation epoch (like the baryonic acoustic oscillations) are typically spherical, [13], the authors began the program in [25] by looking for a family of spherically symmetric solutions that perturb the SM during the radiation epoch when the equation of state $p = \frac{c^2}{3} \rho$ holds, and on which the Einstein equations reduce to ODE’s. In [20, 21], we identified a unique family of such solutions which we refer to as $a$-waves, parameterized by the so called acceleration parameter $a > 0$, normalized so that $a = 1$ is the SM. This family of waves was first discovered from a different point of view in the profoundly interesting paper [1] by Cahill and Taub, and is the only known family of solutions which both (1) perturb Friedmann spacetimes, and (2) reduce the Einstein equations to ODEs, [1, 21, 2]. Since when $p = 0$, under-densities relative to the SM are a natural mechanism for creating anomalous accelerations, (less matter present to slow the expansion implies a larger expansion rate, [13]), we restrict to the perturbations $a < 1$ which induce under-densities relative to the SM, [20, 21]. This requires that we abandon the cosmological Principle on the scale of these perturbations.

Thus our starting hypothesis is that the anomalous acceleration of the galaxies is due to a local under-density relative to the SM, on the scale of the supernova data [4], created by a perturbation that has decayed (locally near the center) to an $a$-wave, $a < 1$, by the end of the radiation epoch. We prove the following: (i) The SM is unstable to perturbation by $a$-waves; (ii) A small under-density created by an $a$-wave at the end of radiation, triggers the formation of a large region of accelerated expansion which extends further and further outward from the center, becoming more flat and more uniform, as time evolves; (iii)
Neglecting errors in the measurable quantities of fourth order in fractional distance to the Hubble Length, (c.f. footnote 8 below.), this extended region moving outward from the center evolves according to an autonomous system of two ODE’s, and is described by a solution trajectory that starts near a classic unstable saddle rest point corresponding to the SM at the end of radiation, and evolves to a nearby stable rest point $M$ where the metric is Minkowski. (iv) We show (in the Appendix) that all spherically symmetric solutions that are smooth in SSC coordinates and admit Taylor expansions in the SSC radial variable at the center $r = 0$, are gauge equivalent to solutions characterized by the two dimensional phase portrait of the leading order asymptotic equations in which SM appears as an unstable saddle rest point $SM$, and all solutions within a global domain of attraction evolve to the rest point $M$. During the evolution from $SM$ to $M$, the quadratic correction to redshift vs luminosity (as measured near the center) assumes precisely the same range of values as Dark Energy theory. That is, letting

$$H d_\ell = z + Q z^2 + C z^3 + O(z^4)$$  \hspace{1cm} (2.1)$$

denote the relation between redshift factor $z$ and luminosity distance $d_\ell$ at a given value of the Hubble constant $H$ as measured at the center$^5$, the value of the quadratic correction $Q$ increases from the $SM$ value $Q = 0.25$ at the end of radiation, to the value $Q = 0.5$ as $t \to \infty$. This is precisely the same range of values $Q$ takes on in Dark Energy theory as the fraction $\Omega_\Lambda$ of Dark Energy to classical energy increases from its value of $\Omega_\Lambda \approx 0$ at the end of radiation, to $\Omega_\Lambda = 1$ as $t \to \infty$. This holds for any $a < 1$ near $a = 1$, and for any value of the cosmological constant $\Lambda > 0$, assuming only that $a$ and $\Lambda$ both induce a negligibly small correction to the SM value $Q = 0.25$ at the end of radiation.$^6$

These results are recorded in the following theorem. Here we let present time in a given model denote the time at which the Hubble constant $H$ (as defined in (2.1)) reaches its present measured value $H = H_0$, this time being different in different models.

$^5$For the FRW spacetime, $Q$ is determined by the value of the so-called deceleration parameter $q$, and $C$ is determined by the jerk, c.f., [13].

$^6$We qualify with this latter assumption only because, in Dark Energy theory, the value of $\Omega_\Lambda$ is small but not exactly equal to zero at the end of radiation; and in the wave theory, the value of $Q$ jumps down slightly below $Q = 0.25$ at the end of radiation before it increases to $Q = 0.5$ from that value as $t \to \infty$. 

Theorem 1. Let \( t = t_0 \) denote present time in the wave model and \( t = t_{DE} \) present time in the Dark Energy\(^7\) model. Then there exists a unique value of the acceleration parameter \( a = 0.99999959 \approx 1 - 4.3 \times 10^{-7} \) corresponding to an under-density relative to the SM at the end of radiation, such that the subsequent \( p = 0 \) evolution starting from this initial data evolves to time \( t = t_0 \) with \( H = H_0 \) and \( Q = 0.425 \), in agreement with the values of \( H \) and \( Q \) at \( t = t_{DE} \) in the Dark Energy model. The cubic correction at \( t = t_0 \) in the wave theory is then \( C = \frac{0.359}{10^{-6}} \), while Dark Energy theory gives \( C = \frac{-0.180}{10^{-7}} \) at \( t = t_{DE} \).

We emphasize that \( t_0, Q \) and \( C \) in the wave model, are determined by \( a \) alone. Indeed, the initial data at the end of radiation, which determines the \( p = 0 \) evolution, depends, at the start, on two parameters: the acceleration parameter \( a \) of the self-similar waves, and the initial temperature \( T_* \) at which the pressure is assumed to drop to zero. But our numerics show that the dependence on the starting temperature is negligible for \( T_* \) in the range \( 3000^\circ K \leq T_* \leq 9000^\circ K \), (the range assumed in cosmology, [13]). Thus for the temperatures appropriate for cosmology, \( t_0, Q \) and \( C \) are determined by \( a \) alone.

A measure of the severity of the instability created by the \( a = \) perturbation of the SM , is quantified by the numerical simulation. For example, comparing the initial density \( \rho_{\text{wave}} \) for \( a = \) at the center of the wave, to the corresponding initial density \( \rho_{\text{sm}} \) in the SM at the end of radiation \( t = t_* \), gives \( \frac{\rho_{\text{wave}}}{\rho_{\text{sm}}} \approx 1 - (7.45) \times 10^{-6} \approx 1 \). During the \( p = 0 \) evolution, this ratio evolves to a seven-fold under-density in the wave model relative to the SM by present time, i.e., \( \frac{\rho_{\text{wave}}}{\rho_{\text{sm}}} = 0.146 \) at \( t = t_0 \).

