Problem #1: Let
\[ F(x, y, z) = y \cos(xy) \mathbf{i} + \{x \cos(xy) + z\} \mathbf{j} + y \mathbf{k}. \]

Use the systematic method to find \( f \) such that \( F = \nabla f \).
Problem #2: Let \( F(x, y, z) = \frac{\partial f}{\partial x} i + \frac{\partial f}{\partial y} j \) where \( f(x, y) = x^2 y + y \). Find \( \int_C F \cdot T \, ds \) where \( C \) is the hypo-elliptic-flexical-elastocele, a smooth curve that starts at \( P = (2, 1, 1) \) and ends at \( Q = (-1, 1, 0) \).
Problem #3: Let $\mathbf{F} = x^2 \mathbf{i} + xy \mathbf{j} + y \mathbf{k}$.

(a) Compute $\text{Curl} \: \mathbf{F}$.

(b) Find the circulation per area of $\mathbf{F}$ around the $z$-axis at the point $(x, y, z) = (1, -2, -1)$.

(c) Find the axis around which the circulation of $\mathbf{F}$ is maximal at the point $(x, y, z) = (1, -2, -1)$.

(d) Find the maximum circulation per area of $\mathbf{F}$ at the point $(x, y, z) = (1, -2, -1)$. 
**Problem #4:** Let $S$ be the surface defined by

\[
\begin{align*}
x &= u + v \\
y &= uv \\
z &= v
\end{align*}
\]

as $(u, v)$ ranges over $0 \leq u \leq a, \ 0 \leq v \leq b$. Evaluate the flux $\int \int_S \mathbf{F} \cdot \mathbf{n} \, d\sigma$ of $F$ through $S$ in the direction of positive $y$, where $\mathbf{F} = y\mathbf{i} + x\mathbf{j}$. 
Problem #5: Show that if \( \mathbf{F} = -\frac{y}{2} \mathbf{i} + \frac{x}{2} \mathbf{j} \), then for any closed curve \( C \) in the \((x, y)\)-plane, \( \oint_C \mathbf{F} \cdot \mathbf{T} \, ds = \text{Area enclosed by } C \). [Hint: Green’s Theorem]
Problem #6: In words, the value of the divergence of a vector valued function $F$ at a point $x_0 = (x_0, y_0, z_0)$ is “the flux of $F$ per volume” at $x_0$. State the Divergence Theorem and use it to give a careful derivation of this physical interpretation of $\text{Div} F$. 
Problem #7: The principle of conservation of mass states that the time rate of change of total mass inside a volume $\mathcal{V}$ is equal to minus the flux of mass out through the boundary $\partial \mathcal{V}$. Use the Divergence Theorem to show that if a moving density $\rho(x, t)$ and velocity $v(x, t)$ satisfies the continuity equation $\rho_t + \text{Div}(\rho v) = 0$, then the principle of conservation of mass holds for every volume $\mathcal{V}$. 
Problem #8: When the sun is taken as the origin, a planet moving in planar motion around the sun sweeps out equal area in equal time if its motion \( \mathbf{r}(t) = x(t)\mathbf{i} + y(t)\mathbf{j} \) satisfies
\[
r^2 \frac{d\theta}{dt} = H = \text{constant}.
\]
(Here \( x(t) = r(t) \cos \theta(t) \) and \( y(t) = r(t) \sin \theta(t) \) are the polar coordinates of \( \mathbf{r}(t) \).) Show that if a planet sweeps out equal area in equal time, (as Kepler knew in 1609), then the planet’s acceleration vector \( \mathbf{a} = \ddot{\mathbf{r}}(t) \) points in the direction from the planet to the sun, (as Newton proved in 1687). Said differently, since force equals mass times acceleration, the force is coming FROM the SUN. (EUREKA!!! The sun, NOT the earth, is the CENTER of the UNIVERSE!!!
