Solution. The parametrization \( r(t) = (\cos t)i + (\sin t)j \), \( 0 \leq t \leq 2\pi \), traces the circle counterclockwise exactly once. We can therefore use this parametrization in Equation (4). With
\[
M = x - y = \cos t - \sin t, \quad dy = d(\sin t) = \cos t \, dt
\]
\[
N = x = \cos t, \quad dx = d(\cos t) = -\sin t \, dt,
\]
we find
\[
\text{Flux} = \int_C M \, dy - N \, dx = \int_0^{2\pi} (\cos^2 t - \sin t \cos t + \cos t \sin t) \, dt
\]
\[
= \int_0^{2\pi} \cos^2 t \, dt + \frac{1}{2} \int_0^{2\pi} \cos 2t \, dt
\]
\[
= \left[ \frac{t}{2} + \frac{\sin 2t}{4} \right]_0^{2\pi} = \pi.
\]
The flux of \( \mathbf{F} \) across the circle is \( \pi \). Since the answer is positive, the net flow across the curve is outward. A net inward flow would have given a negative flux.

**16.3 Path Independence, Potential Functions, and Conservative Fields**

In gravitational and electric fields, the amount of work it takes to move a mass or a charge from one point to another depends only on the object's initial and final positions and not on the path taken in between. This section discusses the notion of path independence of work integrals and describes the properties of fields in which work integrals are path independent. Work integrals are often easier to evaluate if they are path independent.