Note that in principle adding acceleration to a model should increase the expansion rate \( \dot{H} \) and consequently the age of the universe, because it then takes longer for the Hubble constant \( H \) to decrease to its present small value \( H_0 \).

Our wave theory is based on the self-similarity variable \( \xi = r/ct < 1 \), which is a measure of the fractional distance from the center \( \xi = 0 \) to the Hubble length at time \( t \) when \( \xi << 1 \).\(^8\) We show below (c.f.

---

\(^7\)By the Dark Energy model we refer to the critical \( k = 0 \) Friedmann universe with cosmological constant, taking the present value \( \Omega_\Lambda = 0.7 \) as the best fit to the supernova data among the two parameters \((k, \Lambda)\), [15, 16].

\(^8\)That is, a natural definition of the Hubble length in the perturbed space-times is \( 1/ct \) for \( t \)-time since the Big Bang as measured by the observer positioned at \( r = 0 \). So using that \( r \) well approximates arc length radial distance from the center at fixed time when \( \xi << 1 \), we interpret \( r/ct \) as measuring the “fractional distance to the Hubble length”. This is just a measure, and doesn’t have to be exact
Section 3.3), that if we neglect errors $O(\xi^4)$, and then further neglect small errors between the wave metric and the Minkowski metric (which tend to zero, at that order, with approach to the stable rest point, c.f. (iii) above), and also neglect errors due to relativistic corrections in the velocities of the fluid relative to the center (where the velocity is zero), the resulting spacetime is, like a Friedmann spacetime, independent of the choice of center. Thus the central region of approximate uniform density at present time $t = t_0$ in the wave model extends out from the center $r = 0$ at $t = 0$ in SSC, to radial values $r$ small enough so that the fractional distance to the Hubble length $\xi = r/c t_0$ satisfies $\xi^4 << 1$.

The cubic correction $C$ to redshift vs luminosity is a verifiable prediction of the wave theory which distinguishes it from Dark Energy theory. In particular, $C > 0$ in the wave model and $C < 0$ in the Dark Energy model implies that the cubic correction increases the right hand side of (2.1), (i.e., increases the discrepancy between the observed redshifts and the predictions of the SM ) far from the center in the wave theory, while it decreases the right hand side of (2.1) far from the center in the Dark Energy theory. Now the anomalous acceleration was originally derived from a collection of data points, and the $\Omega_A \approx .7$ critical FRW spacetime is obtained as the best fit to Friedmann spacetimes among the parameters $(k, \Lambda)$. We understand that the current data is sufficient to provide a value for $Q$, but not $C$, [10]. Presently it is not clear to the authors whether or not there are indications in the data that could distinguish $C < 0$ from $C > 0$.

Finally, we remark that the problems we posed and solved in this paper resulted from a self-contained line of reasoning stemming from questions that naturally arose from authors’ earlier investigations on incorporating a shock wave into the SM of cosmology, [19, 20, 21]. Other interesting attempts to model the anomalous acceleration by under-density theories based on solutions in Lemaitre-Tolman-Bondi (LTB) coordinates can be found in [4, 5], and references [37]-[65] of [26], including [28]-[36] listed below. In the Appendix below we discuss the relationship between LTB solutions and the SSC solutions we introduce here.

3. Presentation of Results

We summarize the sections of our forthcoming paper which brings our identified one parameter family of GR $a$-waves up through the $p = 0$ epoch of the Big Bang to present time. We quantify the quadratic because “fractional distance to the Hubble length” only has an exact meaning in the Friedmann spacetimes, [27, 18, 21].
Figure 1. Phase Portrait for Central Region

corrections $Q$ implied in (2.1) by these perturbations to SM near the center, and compare the results with Dark Energy theory.

We begin by recalling that $a$-waves form a 1-parameter family of spherically symmetric solutions of the Einstein equations $G = \kappa T$ that depend only on the self-similarity variable $\xi = r/t$, and exist when $p = \frac{\rho}{3}$. They reduce to the critical SM Friedmann spacetime for pure radiation when $a = 1$. In contrast, when $p = 0$, only the SM $p = 0$, $k = 0$ Friedmann spacetime can be expressed in this self-similar form. Our expansion of the time independent self-similar waves during the radiation epoch in powers of $\xi$ calculated in [21] has led us to the discovery of a new time dependent asymptotic ansatz for corrections to the standard model, that depend on $(t, \xi)$, and close at order $\xi^4$ under the $p = 0$ evolution. This ansatz is sufficiently general to incorporate initial data from the self-similar waves at the end of radiation, and hence the evolution of these waves into time dependent solutions during the $p = 0$ epoch. In this paper we deduce the evolution of the corrections induced by $a$-waves at the end of radiation from the phase portrait of these asymptotic equations. In fact, our main result, that an instability in the SM can create the anomalous acceleration of the galaxies without Dark Energy, applies not just to perturbations by $a$-waves, but to any perturbation consistent with our asymptotic ansatz at the end of radiation, so long as the perturbation lies within the domain of attraction of the stable rest point to which the perturbation $a = a$ evolves.
In Sections 3.1-3.3 we derive an alternative formulation of the $p = 0$ Einstein equations in spherical symmetry, introduce our new asymptotic ansatz for corrections to the SM, use the exact equations to derive equations for the corrections, and use these to characterize the instability. In Section 3.4 we derive the correct redshift vs luminosity relation for the SM including the corrections. In Section 3.5 we introduce a gauge transformation that converts the $a$-waves at the end of radiation into initial data that is consistent with our ansatz. In Section 3.6 we present our numerics that identifies the unique $a$-wave $a = a$ in the family that meets the conditions $H = H_0$ and $Q = .425$ at $t = t_0$, and explain our predicted cubic correction $C = 0.359$. In Section 3.7 we discuss the uniform space-time created at the center of the perturbation. Concluding remarks are given in Section 4. Details are omitted in this announcement. We use the convention $c = 1$ when convenient.

3.1. The $p = 0$ Einstein Equations in Coordinates Aligned with the Physics. In this section we introduce a new formulation of the $p = 0$ Einstein equations that describe outwardly expanding spherically symmetric solutions. We do not employ co-moving coordinates, [4], but rather use $\xi$ as a spacelike variable because it is better aligned with the physics. That is, our derivation starts with metrics in Standard Schwarzschild Coordinates (SSC), where the metric takes the canonical form,

$$ds^2 = -B(t,r)dt^2 + \frac{1}{A(t,r)} dr^2 + r^2 d\Omega^2, \quad (3.2)$$

but our subsequent analysis is done in $(t, \xi)$ coordinates, where $\xi = r/t$. Our starting point is the observation that the SSC metric form is invariant under transformations of $t$, and there exists a time coordinate in which SM is self-similar in the sense that the metric components $A, B$, the velocity $v$ and $\rho r^2$ are functions of $\xi$ alone. This self-similar form exists, but is different for $p = \frac{c^2}{3}\rho$ and $p = 0$, [2, 22]. Taking $p = 0$, letting $v$ denote the SSC velocity and $\rho$ the co-moving energy density, and eliminating all unknowns in terms of $v$ and the Minkowski energy density $T_{00}^M = \frac{\rho}{1-(\xi)^2}$, (c.f. [8]), the locally inertial formulation of the Einstein equations $G = \kappa T$ introduced in [8] reduce to
(\kappa T_M^{00} r^2)_t + \left\{ \sqrt{AB} \left( \kappa T_M^{00} r^2 \right) \right\}_r = -2\sqrt{AB} \left( \kappa T_M^{00} r^2 \right),

\left( \frac{v}{r} \right)_t + r\sqrt{AB} \left( \frac{v}{r} \right)_r = -\sqrt{AB} \left\{ \left( \frac{v}{r} \right)^2 + \frac{1-A}{2A r^2} \left( 1 - r^2 \left( \frac{v}{r} \right)^2 \right) \right\},

r_{A'} = \left( \frac{1}{4} - 1 \right) - \frac{1}{4} \kappa T_M^{00} r^2,

r_{B'} = \left( \frac{1}{4} - 1 \right) + \frac{1}{4} \left( \frac{v}{r} \right)^2 \kappa T_M^{00} r^2,

where prime denotes d/dr. Note that the 1/r singularity is present in the equations because incoming waves can amplify without bound. We resolve this for outgoing expansions by assuming w = v/\xi is positive and finite at r = \xi = 0. Making the substitution D = \sqrt{AB}, taking z = \kappa T_M^{00} r^2 as the dimensionless density, w = \xi as the dimensionless velocity with \xi = r/t and rewriting the equations in terms of (t, \xi), we obtain

\begin{align*}
zt + \xi \{ -1 + Dw \} z_\xi &= -Dwz, \quad (3.3) \\
wt + \xi (-1 + Dw) w_\xi &= w - D \left\{ w^2 + \frac{1-\xi^2 w^2}{2A} \left[ \frac{1-A}{\xi^2} \right] \right\}, \quad (3.4) \\
\xi A_\xi &= (A - 1) - z \quad \xi D_\xi &= (A - 1) - \frac{(1-\xi^2 w^2)}{2} z. \quad (3.5) \end{align*}

That is, since the sound speed is zero when p = 0, w(t, 0) > 0 restricts us to expanding solutions in which all information from the fluid propagates outward from the center. (Cusp singularities in the velocity at r = 0 in SSC are regularized in co-moving coordinates, [21].)

3.2. A New Ansatz for Corrections to SM. We introduce the following ansatz for corrections to SM near \xi = 0 that involves only even powers of \xi, where we can interpret \xi = r/ct \equiv r/t as a measure of the fractional distance to the Hubble length, [21, 22]:

\begin{align*}
z(t, \xi) &= z_{sm}(\xi) + \Delta z(t, \xi) \quad \Delta z = z_2(t)\xi^2 + z_4(t)\xi^4 \quad (3.7) \\
w(t, \xi) &= w_{sm}(\xi) + \Delta w(t, \xi) \quad \Delta w = w_0(t) + w_2(t)\xi^2 \quad (3.8) \\
A(t, \xi) &= A_{sm}(\xi) + \Delta A(t, \xi) \quad \Delta A = A_2(t)\xi^2 + A_4(t)\xi^4 \quad (3.9) \\
D(t, \xi) &= D_{sm}(\xi) + \Delta D(t, \xi) \quad \Delta D = D_2(t)\xi^2 \quad (3.10)
\end{align*}

where z_{sm}, w_{sm}, A_{sm}, D_{sm} are the expressions for the unique self-similar representation of the SM when p = 0, given by, [22],

\begin{align*}
z_{sm}(\xi) &= \frac{4}{3}\xi^2 + \frac{40}{3\pi}\xi^4 + O(\xi^6), \quad w_{sm}(\xi) = \frac{2}{3} + \frac{2}{9}\xi^2 + O(\xi^4), \quad (3.11) \\
A_{sm}(\xi) &= 1 - \frac{4}{9}\xi^2 - \frac{8}{27}\xi^4 + O(\xi^6), \quad D_{sm}(\xi) = 1 - \frac{1}{9}\xi^2 + O(\xi^4). \quad (3.12)
\end{align*}
This gives

\[ z(t, \xi) = \left( \frac{4}{3} + z_2(t) \right) \xi^2 + \frac{40}{27} + z_4(t) \xi^4 + O(\xi^6), \]

\[ w(t, \xi) = \left( \frac{2}{3} + w_0(t) \right) + \frac{2}{9} + w_2(t) \xi^2 + O(\xi^4). \]

We prove the equations close within this ansatz, at order \( \xi^4 \) in \( z \) and order \( \xi^2 \) in \( w \), with errors \( O(\xi^6) \) in \( z \) and \( O(\xi^4) \) in \( w \). Moreover, the importance of this ansatz is that corrections satisfying the ansatz induce an instability in the SM by creating a uniform spacetime of density \( \rho(t) \), constant at each fixed \( t \), out to errors of order \( O(\xi^4) \). That is, since the ansatz,

\[ z(\xi, t) = \kappa \rho(t, \xi) t^2 + O(\xi^4) = \left( \frac{4}{3} + z_2(t) \right) \xi^2 + O(\xi^4), \quad (3.13) \]

neglecting the \( O(\xi^4) \) error gives \( \kappa \rho = (4/3 + z_2(t))/t^2 \), a function of time alone. For the SM, \( z_2 \equiv 0 \) and this gives \( \kappa \rho(t) = (4/3) t^{-2} \), which is the exact evolution of the density for the SM Friedmann spacetime with \( p = 0 \) in co-moving coordinates, [18]. For the evolution of our specific under-densities in the wave theory, we show \( z_2(t) \to -4/3 \) as the solution tends to the stable rest point, implying that the instability creates an accelerated drop in the density in a large uniform spacetime expanding outward from the center. (See Section 3.7 below.) Finally, we prove in Theorem 6 of the Appendix, that the ansatz (3.11)-(3.13) describes every spherically symmetric solution of the Einstein equations for dust, asymptotically near \( r = 0 \), assuming only that the solution is smooth at \( r = 0 \) in SSC coordinates. In this sense the phase portrait in Figure 1 is universal.

3.3. Asymptotic equations for Corrections to SM. Substituting the ansatz (3.7)-(3.10) for the corrections into the Einstein equations \( G = \kappa T \), and neglecting terms \( O(\xi^4) \) in \( w \) and \( O(\xi^6) \) in \( z \), we obtain the following closed system of ODE’s for the corrections \( z_2(\tau) \), \( z_4(\tau) \), \( w_0(\tau) \), \( w_2(\tau) \), where \( \tau = \ln t \), \( 0 < \tau \leq 11 \). (Introducing \( \tau \) renders the equations autonomous, and solves the long time simulation problem.) Letting prime denote \( d/d\tau \), the equations for the corrections reduce to
the autonomous system

\[ \begin{align*}
    z'_2 &= -3w_0 \left( \frac{4}{3} + z_2 \right), \\
    w'_0 &= -\frac{1}{6} z_2 - \frac{1}{3} w_0 - w_0^2, \\
    z'_4 &= 5 \left\{ \frac{2}{27} z_2 + \frac{4}{3} w_2 - \frac{1}{18} z_2^2 + z_2 w_2 \right\} + 5w_0 \left\{ \frac{4}{3} - \frac{2}{9} z_2 + z_4 - \frac{1}{12} z_2^2 \right\}, \\
    w'_2 &= -\frac{1}{10} z_4 - \frac{4}{9} w_0 + \frac{1}{3} w_2 - \frac{1}{24} z_2^2 + \frac{1}{3} z_2 w_0 + \frac{1}{3} w_0^2 - 4w_0w_2 + \frac{1}{4} w_0^2 z_2. 
\end{align*} \]

We prove that for the equations to close within the ansatz (3.7)-(3.10), it is necessary and sufficient to assume the initial data satisfies the gauge conditions

\[ A_2 = -\frac{1}{3} z_2, \quad A_4 = -\frac{1}{5} z_4, \quad D_2 = -\frac{1}{12} z_2. \]  

We prove that if these constraints hold initially, then they are maintained by the equations for all time. Conditions (3.18) are not invariant under time transformations, even though the SSC metric form is invariant under arbitrary time transformations, so we can interpret (3.18), and hence the ansatz (3.7)-(3.10), as fixing the time coordinate gauge of our SSC metric. This gauge agrees with FRW co-moving time up to errors of order \( O(\xi^2) \).

The autonomous 4 \times 4 system (3.14)-(3.17) contains within it the closed, autonomous, 2 \times 2 sub-system (3.14), (3.15). This sub-system describes the evolution of the corrections \((z_2, w_0)\), which we show in Section 3.4 determines the quadratic correction \(Qz^2\) in (2.1). Thus the sub-system (3.14), (3.15) gives the corrections to SM at the order of the observed anomalous acceleration, accurate within the central region where errors \( O(\xi^4) \) in \( z \) and orders \( O(\xi^3) \) in \( v = w/\xi \) can be neglected. The phase portrait for sub-system (3.14), (3.15) exhibits an unstable saddle rest point at \( SM = (z_2, w_0) = (0,0) \) corresponding to the SM, and a stable rest point at \( (z_2, w_0) = (-4/3, 1/3) \). These are the rest points referred to in the introduction. From the phase portrait, (see Figure 1), we see that perturbations of SM corresponding to small under-densities will evolve away from the SM near the unstable manifold of \((0,0)\), and toward the stable rest point \( M \). By (3.11) and (3.12), \( A_2 = 4/9, D_2 = 1/9 \) at \( (z_2, w_0) = (-4/3, 1/3) \), so by (3.12) the
metric components $A$ and $B$ are equal to $1 + O(\xi^4)$, implying the metric at the stable rest point $(-4/3, 1/3)$ is Minkowski up to $O(\xi^4)$. Thus during evolution toward the stable rest point, the metric tends to flat Minkowski spacetime with $O(\xi^4)$ errors.

3.4. Redshift vs Luminosity Relations for the Ansatz. In this section we obtain formulas for $Q$ and $C$ in (2.1) as a function of the corrections $z_2, w_0, z_4, w_2$ to the SM, we compare this to the values of $Q$ and $C$ as a function of $\Omega_A$ in DE theory, and we show that remarkably, $Q$ passes through the same range of values in both theories.

Recall that $Q$ and $C$ are the quadratic and cubic corrections to redshift vs luminosity as measured by an observer at the center of the spherically symmetric perturbation of the SM determined by these corrections. The calculation requires taking account of all of the terms that affect the redshift vs luminosity relation when the spacetime is not uniform, and the coordinates are not co-moving.

The redshift vs luminosity relation for the $k = 0, p = \sigma \rho$, FRW spacetime, at any time during the evolution, is given by,

$$Hd_\ell = \frac{2}{1 + 3\sigma} \left\{ (1 + z) - (1 + z)^{\frac{1-3\sigma}{2}} \right\}, \quad (3.19)$$

where only $H$ evolves in time, [9]. For pure radiation $\sigma = 1/3$, which gives $Hd_\ell = z$, and when $p = \sigma = 0$, we get, (c.f. [21]),

$$Hd_\ell = z + \frac{1}{4} z^2 - \frac{1}{8} z^3 + O(z^4). \quad (3.20)$$

The redshift vs luminosity relation in the case of Dark Energy theory, assuming a critical Friedmann space-time with the fraction of Dark Energy $\Omega_A$, is

$$Hd_\ell = (1 + z) \int_0^z \frac{dy}{\sqrt{\mathcal{E}(y)}}, \quad (3.21)$$

where

$$\mathcal{E}(z) = \Omega_A(1 + z)^2 + \Omega_M(1 + z)^3, \quad (3.22)$$

and $\Omega_M = 1 - \Omega_A$, the fraction of the energy density due to matter, (c.f. (11.129), (11.124) of [9]). Taylor expanding gives

$$Hd_\ell = z + \frac{1}{2} \left( -\frac{\Omega_M}{2} + 1 \right) z^2 + \frac{1}{6} \left( -1 - \frac{\Omega_M}{2} + \frac{3\Omega_M^2}{4} \right) z^3 + O(z^4), \quad (3.23)$$

9The uniformity of the center out to errors $O(\xi^4)$ implies that these should be good approximations for observers somewhat off-center with the coordinate system of symmetry for the waves.
where $\Omega_M$ evolves in time, ranging from $\Omega_M = 1$ (valid with small errors at the end of radiation) to $\Omega_M = 0$ (the limit as $t \to \infty$). From (3.23) we see that in Dark Energy theory, the quadratic term $Q$ increases exactly through the range

$$0.25 \leq Q \leq 5,$$

(3.24)

and the cubic term decreases from $-1/8$ to $-1/6$, during the evolution from the end of radiation to $t \to \infty$, thereby verifying the claim in Theorem 1. In the case $\Omega_M = .3, \Omega_{\Lambda} = .7$, representing present time $t = t_{DE}$ in Dark Energy theory, this gives the exact expression,

$$H_0d_\ell = z + \frac{17}{40}z^2 - \frac{433}{2400}z^3 + O(z^4),$$

(3.25)

verifying that $Q = .425$ and $C = -.1804$, as recorded in Theorem 1.

In the case of a general non-uniform spacetime in SSC, the formula for redshift vs luminosity as measured by an observer at the center is given by, (see [9]),

$$d_\ell = (1+z)^2r_e = t_0(1+z)^2\xi e \left(\frac{t_e}{t_0}\right),$$

(3.26)

where $(t_e, r_e)$ are the SSC coordinates of the emitter, and $(0, t_0)$ are the coordinates of the observer. A calculation based on using the metric corrections to obtain $\xi e$ and $t_e/t_0$ as functions of $z$, and substituting this into (3.26), gives the following formula for the quadratic correction $Q = Q(z_2, w_0)$ and cubic correction $C = C(z_2, w_0, z_4, w_2)$ to redshift vs luminosity in terms of arbitrary corrections $w_0, w_2, z_2, z_4$ to SM. We record the formulas in the following theorem:

**Theorem 2.** Assume a GR spacetime in the form of our ansatz (3.7)-(3.10), with arbitrary given corrections $w_0(t), w_2(t), z_2(t), z_4(t)$ to SM. Then the quadratic and cubic corrections $Q$ and $C$ to redshift vs luminosity in (2.1), as measured by an observer at the center $\xi = r = 0$ at time $t$, is given explicitly by

$$Hd_\ell = z \left\{ 1 + \left[ \frac{1}{4} + E_2 \right] z + \left[ -\frac{1}{8} + E_3 \right] z^2 \right\} + O(z^4),$$

(3.27)

where

$$H = \left( \frac{2}{3} + w_0(t) \right) \frac{1}{t},$$

so that

$$Q(z_2, w_0) = \frac{1}{4} + E_2, \quad C(w_0, w_2, z_2, z_4) = -\frac{1}{8} + E_3,$$

(3.28)
where $E_2 = E_2(z_2, w_0)$, $E_3 = E_3(z_2, w_0, z_4, w_2)$ are the corrections to the $p = 0$ standard model values in (3.20). The function $E_2$ is given explicitly by

$$E_2 = \frac{24w_0 + 45w_0^2 + 3z_2}{4(2 + 3w_0)^2}. \tag{3.29}$$

The function $E_3$ is defined by the following chain of variables:

$$E_3 = 2I_2 + I_3, \tag{3.30}$$

$$I_{2,3} = J_2 + \frac{9w_0}{2(2 + 3w_0)}, \quad J_3 + 3 \left[ -1 + \left( \frac{8 - 8J_2 + 3w_0 - 12J_2w_0}{2(2 + 3w_0)^2} \right) \right],$$

$$J_2 = \frac{1}{4} \left\{ 1 - \frac{1 + 9K_2}{(1 + \frac{3}{2}w_0)^2} \right\},$$

$$J_3 = \frac{5}{8} \left\{ 1 - \frac{1 - \frac{18}{5}K_2 - \frac{81}{5}K_2^2 + \frac{9}{5}w_0 + \frac{27}{5}K_3 + \frac{81}{10}Q_3w_0}{(1 + \frac{3}{2}w_0)^4} \right\},$$

$$K_{2,3} = \frac{2}{3}w_0 + \frac{1}{2}w_0^2 - \frac{1}{12}z_2, \quad \frac{2}{9}w_0 + w_0^2 + \frac{1}{2}w_0^3 + w_2 - \frac{1}{18}z_2 - \frac{1}{3}z_2w_0.$$  

From (3.29) one sees that $Q$ depends only on $(z_2, w_0)$, $Q(0, 0) = .25$, (the exact value for the SM ), $Q(-4/3, 1/3) = .5$, (the exact value for the stable rest point), and from this it follows that $Q$ increases through precisely the same range (3.24) of DE, from $Q \approx .25$ to $Q = .5$, along the orbit of (3.14), (3.15) that takes the unstable rest point $SM = (z_2, w_0) = (0, 0)$ to the stable rest point $(z_2, w_0) = (-4/3, 1/3)$, (c.f. Figure 1).

3.5. Initial Data from the Radiation Epoch. In this section we compute the initial data for the $p = 0$ evolution from the restriction of the one parameter family of self-similar $a$-waves to a constant temperature surface $T = T_*$ at the end of radiation, and convert this to initial data on a constant time surface $t = t_*$, these two surfaces being different when $a \neq 1$.\footnote{In [21] the authors derived a system of ODE’s on which the SSC equations reduce to ODE’s in the variable $\xi$ when $p = \frac{2}{3} \rho$, and extracted from this the one parameter family of $a$-waves. In this section we use the expansions of $a$-waves into powers of $\xi$ computed in [21]. Interestingly, there are no self-similar perturbations of the SM corresponding to $a$-waves when $p = 0$, c.f. [22, 2].} We then must define a gauge transformation that converts the resulting initial data to equivalent initial data that meets the gauge conditions (3.18). (Recall that condition (3.18) fixes a time coordinate, or gauge, for the underlying SSC metric associated with
our ansatz, and the initial data for the $a$-waves is given in a different
gauge because time since the big bang depends on the parameter $a$, as
well as on the pressure, so it changes when $p$ drops to zero.) The equa-
tion of state of pure radiation is derived from the the Stefan-Boltzmann
Law, which relates the initial density $\rho_*$ to the initial temperature $T_*$
in degrees Kelvin by

$$\rho_* = \frac{a_s c_s}{4} T_*^4,$$

(3.31)

where $a_s$ is the Stefan-Boltzmann constant, [14]). According to cur-
rent theories in cosmology, (see e.g. [14]), the pressure drops precipi-
tously to zero at a temperature $T = T_*$ somewhere between $3000^\circ K \leq
T_* \leq 9000^\circ K$, corresponding to starting times $t_*$ roughly in the range
$10,000\text{yr} \leq t_* \leq 30,000\text{yr}$ after the Big Bang. We make the assump-
tion that the pressure drops discontinuously to zero at some tempera-
ture $T_*$ within this range. That our resulting simulations are numeri-
cally independent of starting temperature, (c.f. Section 3.6), justifies
the validity of this assumption. Using this assumption, we can take
the values of the $a$-waves on the surface $T = T_*$ as the initial data for
the subsequent $p = 0$ evolution. Using the equations we convert this to
initial data on a constant time surface $\bar{t} = \bar{t}_*$, where $\bar{t}$ is the time coor-
dinate used in the self-similar expression of the $a$-waves which assumes
$p = \frac{c_s^2}{\bar{t}} \rho$. Our first theorem proves that there is a gauge transformation
$\bar{t} \to t$ which converts the initial data for $a$-waves at the end of radiation
at $\bar{t} = \bar{t}_*$, to initial data that both meets the assumptions of our ansatz
(3.7)-(3.10), as well as the gauge conditions (3.18).

**Theorem 3.** Let $\bar{t}$ be the time coordinate for the self-similar waves
during the radiation epoch, and define the transformation $\bar{t} \to t$ by

$$t = \bar{t} + \frac{1}{2} q(\bar{t} - \bar{t}_*)^2 - t_B,$$

(3.32)

where $q$ and $t_B$ are given by

$$t_B = \bar{t}_*(1 - \frac{1}{5} \left( \frac{1 + a^2}{1.3 - a^2} \right),$$

(3.33)

$$q = \frac{a^2}{2(1 + a^2)}.$$

(3.34)

Then upon performing the gauge transformation (3.32), the initial data
from the $a$-waves at the end of radiation $\bar{t} = \bar{t}_*$, meets the conditions
for the ansatz (3.7)-(3.10), as well as the gauge conditions (3.18).

Our conclusions are summarized in the following theorem:
Theorem 4. The initial data for the $p = 0$ evolution determined by the self-similar a-wave on a constant time surface $t = t_*$ with temperature $T = T_*$ at $r = 0$, is given as a function of the acceleration parameter $a$ and the temperature $T_*$, by

\[
 z_2(t_*) = \hat{z}_2, \quad z_4(t_*) = \hat{z}_4 + 3\hat{w}_0 (\frac{4}{3} + \hat{z}_2) \gamma ,
 w_0(t_*) = \hat{w}_0, \quad w_2(t_*) = \hat{w}_2 + (\frac{1}{6} \hat{z}_2 + \frac{1}{3} \hat{w}_0 + \hat{w}_0^2) \gamma ,
\]

where $\hat{z}_2, \hat{z}_4, \hat{w}_0, \hat{w}_2$ and $\gamma$ are functions of acceleration parameter $a$ given by

\[
 \hat{z}_2 = \frac{3a^2 - 4}{4} - \frac{4}{3}, \quad \hat{z}_4 = \frac{15a^2(4 - a^2)a^4}{16} - \frac{40}{27},
 \hat{w}_0 = \frac{a}{2} - \frac{2}{3}, \quad \hat{w}_2 = \frac{a^3}{16} (9.5 - 8a^2) - \frac{2}{9},
\]

where

\[
 \gamma = \frac{(1 + a^2)\alpha}{8}, \quad \alpha = \frac{(1 + a^2)}{5(1.3 - a^2)}. \tag{3.35}
\]

The time $t_*$ is then given in terms of the initial temperature $T_*$ by

\[
 t_* = \frac{a\alpha}{2} \sqrt{\frac{3}{\kappa \rho_*}}, \quad \rho_* = \frac{a_s T_*^4}{4c}, \tag{3.36}
\]

The projection of the initial data onto the $(z_2, w_0)$-plane is a curve parameterized by $a$ that cuts through the saddle point corresponding to the SM in system (3.14), (3.15), between the stable and unstable manifold, (the dotted line in Figure 1). This implies that a small under-density corresponding to $a < 1$ will evolve to the stable rest point $(z_2, w_0) = (-4/3, 1/3)$, (c.f. Figure 1).

3.6. The Numerics. In this section we present the results of our numerical simulations. We simulate solutions of (3.14)-(3.17) for each value of the acceleration parameter $a < 1$ in a small neighborhood of $a = 1$, (corresponding to small under-densities relative to the SM), and for each temperature $T_*$ in the range $3000^\circ K \leq T_* \leq 9000^\circ K$. We simulate up to the time $t_*$, the time depending on the acceleration parameter $a$ at which the Hubble constant is equal to its present measured value $H = H_0 = 100h_0 \frac{km}{m_p c}$, with $h_0 = .68$. From this we conclude that the dependence on $T_*$ is negligible. We then asked for the value of $a$ that gives $Q(z_2(t_a), w_0(t_a)) = .425$, the value of $Q$ in Dark Energy theory with $\Omega = .7$. This determines the unique value $a = a = 0.99999959$, and the unique time $t_0 = t_2$. These results are recorded in the following theorem:
Theorem 5. At present time $t_0$ along the solution trajectory of (3.14)-(3.17) corresponding to $a = a_0$, our numerical simulations give $H = H_0$, $Q = .425$, together with the following:

\[
z(t_0, \xi) = (0.192)\xi^2 + (2.871)\xi^4 + O(\xi^6),
\]
\[
w(t_0, \xi) = (0.914) - (0.126)\xi^2 + O(\xi^4),
\]
and
\[
A(t_0, \xi) = 1 - (0.064)\xi^2 - (0.574)\xi^4, \quad (3.37)
\]
\[
D(t_0, \xi) = 1 - (0.016)\xi^2 + O(\xi^4). \quad (3.38)
\]

The cubic correction to redshift vs luminosity as predicted by the wave model at $a = a_0$ is

\[
C = 0.359. \quad (3.39)
\]

Note that (3.37) and (3.38) imply that the spacetime is very close to Minkowski at present time up to errors $O(\xi^4)$, so the trajectory in the $(z_2, w_0)$-plane is much closer to the stable rest point $M$ than to the SM at present time, c.f. Figure 1. The cubic correction associated with Dark Energy theory with $k = 0$ and $\Omega_{\Lambda} = .7$ is $C = -0.180$, so (3.39) is a theoretically verifiable prediction which distinguishes the wave theory from Dark Energy theory. A precise value for the actual cubic correction corresponding to $C$ in the relation between redshift vs luminosity for the galaxies appears to be beyond current observational data.

3.7. The Uniform Spacetime at the Center. In this section we describe more precisely the central region of accelerated uniform expansion triggered by the instability due to perturbations that meet the ansatz (3.7)-(3.10). By (3.13) we have seen that neglecting terms of order $\xi^4$ in $z$, the density $\rho(t)$ depends only on the time. Further neglecting the small errors between $(z_2, w_0)$ and the stable rest point \((-\frac{4}{3}, \frac{1}{3})\) at present time $t_0$ when $a = a_0$, we prove that the spacetime is Minkowski with a density $\rho(t)$ that drops like $O(t^{-3})$, so the instability creates a central region that appears to be a flat version of a uniform Friedmann universe with a larger Hubble constant, in which the density drops at a faster rate than the $O(t^{-2})$ rate of the SM.

Specifically, as $t \to \infty$, our orbit converges to \((-\frac{4}{3}, \frac{1}{3})\), the stable rest point for the $(z_2, w_0)$ system

\[
\begin{pmatrix}
  z_2 \\
  w_0
\end{pmatrix}' = \begin{pmatrix}
  -3w_0 \left(\frac{4}{3} + z_2\right) \\
  -\frac{4}{6}z_2 - \frac{1}{3}w_0 - w_0^2
\end{pmatrix}. \quad (3.40)
\]
Setting $z_2 = -4/3 + \bar{z}(t)$, $w_0 = 1/3 + \bar{w}(t)$ and discarding higher order terms, we obtain the linearized system at rest point $(-\frac{4}{3}, \frac{1}{3})$,

$$
\begin{pmatrix}
\bar{z} \\
\bar{w}
\end{pmatrix}' = \begin{pmatrix}
-1 & 0 \\
-\frac{1}{6} & -1
\end{pmatrix}
\begin{pmatrix}
\bar{z} \\
\bar{w}
\end{pmatrix}.
$$

(3.41)

The matrix in (3.41) has the single eigenvalue $\lambda = -1$ with single eigenvector $R = (0, 1)$. From this we conclude that all orbits come into the rest point $(-\frac{4}{3}, \frac{1}{3})$ from below along the vertical line $z_2 = -4/3$. This means that $z_2(t)$ and $\rho(t) = z_2(t)/t^2$ can tend to zero at algebraic rates as the orbit enters the rest point, but $w_0(t)$ must come into the rest point exponentially slowly, at rate $O(e^{-t})$. Thus our argument that $\bar{w} = w_0 - 1/3$ is constant on the scale where $\rho(t) = k_0/t^{\alpha}$ gives the precise decay rate,

$$
\rho(t) = \frac{k_0}{t^{3(1+\omega)}}.
$$

(3.42)

That is, $\bar{w} \equiv \bar{w}(t) \rightarrow 0$ and $k_0 \equiv k_0(t)$ are changing exponentially slowly, but the density is dropping at an inverse cube rate, $O(1/t^{3(1+\omega)})$, which is faster than the $O(1/t^2)$ rate of the standard model.

Therefore, neglecting terms of order $\xi^4$ together with the small errors between the metric at present time $t_0$ and the stable rest point, the spacetime is Minkowski with a density $\rho(t)$ that drops like $O(t^{-3})$, a faster rate than the $O(t^{-2})$ of the SM. Furthermore, we show that neglecting relativistic corrections to the velocity of the fluid near the center where the velocity is zero, evolution toward the stable rest point creates a flat, center independent spacetime which evolves outward from the origin, and whose size is proportional to the Hubble Length.

We conclude that the effect of the instability triggered by a perturbation of the SM consistent with ansatz (3.7)-(3.10) near the stable rest point $(-\frac{4}{3}, \frac{1}{3})$, is to create an anomalous acceleration consistent with the anomalous acceleration of the galaxies in a large, flat, uniform, center-independent spacetime, expanding outward from the center of the perturbation.

4. Conclusion

The mechanism introduced here for the creation of the anomalous acceleration is derived from a rigorous self-contained mathematical model which identifies a universal unstable mode in the SM on the length scale of the supernova data. The resolution of this instability creates the same anomalous accelerations as the cosmological constant, without assuming it. The model makes testable predictions. If correct, it would imply that we live within a large region of approximate uniform
under-density that is expanding outward from us at an accelerated rate relative to the SM. The idea that the Milky Way lies near the center of a large region of under-density has already been proposed and studied in the physics literature. (See [4] and the Appendix below.)

The central region created by the instability\(^{11}\) is different from, but looks a lot like, a speeded up Friedmann universe tending more rapidly to flat Minkowski space than the SM. The model is based on the starting assumption that Einstein’s equations are correct without the cosmological constant. The result is a verifiable mathematical explanation for the anomalous acceleration of the galaxies that does not invoke Dark Energy.

At this stage we have made no assumptions regarding the space-time far from the center of the perturbations that trigger the instabilities in the SM. The purpose of our paper is not to solve all the problems of Cosmology in one grand solution. Rather, our purpose is to introduce and deconstruct a new instability in the Friedmann space-time of the Standard Model of Cosmology, to identify mechanisms that trigger it, to show how it naturally could account for the anomalous acceleration within Einstein’s original theory without Dark Energy, and then to derive new predictions from it. Given that it is unstable, the paper raises the fundamental question as to whether it is reasonable to expect to observe an unperturbed Friedmann space-time, with or without Dark Energy, on the scale of the supernova data. The consistency of this model with other observations in astrophysics would require additional assumptions.\(^{12}\)

5. Appendix: Regularity at the Center in SSC and LBT

There have been a number of attempts recently to fit the supernova data to local under-densities modeled by the Lemaitre-Tolman-Bondi (LTB) equations in the \(p = 0\) epoch, (c.f. [11, 4, 5] and [37]-[65] of [26], including [28]-[36] listed below). In LTB coordinates, the metric is spherically symmetric and diagonal, particles are assumed co-moving,\(^{11}\)

\(^{11}\)Given the instability of the Friedmann spacetime with respect to small perturbations, one has to wonder about the validity of the assumption that the universe is a Friedmann spacetime even on the scale of the supernova date, with or without Dark Energy.

\(^{12}\)No verifiable model in cosmology currently accounts for all of the physics, [24]. We need only point out the as yet unaccounted for large scale aspherical anomalies observed in the microwave background radiation, [3]. We refer the interested reader to [4] for recent attempts to reconcile other under-density theories, with the standard \(\Lambda CDM\) model of cosmology.
and particle paths are geodesics. It is not difficult to show by construction of an integrating factor [27, 18] that (generically), all metrics in Standard Schwarzschild Coordinates SSC are coordinate equivalent to a metric in LTB form. But metrics in LBT typically exhibit weak singularities in the second derivative at the center. These weak singularities are discussed in [28, 36]. In the most recent paper [36] it is argued that $p = 0$ solutions constructed in LTB coordinates that can account for the anomalous acceleration near the center, also exhibit a “central weak singularity” in the second derivative of the (scalar) density at $r = 0$. Our ansatz does not eliminate the geometric singularity in the second derivative of the metric, and so our results are consistent with [28, 36]. However, by demonstrating that simple wave perturbations from the radiation epoch trigger the instability that creates the anomalous accelerations, provides a plausible explanation for the creation of the singularity at the center, namely, because time-asymptotic wave forms, like rarefaction waves, need not be smooth at the center, c.f. [12]. We now show that our ansatz for the perturbations when $p = 0$ are natural from the SSC point of view because they impose smoothness at the center in an SSC-coordinate sense, a sense we now make precise.

To this end, recall that polar coordinates for $x \equiv (x^1, x^2, x^3) \in \mathcal{R}^3$ take the radial coordinate to be $r = |x|$, and a function given by $f(r)$, $r \geq 0$, represents a smooth spherically symmetric function of $(x^1, x^2, x^3)$ precisely when $f$ is smooth, and satisfies the condition that all odd derivatives of $f$ vanish at the origin $r = 0$. That is, a function $f(r)$ represents a smooth spherically symmetric function of the Euclidean coordinates $x$ at $r = 0$ if and only if the function

$$g(x) = f(|x|)$$

is smooth at $x = 0$. Assuming $f$ is smooth for $r \geq 0$, and taking the $n$'th derivative of $g$ from the left and right and setting them equal gives the smoothness condition $f^n(0) = (-1)^n f^n(0)$. We state this formally as a lemma:

**Lemma 1.** A function $f(r)$ of the radial coordinate $r = \sqrt{|x|}$ represents a smooth function of the underlying Euclidean coordinates $x$ if and only if $f$ is smooth for $r \geq 0$, and all odd derivatives vanish at $r = 0$. Moreover, if any odd derivative $f^{(n+1)}(0) \neq 0$, then $f(|x|)$ has a jump discontinuity in its $n + 1$ derivative, and hence a kink singularity in its $n$'th derivative at $r = 0$.

Lemma 2, the solutions of the Einstein equations (3.3)-(3.6) in SSC that meet our asymptotic conditions (3.7)-(3.10) are necessarily smooth
functions at the origin because the ansatz is even in all the variables $z, w, A, B$. This is consistent with $v = w/\xi$ having odd powers in its expansion, because the velocity is by definition, a derivative, c.f. (3.8). Thus the solutions of the asymptotic equations (3.14)-(3.17) and gauge conditions (3.18) are all smooth at the center in SSC coordinates. We call this SSC-smoothness at the center. We thus have the following theorem:

**Theorem 6.** Let $(z, w, A, B)$ be a smooth solution of the Einstein equations (3.3)-(3.6) that is smooth at $r = 0$, and which has a valid Taylor expansion in $r$ at $r = 0$ up to order $\xi^6$ in $z$ and to order $O(\xi^4)$ in $w, A, B$. Then there exists an SSC time gauge in which the solution satisfies equations (3.14)-(3.17) and (3.18) up to the appropriate orders.

We conclude that in this sense, every spherically symmetric solution of the Einstein equations that is smooth at $r = 0$ in the SSC coordinate sense, is described asymptotically near $r = 0$ by system (3.14)-(3.18). Thus the phase portrait in Figure 1 characterizes the entire space of SSC-smooth solutions near the center. That is, our theorem requires smallness assumptions in $r$, but no smallness assumptions on the variables $(z, w, A, B)$, so the entire space of SSC-smooth large amplitude perturbations of $SM$, (i.e. all smooth solutions), are characterized near $r = 0$ by the two parameter $(w_0, z_2)$ phase portrait of Figure 1. Thus $SM$ is an unstable saddle rest point for all spherical $p = 0$ solutions that are SSC-smooth at the center, and all solutions within the basin of attraction of the stable rest point $M$, will converge (at the appropriate order) to $M$, thereby inducing the same anomalous accelerations (in $Q$) as Dark Energy.

**Acknowledgement:** The authors would like to thank the editors of RSPA for bringing to their attention references [11] and [37]-[65] of [26] on LTB spacetimes.
